HÖGL, O. and WENGER, F. Antioxydantien in Fetten und Ölen. 1. [Anti-oxidants in fats and oils. 1.] WENGER, F. 2. Prüfung von Fetten und Ölen mit dem Swift-Stabilitätstest auf Antioxydantien. [2. Testing fats and oils for anti-oxidants by the Swift stability test.] 3. Einfache Nachweisemethoden für Antioxydantien. [3. Simple methods for detecting anti-oxidants.] *Mitt. Geb. Lebensmittel. Hyg.*, 1954, 45, 335-363; 364-383; 383-388. [Lab. Eidg. Gesundheitsamt., Berne.] French and English summaries.
1. The mechanism of auto-oxidation, methods for estimating the stability of fats and oils, the mode of action of anti-oxidants, anti-oxidants permitted in different countries, and their possible harmful effects are reviewed, with references.
2. A detailed description, with illustrations, is given of apparatus for the Swift stability test, and of the use of the test to detect addition of anti-oxidants to fats. This is possible for animal fats but not where anti-oxidants have been added to inferior or badly handled vegetable fats in the attempt to pass them off as first-class products. Modified working conditions, 115°C. in a current of oxygen of 2.33 ml. per sec., are recommended.
3. Three rapid colour reactions with alcoholic solutions of the fat or oil are claimed to be more sensitive and reliable than the silver nitrate test. Gallates, nordihydroguaiaric acid and guaiac resin, but not thiodipropionic acid or butylhydroxyanisole, are detected with Fe thiocyanate, butylhydroxyanisole by the indophenol reaction with 2 : 6-dichloroquinonechloroimide, and gallates with ammonia, in amounts of 0.05 per cent. or less.

- HOMB, T. En kritisk vurdering av förmiddelanalyser. [A critical survey of analysis of feeding-stuffs.] *Tidsskr. norske Landbruk*, 1954, 61, 259-274.

The review is partly historical, from the first beginnings of Henneberg and Stohmann at the Weende Experiment Station in 1860, and partly concerned with the choice of a method from the plethora of modern proposals. It deals with dry matter (or water), ash, crude protein (according to Kjeldahl), true protein, crude fat, crude fibre and N-free extract. The conclusions for conventional analyses are: until a standard method for water can be agreed, the method used should be stated; there is no reason at present to depart from the conventional "ether extract"; precautions to be taken in the estimation of total N and protein N are outlined; the Weende method for crude fibre is still of value though its original interpretation is not upheld, and recent progress extends the description of a feedingstuff without displacing "crude fibre".—I. Leitch.

- NEVENS, W. B., HARSHBARGER, K. E., TOUCHBERRY, R. W. and DUNCAN, G. H. The ear and leaf-stalk contents of corn forage as factors in silage evaluation. *J. Dairy Sci.*, 1954, 37, 1088-1093. [Dept. Agronom., Illinois Agric. Exp. Stat., Urbana.]

Dry matter (D.M.) was estimated during 5 successive seasons in the ear and leaf stalk of maize at different stages all suitable for silage. Ear D.M. expressed as a percentage of total D.M. in the forage increased rapidly over short periods, e.g., from 11.4 to 48.4 in 25 days. A high positive correlation between ear D.M. and total D.M. enabled the ear content of maize forage, or of maize silage, in which there is little change in D.M., to be predicted. The remaining D.M., in the leaf stalk, remained almost constant. On the assumptions that a bushel of ear maize containing 15 per cent. moisture weighs 70 lb. and that stalks and leaves have 90 per cent. of the feeding value of non-legume hay, the marketable value of maize silage or forage was assessed from the D.M. content. - FRIS-HANSEN, B. The extracellular fluid volume in infants and children. *Acta paediat.*, 1954, 43, 444-458. [Dept. Paediat., Rigshosp., Copenhagen.] French, German and Spanish summaries.

Extracellular fluid volume was estimated by the thiosulphate method of Cardozo and Edelman (*J. Clin. Invest.*, 1952, 31, 280) in 50 children from 1 day to 12 months old. A solution of sodium thiosulphate containing sodium phosphate was

infused intravenously and samples of capillary blood were taken at intervals. Thiosulphate disappears from the blood at a rate proportional to its blood concentration, and on a semi-logarithmic scale the disappearance curve formed a straight line after equilibration, usually in 15 to 20 min. As thiosulphate was excreted rapidly the theoretical concentration at zero time was obtained by extrapolation. From this, taking the plasma protein concentration into consideration, the concentration in plasma water, C_{pw} , was obtained. The extracellular water volume was calculated as $V \times C_s \times 200$, where V was the volume of thiosulphate infused and C_s the concentration of the thiosulphate standard.

Values expressed as a percentage of bodyweight diminished rapidly from 44.1 to 30.4 during the first 6 months of life and then more slowly to 19.6 up to 12 years old. When they were expressed as litres per sq. m. surface area of the body the fall was slight and was mostly during the first month. No difference was found between males and females. Duplicate estimations in 3 subjects differed by 0.4, 2.8 and 0.3 as a percentage of bodyweight.—A. Hepburn.

The construction of respiration chambers with open and closed circuits is described. The closed circuit apparatus presented more technical difficulties, but with animals weighing up to 75 kg. gave more satisfactory results than the open system. The closed circuit chamber has been used for as long as 16 days at a time. Its accuracy was assessed by simultaneous estimations of R.Q. from C and N balances and of the energy value of feed and excreta. Agreement between the results of the 2 methods was good. The precision of the apparatus was such that in 40 pairs of duplicate

N.A. and R., April 1955

experiments 21 pairs of results differed by less than 2 per cent. and only 2 pairs by more than 8 per cent.—D. Duncan.

BRISSON, G. J., ANGUS, W. J. and SYLVESTRE, P. E. Plant pigments as internal indicators of digestibility of dry matter of pasture herbage. *Canad. J. Agric. Sci.*, 1954, 34, 528-532. [Chem. Div., Sci. Serv., Canada Dept. Agric., Ottawa.]

A comparison was made with steers and wethers between the digestibility of the dry matter of pasture herbage estimated by (1) the conventional total collection method, and (2) the chromogen marker technique. The herbage was dried artificially and 4 trials were made with herbage differing in age and quality. There was good agreement between digestibility coefficients estimated by the 2 methods. Optical densities of the pigment extracts were estimated at 10 wavelengths between 395 and 445 $\text{m}\mu$, of which 404 $\text{m}\mu$ gave best agreement with the total collecting technique in steers. With wethers the results from 406 $\text{m}\mu$, which were nearly 4 per cent. above those from 404 $\text{m}\mu$, were almost identical with those of the total collection method. The difference may be due to the higher chromogen content of the younger grass given to the sheep; also, there was probably some destruction of pigment during drying. The chromogen formula developed with data for steers by Reid *et al.* (Abst. 1622, Vol. 22) was applicable also to sheep.—D. M. Walker.

1702

MÜLLER, W. Die Brauchbarkeit von Indikatormethoden bei Verdauungsversuchen mit Geflügel. [The suitability of indicator methods in digestibility experiments with poultry.] *Thesis, Univ. Zürich*, 1953, pp. 89.

Digestibility experiments on fowls are much simplified by the use of indicator methods. By adding to the feed a known amount of an indigestible indicator, and estimating the amount of nutrient per g. indicator in the excrement, the digestibility coefficient can be found without any quantitative estimation of feed intake and excretion as in the standard method. Of the indicators tested Ba sulphate and lignin were regarded as unsuitable because of analytical difficulties, but chromic oxide gave satisfactory results after a pre-period of 5 days. Since the night and day excrements show a difference in chromic oxide content, it is essential that an aliquot portion of the 24-hr. excretion be taken for analysis. As a rule the method gives results somewhat below those obtained by the standard method, but the differences are small, especially for feedingstuffs of good digestibility.—M. B. Richards.

ARMITAGE, P. **Sequential tests in prophylactic and therapeutic trials.** *Quart. J. Med.*, 1954, **23**, 255-274. [Statist. Res. Unit Med. Res. Council, London Sch. Hyg. Trop. Med.]

In this paper the methods and applications of the classical fixed-sample-size test and the sequential

test in assessing the efficiency of prophylactic or therapeutic substances are discussed. The comparisons are made in detail in 2 types of test, (1) where the proportions of successes and failure are compared and, (2) where quantitative comparisons are to be made. One example of the application of the sequential procedure to each case is worked out in detail.

The sequential test will usually, though not always, be more efficient than the equivalent classical test, provided certain conditions are met. Among these are that the test should be "open" and not "closed". An "open" test is allowed to run until a conclusion is reached. A "closed" test is one where some specified number of observations is not to be exceeded. In the latter the classical test is more suitable. Another condition essential for the success of the sequential test is that there should be one criterion only by which the test substances are to be judged.

There is also a discussion on some of the sampling problems encountered in the sequential test.

- CHAPPELL, G. M. Food waste and loss of weight in cooking. *Brit. J. Nutrition*, 1954, **8**, 325-340. [Dept. Household Arts, Queen Elizabeth Coll., Univ. London.]

A table is given of changes in weight of some 70 foods during cooking, expressed as a percentage of raw edible weight. At least a dozen samples of each item were examined but methods were not precisely standardised, since "the work was undertaken to show changes occurring in normal careful domestic cookery". Many of the ranges are wide, but on the whole the mean values tend to agree with those in the literature.

Another table gives the waste during careful preparation of a number of fruits and vegetables, eggs, prawns, plaice and sole, as a percentage of weight as purchased, with values from the literature. Inevitable waste is so high for many foods that avoidance of unnecessary waste is urgent.

The work was done between 1949 and 1952.

- MAYERHOFER, E. Die konservierte Frauenmilch und ihre Sammelstellen von 1907 bis heute. [Preservation of human milk and the collecting centres from 1907 till to-day.] *Öst. Ztschr. Kinderheilk.*, 1954, **10**, 127-140. [Medveščak 73, Zagreb.]

A historical sketch is given of 50 years' experience in the preservation and storage of excess human milk for use with weak and dangerously sick infants. The project first took form in 1907 when the author was attached to the Prague Kinderklinik, and was further developed and organised in Vienna from 1909 to 1914, in cooperation between the author at the Franz-Joseph Hospital and Dr. Příbram at the Vienna Serum Institute. The method was a modification of that of Budde; the milk, up to 100 litres daily, was treated with H_2O_2

Vol. 25, No. 2

at 50° to 55° C. The technique for handling and for bacteriological control was like that customary for preparing therapeutic sera. It is claimed that denaturation is avoided and the natural biological properties of the milk are retained by the Budde method. The milk could be preserved liquid or dried *in vacuo*.

Descriptions are given of the subsequent organisation of human milk banks in Germany, the United States and Belgium, and by the author in Yugoslavia. Of the methods employed, the author commends, in addition to his own, freezing and addition of antibiotics. Sterilisation by prolonged heating up to 100° C. is condemned as damaging the natural properties of the milk.

Protest is made against any commercialisation of preserved human milk. Preservation should be organised in connection with a hospital and a reasonable fee should be charged, as is usual with blood required for transfusion.—H. Chick.

muscle tissue. *Food Res.*, 1954, **19**, 543-556; 557-563. [Amer. Meat Inst. Found., Chicago, Ill.]

For part 2 see Abst. 2827, Vol. 24. [No reference to part 3.]

4. Slices of biceps femoris and semimembranosus muscles were frozen at -150° , -80° or -17° C. before being lyophilised at pressures between 0.001 and 0.3 mm. Hg. The rate of removal of water was uniform and faster than by warm air methods. On rehydration all samples took up moisture to between 85 and 90 per cent. of their original content and the diameters of muscle fibres returned to between 89 and 98 per cent. of their original size. Freeze-drying proceeded inward from the surface and partly lyophilised muscles contained an unaltered central core. Drying of such samples could be completed at temperatures of from 65° to 70° C. without much effect on the quality of the product when reconstituted. If such a two-stage method could be devised on a large scale there might be a considerable saving in cost compared with complete freeze-drying.

5. Conditions likely to affect the rehydration of frozen-dried muscle were investigated in samples of the same 2 muscles and in others of semitendinosus. Rehydration was faster and more complete in samples cut across the fibre than in those cut lengthwise. The temperature at which it took place, 22° or 55° C., affected neither the rate nor the extent of rehydration. With increasingly hypertonic solutions the extent of rehydration decreased; irrespective of its osmotic pressure a salt solution at pH about 7 gave the highest level. Samples rehydrated *in vacuo* took up moisture faster and to a greater extent than did those treated under ordinary pressure.—D. Harvey.

LUTJEN, A. F. M. G. Changes in Dutch salted matjesherring during storage and spoilage. *Proc. Symposium on Cured and Frozen Fish Techn.* Swedish Inst. Food Preserv. Res., Gothenburg, November 1953, pp. 12.

Samples of matjesherring [immature herring] with salt content ranging from 4.8 to 13.5 per cent. were canned and stored at -5° , -2° , 0° and $+2^{\circ}$ C. and at intervals up to 600 days bacterial counts and organoleptic tests were made and pH, acidity and Lea peroxide number of fat, tyrosine by the Folin Ciocalteu reagent, ammonia and trimethylamine by micro-diffusion in Conway units, and volatile acids by the method of Friedemann and Brook (Title 37, Vol. 8; see also Abst. 4218, Vol. 17) were estimated.

Bacterial counts were not related to storage temperature, salt content or degree of spoilage. Formation of tyrosine, ammonia and trimethylamine was favoured by higher temperature and

lower salt content. Volatile acids were more sensitive to temperature than to salt content. Samples with 6.5 per cent. salt kept for 300 days at -5° or -2° C., those with 9.4 per cent. salt for 300 days at $+2^{\circ}$ C. and 600 days at 0° C. or below. The type of spoilage in lightly and heavily salted herring was different. It was concluded that neither tyrosine nor ammonia nor trimethylamine estimation is a satisfactory criterion of spoilage in matjesherring. Estimation of volatile acids was more promising, the limiting value being from 60 to 80 ml. 0.01 N NaOH per 100 g. fish, but is useless for herring delicacies prepared with acetic acid.—W. M. Deans.

SHAMMAS, E. and ADOLPH, W. H. Nutritive value of parboiled wheat used in the Near East. *J. Amer. Dietetic Assoc.*, 1954, **30**, 982-983. [Dept. Biochem., American Univ. Beirut, Lebanon.]

A description is given of the preparation of parboiled wheat in the Lebanon. The proximate composition and vitamin B₁, riboflavin and nicotinic acid contents of parboiled wheat and the wheat as harvested are tabulated. According to the text three-quarters of the riboflavin and one-quarter of the vitamin B₁ and nicotinic acid of wheat are lost in the process. [The tabulated values for nicotinic acid show no loss.] Tests with weanling rats showed that parboiled wheat as sole food for 30 days was equal in growth-promoting value and protein efficiency to the same quantity of whole wheat. Attention is drawn to the possibility of introducing parboiled wheat into the diet of rice-eating people in times of rice shortage and wheat surpluses.—F. C. Aitken.

1725
CUENDET, L. S., LARSON, E., NORRIS, C. G. and GEDDES, W. F. The influence of moisture content and other factors on the stability of wheat flours at 37.8° C. *Cereal Chem.*, 1954, **31**, 362-389. [Dept. Agric. Biochem., Univ. Minnesota, St. Paul.]

Different grades of white and whole wheat flour milled from a hard wheat mix, some of which had been treated with chlorine dioxide (ClO_2), were stored at 37-8°C. With whole wheat flour the effects on stability of treatment with anti-oxidants, of heat treatment and of storage at low oxygen tensions were investigated. After storage in sealed containers at moisture levels of 3, 6, 10 and 14 per cent, the flour samples were used for experimental baking, examination of the physical properties of the doughs and chemical investigation of hydrolytic and oxidative changes in the lipids.

The stability of the flour samples depended on their degree of refinement, treatment with ClO_2 and the moisture content of the stored product. The baking quality of unbleached short patent flour which had been stored for 38 weeks at 3 and 6 per cent. moisture content showed little change; at 10 and 14 per cent. moisture the loaf volume decreased greatly after storage of the flour for 38 and 10 weeks, respectively. Development of objectionable odours was promoted when the storage moisture was increased from 6 to 10 to 14 per cent.; bleaching shortened the storage time after which odour was noticeable. The development of free fatty acids increased with decreasing flour refinement; it was not affected by bleaching. Replacement of the bulk of the lipid material from whole wheat flour which had deteriorated by lipid from sound flour did not fully restore its baking quality. When treatment with ClO_2 was superimposed on natural ageing, "overtreatment" eventually resulted in a rapid falling off in baking quality; it is suggested that flours destined for prolonged periods of storage should not be treated with oxidising "improvers".—G. F. Garton.

KENNEDY, B. M., FLETCHER, L. R. and SABISTON, A. R. Studies on the incorporation of nonfat milk solids in whole wheat bread. 1. Dough properties and baking tests. *Cereal Chem.*, 1954, **31**, 347-361. [Dept. Home Econ., Univ. California, Berkeley.]

Whole wheat bread containing up to 22 per cent. added non-fat milk solids was baked from 7 commercial flours and from 10 experimentally milled varieties of wheat. The commercial flours tolerated up to 22 per cent. of the milk solids without loss of volume; optimum volumes were obtained with from 6 to 22 per cent. milk solids, depending on the flour. Of the wheats studied, Baart and Turkey and Comanche gave increased volumes with all levels of milk solids up to 22 per cent. and Baart 38 and Wichita showed small increases with the 18 per cent. milk levels. Bunyip 41 and Pawnee showed volume increases with 6 and 12 per cent. milk. Mida and Thatcher tolerated 22 per cent.

Vol. 25, No. 2

milk solids without loss of volume, but Ramona 44 gave decreased volumes with all levels of milk.

1727

BOTHMA, F., WEIJERS, H. A. and VAN DE KAMER, J. H. Boekweitbrood ter vervanging van tarwebrood in het dieet van coeliakiepatiënten. [Buckwheat bread as a substitute for wheat bread in the diet of coeliac patients.] *Voeding*, 1954, **15**, 218-223. [Centraal Inst. Voedingsonderzoek T.N.O., Utrecht.] English summary.

Three recipes and instructions are presented for the baking of buckwheat bread. Protein is supplied as dried whole milk with or without egg, and pH is adjusted with lactic or, in summer, acetic acid.—I. Leitch.

1728

KNYAGINICHEV, M. I., PLOTNIKOV, P. M., BOLKHOVITINA, Y. R., BAZOVSKAYA, K. G. and PROSKURINA, O. V. Soderzhanie kislot v rzhanom teste i khlebe, prigotovlennykh raznymi sposobami. [Acid content of rye bread prepared in different ways.] *Biokhimiya*, 1954, **19**, 96-99. [Leningrad Technol. Inst. Food Indust.]

The dough was fermented at 2 different temperatures, from 28° to 30° and from 34° to 36°C, the usual method being to ferment at the lower temperature. Fermentation at the higher temperature increased the amount of lactic acid in the dough and in the bread and diminished the amount of volatile acids. The amounts of the different acids in percentages of the total acidity of the bread were as follows: lactic acid about 60, volatile acids 32, succinic and malic acids together 4 and tartaric and citric acids together 4. The fermentation process took less time at the higher temperature and also there was less loss of dry matter.—H. Scherbatoff.

1729

PARIHAR, D. B. Free amino-acids in some Indian grown rice samples (*Oryza sativa* Linn.). *Naturwissenschaften*, 1954, **41**, 502. [Defense Sci. Lab., Hillside Rd., New Delhi.]

Water extracts of 8 varieties of rice, 4 raw and 4 parboiled, fresh or stored for 1, 2 or 3 years, were analysed by paper chromatography for amino-acids. The amino-acid pattern was similar in all samples. The proportions of alanine, threonine and glutamic acid and the amounts of lysine and histidine decreased with age. In parboiled rice, tryptophan, methionine, valine, alanine, threonine and glutamic acid were comparable with the amounts found in raw rice stored for the same period. Cystine was present in 3 samples of old rice, but not in fresh ones.—A. Hepburn.

1730

NARAYANA RAO, M., VISWANATHA, T., MATHUR, P. B., SWAMINATHAN, M. and SUBRAHMANYAN, V. **Effect of storage on the chemical composition of husked, undermilled and milled rice.** *J. Soc. Food Agric.*, 1954, **5**, 405-409. [Central Food Technol. Res. Inst., Mysore.]

Raw husked, raw undermilled, parboiled undermilled and raw milled rice were stored in gunny bags for 1 year.

The high amylase activity of freshly harvested rice decreased rapidly during storage; cooking quality, as measured by swelling capacity, also improved. Raw milled rice swelled more than raw undermilled or husked rice.

All the samples showed a loss of 20 to 30 per cent. of vitamin B₁ except parboiled undermilled rice, which had a considerably smaller loss. Total N and digestibility of the protein remained almost constant, but N soluble in 3 per cent. NaCl decreased, indicating denaturation.

At the end of storage a rancid odour was noticeable in the husked and parboiled undermilled samples, which were unacceptable to taste. Fat acidity and peroxide values were regularly estimated and were very low for the raw milled rice. On the assumption that rice samples with a peroxide value of 40 were likely to be unacceptable, the storage life in months was computed graphically to be as follows: raw husked rice 7, raw undermilled rice 12, parboiled undermilled rice 11, and raw milled rice 13.—A. Hepburn.

1731

JAGOE, R. B. **An experiment in the storage of under-milled rice.** *Malayan Agric. J.*, 1954, **37**, 154-168.

Sacks of undermilled rice were stored in 3 different rooms, one well ventilated, another not so well ventilated, with fine gauze on the windows and doors, and the third sealed as completely as possible.

Rice in the ventilated rooms kept well for 5 months and then gradually deteriorated in the best ventilated room but in the other room with a lower average relative humidity remained almost unchanged and was in good condition after 20 months. Rice in the sealed room with the highest average temperature and ultimately the highest relative humidity deteriorated most rapidly. Insect pests appeared in all rooms. The higher fat content of undermilled rice as compared with highly milled rice was largely offset by the decomposition of fat on storage, this being least in the rice that kept best. Experiments with rats showed that rice from the sealed room lost about half its vitamin B₁ but rice from the ventilated rooms suffered only slight loss.—A. Hepburn.

1732

HOUSTON, D. F., HUNTER, I. R., McCOMB, E. A. and KESTER, E. B. **Deteriorative changes in the oil fraction of stored parboiled rice.** *J. Agric. Food Chem.*, 1954, **2**, 1185-1190. [Agric. Res. Serv., U.S. Dept. Agric., Albany 6, Calif.]

Three samples of rice, 2 of short-grain Pearl and 1 of long-grain Century Patna, were kept under conditions of open or sealed storage in darkness or in light. Estimations were made of peroxides and of monocarbonyl compounds, mainly aldehydes, and of the free acidity.

In darkness with open storage at 77° F., after an induction period of nearly 200 days each value rose rapidly and rancid odours appeared. Aldehydes and peroxides later fell and the odours disappeared. At higher temperatures, 100° and 140° F., the changes were similar but they happened earlier, at about 100 and 20 days, respectively. With sealed storage induction periods were longer and the odour suggested fermentation, the free acidity curve being flatter than with open storage. Light reduced storage life especially of Pearl rice; this difference is being examined further.

1733

RAYMOND, W. D., SQUIRES, J. A. and WARD, J. B. **The milling of sorghum in Nigeria.** *Colonial Plant Animal Prod.*, 1954, **4**, 152-155.

Experiments were made in milling white and yellow sorghum on a laboratory scale and in a pilot plant which was a modification of the "Maxima" mill commonly used in Commonwealth territories. Analytical data for the two commercial flours, respectively, were vitamin B₁ 2.35 and 2.0, nicotinic acid 31.5 and 33, riboflavin 0.85 and 1.0 µg. per g., total P 218 and 189, phytin 34.6 and 27.7 mg. and crude protein 7.7 and 6.9 g. per 100 g. For the middlings from white sorghum, of which the yield was 12.2 per cent., the corresponding data were 5.4, 77.4 and 1.5 µg. per g., 350 and 30.4 mg. and 10.9 g. per 100 g.

Tests of acceptability to West Africans were made. Both the flours and especially the middlings were popular for cooking by native methods. When baked in a mixture with wheat flour, sorghum flour diminished loaf volume but did not adversely affect flavour.—D. Harvey.

LEE, F. A. **Chemical changes taking place in the crude lipids during the storage of frozen raw vegetables.** *Food Res.*, 1954, **19**, 515-520. [New York State Agric. Exp. Stat., Cornell Univ., Geneva.]

Samples of unblanched or steam-blanching asparagus, maize, Lima beans, snap beans, spinach

N.A. and R., April 1955

and several varieties of peas were frozen and stored at 0° F. for 2.5, 6 or 7.5 years. After lyophilisation the material was extracted with ether in a Soxhlet apparatus to yield crude lipids on which acid value, iodine value and peroxide value were estimated, the latter at intervals of up to 48 days after extraction.

Peroxides found in the lipids of the frozen vegetables tended to decrease when the crude extract was kept for several weeks in a vacuum desiccator over P_2O_5 . Unblanched maize, peas, snap beans and spinach all yielded crude lipids giving high peroxide and acid values. Unblanched asparagus lipids gave no peroxide value, except after the longest periods of storage (7.5 years), but showed high acid values. Maize was the only blanched vegetable of which the lipids were peroxidised to any extent; this suggested that some non-enzymic agent was involved. Iodine values showed considerable variation and it was concluded that they were of little use as an index of changes in crude lipids.—G. A. Garton.

1735

PARIAR, D. B. Changes in the saccharides of stored-pulses. A study by circular paper chromatography. *Naturwissenschaften*, 1954, **41**, 427-428. [Minist. Defence, New Delhi.]

Circular paper chromatography, with *n*-butanol : acetic acid : water (40 : 10 : 50) as solvent and aniline diphenylamine phosphate as detecting reagent, of purified and concentrated aqueous extracts of *Ocifer arietinum*, Linn., *Lens esculenta*, Moench, *Cajanus indicus*, Spreng, *Phaseolus mungo*, Linn., and *Phaseolus aureus*, Roxb., fresh or after storage in closed tins at about 30° C. for 2½ years, showed that fructose and glucose were always formed on storage, and galactose sometimes. Sucrose and raffinose were present in all samples, also unidentified substances travelling more slowly than raffinose.—W. M. Deans.

1736

CZHRNCIIV K., N. Calidad y estabilidad de algunos productos criollos enlatados. [Quality and stability of some indigenous foods canned.] *Arch. venezol. Nutricion*, 1954, **5**, 135-145. [Lab. Indust. Conserv., Ocumare del Tuy.] English and German summaries.

Observations made on tinned native products, kept for varying periods at from 85° to 90° F., demonstrate the stability of their nutritive properties, both analytical and organoleptic, if they have been well processed. The storage life in a tropical climate is given provisionally as 2 years for tomatoes, 1 year for tomato juice, 2 years for papaya juice and 1½ years for "cambures" in syrup. The "cambur", of which there are several varieties, is a fruit similar to the banana. The tinned

products are rich in vitamins A and C, especially papaya juice. This juice has also colloidal properties which would make it suitable for use as a natural emulsifier in the manufacture of sauces.

EAGLE, E., BIALEK, H. F., DAVIES, D. L. and BREMER, J. W. Detoxification of cottonseed by salts and alkalis. *J. Amer. Oil Chem. Soc.*, 1954, **31**, 121-124. [Res. Labs., Swift and Co., Chicago, Ill.]

Samples of hexane-extracted cottonseed meal were treated with (1) dry heat, (2) moist heat, (3) moist heat in the presence of salts or alkalis. Treatment 1 was ineffective and meal 2 was only partly detoxified as tested by inclusion at a level of 67 per cent. in the diets of rats. Treatment 3 was more effective, alkalis being better than salts. The best results were obtained with NaOH, the order of decreasing effectiveness being NaOH, KOH, NH_4OH , $Ca(OH)_2$.

The residual toxicity for rats could not be related to the free gossypol content of the treated meal.—D. H. Shrimpton.

1739

THURBER, F. H., VIX, H. L. E., PONS, W. A. (Jr.), CROVETTO, A. J. and KNOEFFLER, N. B. The effect of processing conditions on the properties of screw-press cottonseed meal and oil. *J. Amer. Oil Chem. Soc.*, 1954, **31**, 384-388. [S. Reg. Res. Lab., New Orleans, La.]

Four series of experiments are reported, the seeds used being low in free fatty acids (0.6 to 1.9 per cent.) and with a moisture content from 7 to 12 per cent. In every case the seed was de-linted and hulled to yield final meals with crude protein content 41 per cent. In each series, 3 types of cooking conditions were used: (1) normal mill practice, moisture 6.6 to 11.4 per cent., temperature 239° to 250° F., duration 30 to 75 min.; (2) low-temperature dry cooking, moisture 7 per cent., temperature 160° to 200° F., duration 22 to 45 min.; (3) wet low-temperature cooking followed by evaporative cooling, moisture 12 to 18 per cent., temperature 216° to 228° F., duration 45 to 65 min.

Meals were analysed for moisture, oil, total N, free and total gossypol and N soluble in 0.5 *M* NaCl. Oils were analysed for free fatty acids, refining loss, refined colour, bleach colour, and total gossypol. All meals were low in free gossypol

(< 0.050 per cent.), but protein quality of meals prepared by methods 2 and 3 was superior. By method 2, little gossypol was bound, but by method 3, 90 per cent. of the gossypol was bound. Oils prepared by methods 2 and 3 were also superior, but there was no direct relation between processing variables and the amounts of gossypol in the oils.

ARCHIBALD, J. G., BLAISDELL, M. L., GERSTEN, B. and KINSMAN, D. M. Grass silage: a reappraisal. *Massachusetts Agric. Exp. Stat. Bull.* No. 477, May 1954, pp. 22. [Amherst, Mass.]

The results of 18 years' experience with grass silage are reviewed.

Good silage is indicated by a pH of about 4.5 or less, a low volatile base content, 3 to 5 per cent. or less of lactic acid and 2 per cent. or less of butyric acid. The relations between these and other constituents show that the estimations of water, pH and protein are sufficient for the judging of silage quality. Good silage is usually greenish brown or yellowish brown. Odour and consistency (absence of sliminess) often indicate the quality. Water below 60 per cent. induces mould; above 70 per cent. there is a risk of poor silage and at 75 per cent. almost a certainty. As the most nutritious forage crops always contain over 70 per cent., wilting of the crop or the use of preservatives or conditioners is essential. Silage to which preservatives had been added were superior in chemical composition, dry matter, energy value, odour and palatability.

Preservatives are either fermentable carbohydrates which promote the production of lactic acid, e.g., molasses, ground cereal grain, or mild antiseptics which prevent the breakdown of

protein and formation of butyric acid or both, e.g., liquid SO_2 and sodium bisulphite. Conditioners are dry materials, e.g., citrus meal, beet pulp, chopped hay and ground grain, which absorb excess moisture. Ground grain is easily applied, 80 per cent. or more of the feeding value being retained, and makes excellent silage. Liquid SO_2 is a good preservative if uniformly applied, but the task is irksome and requires special equipment. Sodium bisulphite acts by slow evolution of SO_2 on contact with the moist green crop; it is cheap and easily applied and makes excellent silage surpassed only by that made with hominy meal or ground wheat. Citrus meal does not produce such high quality, nor does molasses, which is difficult to apply and is no longer recommended.

Structures recommended for storing silage in addition to the upright silo are the temporary one made from a ring of snow fence lined with strong building paper, with a similar section superimposed when filled, and the trench silo. In the trench adequate drainage from the base and the exclusion of surface water are necessary.—A. Hepburn.

1744

ARCHIBALD, J. G. and KUZMESKI, J. W. Further observations on the composition of grass silage. *J. Dairy Sci.*, 1954, **37**, 1283-1290. [Massachusetts Agric. Exp. Stat., Amherst.]

A summary of analyses of grass silage from 1937 to 1953 is presented. Quality in silage as judged by low pH, low content of volatile bases and butyric acid and high content of lactic acid was best attained by the addition of sodium metabisulphite, ground wheat or hominy meal. Preservatives in general gave good conditions. Liquid SO_2 or sodium metabisulphite gave the highest sugar content. High moisture content was associated with a high content of fibre and butyric acid and, except in silages preserved with SO_2 or sodium metabisulphite, indicated poor quality.

1746

MARTIN, J. and BUYSSSE, F. Onderzoek naar de waarde als silcermiddel van enkele nieuwere producten. [Ensiling experiments with some

N.A. and R., April 1955

new products.] *Med. Landbouwhoges. Opzoekingsstat. Gent*, 1952, 17, no. 4, pp. 616-631.

French, English and German summaries.

The results of experiments on the ensiling under pressure, in silos of experimental or practical size, of chopped lucerne or barley with powdered sodium bisulphite, calcium chloride, calcium hypochloride, Formosil, Kofa, or the liquid G₂-30 Sopura (an ester of monobromoacetic acid) were inconclusive. As a guide to quality of silage made with dry powders, or from wilted crops, pH was found unsatisfactory; judged by butyric acid content all the silages were successful, but those made with sodium bisulphite or G₂-30 Sopura were not readily eaten by cattle. Further studies are planned. (From summaries.)

1747

MARTIN, J., and BUYSSE, F. De bruikbaarheid van KOFA als sileermiddel. [The use of KOFA in silage.] *Med. Landbouwhoges. Opzoekingsstat. Gent*, 1953, 18, no. 3, 617-648. English, French, and German summaries.

The use of Kofa powder in silage making was investigated in 4 trials. The first trial compared silage made from unchopped clover with no addition or with Kofa added. Kofa did not affect the pH, but butyric acid decreased and lactic acid increased and the loss of dry matter (DM) and crude protein (CP) and carbohydrates was less.

In the second trial unchopped alfalfa was ensiled with Kofa, with mineral acid or without any addition. In the Kofa silage, compared with the mineral acid silage, pH was higher, butyric acid slightly lower, lactic acid slightly higher and breakdown of protein greater. Compared with silage made without addition, pH was higher, butyric acid much lower and lactic acid higher; protein breakdown was the same.

Chopped alfalfa was used in the third trial. It was ensiled in 4 layers in the same silo: the bottom layer had mineral acid added, the second Sovilon, the third Kofa and the top layer nothing. All 4 layers were comparable in having no butyric acid, sufficient lactic acid and very little protein breakdown.

Finally, unchopped clover without addition, with Kofa, with Formiasil (Amasil) [presumably same as Formosil in preceding Abst.] and with mineral acid, was ensiled. Kofa made the best silage. That made with no addition was poor. As an indication of palatability it was found that animals ate less of the mineral acid silage than of the others, but when digestibility was measured by the lignin method, it had the highest percentage digestibility (63.35), followed by Kofa (56.87), Formiasil (55.57) and untreated (52.07).

HALL, H. H., ETCHHELLS, J. L., JONES, I. D. and LEWIS, W. M. Microbiological and chemical studies of sweet potato vine silage. *J. Dairy Sci.*, 1954, 37, 1325-1336. [Agric. Res. Serv., U.S. Dept. Agric.]

Experimental silage was made in barrels and glass jars with sweet potato vine, including leaf, 100 per cent.; vine 85 and tubers 15 per cent.; and vine 83.5, tubers 13.5 and molasses 3 per cent. With all, fermentation was of acid type, giving silage of good odour, colour and texture. The population of acid-forming bacteria, mainly *Lactobacillus plantarum*, increased rapidly during the first 5 days, and was not greatly affected by the addition of tubers or molasses. During fermentation there was a fall in pH and sugar content, and lactic acid was formed. More lactic acid was formed when tubers or molasses were added.

FACHMANN, W., KRAUT, H. and SPERLING, H. Nährstoff- und Nährwertgehalt von Nahrungsmitteln. [Nutrient and energy value of foods.] *Die Ernährung*, 1953, No. 11, pp. vi + 58.

This second, revised, edition of food composition tables which first appeared in 1943, after an explanatory introduction gives for some hundreds of classified German foods and beverages the content, in g., of protein, fat and carbohydrate (directly estimated), and the energy value calculated with the factors 4.1, 9.3, 4.1, 3.4, 4.1 for protein, fat, carbohydrate, citric acid and other organic acids, respectively, (1) of the edible substance of 100 g. as retailed, (2) of the same at the producer's or wholesale stage, and (3) of 100 g. edible substance as consumed. Tables 1 and 2 also give percentages of waste. Waste of edible substance in the household is not allowed for; it is estimated to be between 5 and 10 per cent. in Germany at present.

W. M. Deans.

CAMARA-BESA, S. F. and BATACLAN, M. The sodium and potassium content of Philippine foods. 2. Sample daily diets. *Acta med. philipp.*, 1953, **9**, 270-273. [Dept. Biochem., Coll. Med., Univ. Philippines.]

Sodium and potassium were estimated in 9 daily diets at moderate cost prepared in the Institute of Nutrition and in 41 daily diets collected from 7 hospitals or other institutions. The mean values in g. daily were Na 3.43 ± 1.115 and K 2.23 ± 0.683 . Separate analyses of breakfast and of midday and evening meals showed the intake of both Na and K to be highest at midday and lowest at breakfast. Samples of the common sauces, *patis* and *toyo* or soya sauce, contained on the average 108 and 85 mg. Na per ml., and fairly large amounts of K as well. The use of the sauces could add considerable amounts of Na to the diet. A. M. Copping.

of nutrition of the population of São Tomé. 4. Composition of breast milk of natives of São Tomé.] *An. Inst. Med. trop., Lisbon*, 1953, **10**, 1535-1541 (with discussion 1541-1543). *Proc. English summary.*

4. Samples of breast milk were obtained from 50 mothers, natives of São Tomé, aged from 17 to 43 years. Of these samples 28 gave an average protein content of 0.94 g. per 100 ml., range 0.59 to 1.26, and 47 samples gave an average fat content of 2.93 g. per 100 ml., range 1.4 to 4.8. Compared with European or American standards the protein content is slightly below, and the fat content much below, normal. The possible relation between the values found and the diet of the mothers is discussed.—M. B. Richards.

- 1765
WALKER, A. R. P., ARVIDSSON, U. B. and DRAPER, W. L. The composition of breast milk of South African Bantu mothers. *Trans. Roy. Soc. Trop. Med. Hyg.*, 1954, **48**, 395-399. [Human Biochem. Unit, S. African Inst. Med. Res., Johannesburg.]

Two hundred and sixty-six samples of breast milk mainly from South African mothers in a state of poor, average or good nutrition were found on analysis to contain total solids, ash, protein, fat, lactose, Ca and P in amounts comparable with milk from British and American mothers. Ascorbic acid was somewhat less. No relation was found between the composition of the milk and the nutritional state of the mothers. The milk yield was satisfactory for 6 months and babies exclusively breast fed were well nourished. It was concluded that either the role of diet in lactation is over-emphasised or that the body was able to adapt itself to the inferior diet largely composed of maize, bread and legumes.—A. Hepburn.

HIETARANTA, M. and NIEMELÄ, K. Rasva- ja valkuaisainepitoisuuden suhteesta suomalaissessa maidossa. [Relation between the fat and protein contents of Finnish milk.] *Maataloust. Aikakausk.*, 1954, **26**, 148-158. [Dept. Dairy Sci., Univ. Helsinki.] English summary.

In Finland the protein:fat ratio of milk is lower than in other northern countries. During the last 30 years it has fallen, probably owing to an increase in fat content as a result of improved breeding and feeding.

The correlation coefficient for protein and fat in bulk milk was $+0.76 \pm 0.06$, in milk from different herds $+0.535 \pm 0.05$ and in milk from individual cows $+0.432 \pm 0.07$. For fat and casein the correlations were $+0.735 \pm 0.05$, $+0.590 \pm 0.03$ and $+0.277 \pm 0.09$.

Casein in milk from different herds and from individual cows was estimated by the formol titration method. The method was accurate to only ± 5 per cent. in the first case and ± 13 per cent. in the second. Seasonal fluctuations in the relations between casein and the other protein components were also observed, so that the estimation of casein by formol titration cannot be considered of much practical value.—T. D. Bell.

1767

OVERMAN, O. R., KEIRS, R. J. and CRAINE, E. M. Composition of herd milk of the Brown Swiss breed. *Illinois Agric. Exp. Stat. Bull.* No. 567, September 1953, pp. 22. [Urbana, Ill.]

Composite samples representing the 24-hr. milk from each of 39 herds containing in all 933 Brown Swiss cows were analysed monthly for a year. The procedures are described and the results are tabulated in detail.

The average butterfat percentage was 3.97, solids-not-fat 9.16 and total solids therefore 13.13. Total protein was 3.5, lactose 4.9 and ash 0.74 per cent. The mean energy value was 756 Cal. per kg. Results are also given for N fractions and Ca, P, Na, K, Mg and Cl, but these were much more variable.—T. D. Bell.

1768

TRUCCO, R. E., VERDIER, P. and REGA, A. New carbohydrate compounds from cow milk. *Biochim. biophys. Acta*, 1954, 15, 582-583. [Inst. Invest. Bioquím., Fund. Campomar, Buenos Aires.]

Examination by paper chromatography of an extract of cow's milk free from lactose revealed 7 carbohydrate compounds. After acid hydrolysis spots 1 and 2 were shown to contain galactose, glucose, mannose and acetylglucosamine; 3 and 4 were identical with compounds E and D previously isolated from rat mammary glands (Abst. 2555, Vol. 22) and later shown (Trucco and Caputto, *J. Biol. Chem.*, 1954, 206, 901 and unpublished results) to contain lactose and neuraminic acid; 5, 6 and 7 contained lactose, glucose and galactose, the last in greater amount than glucose. Carbohydrates obtained from human milk by Gauhe *et al.* (Abst. 3509, Vol. 24) differed chromatographically, both before and after hydrolysis, from those isolated from cow's milk.—A. Hepburn.

1769

BENNERTS, W. T. Goitre and iodine content of cow's milk. *Nature*, 1954, 174, 973-974. [Lab. Animal Physiol., Agric. Univ. Coll., Wageningen.]

Iodine was estimated in hundreds of samples of milk from dairies in goitre, transitional, non-goitre and coastal areas of the Netherlands. All the

samples were taken on one specified day in summer and in winter in order to get strictly comparable results. The results were statistically analysed by the author's method (Abst. 2771, Vol. 24). The mean percentage I content of summer milk from the 4 areas was approximately half that of milk from the same areas in winter. The mean values for the samples from the goitre areas were approximately half the values from the non-goitre areas. The samples from the coastal areas had the highest mean I content.—B. W. Simpson.

1770

STORRS, F. C. and HIETT-BROWN, W. The incidence of penicillin in milk supplies. *J. Dairy Res.*, 1954, 21, 337-341. [United Dairies Res. Labs., London.]

Two surveys were made during May to September 1951 and February to March 1953 in which, with a strain of *Sarcina lutea*, penicillin was detected qualitatively at a level of 0.08 unit per ml. or above. In positive samples it was estimated. The first survey included 1082 samples from 5 milk plants, of which 2 were cheese factories. Of these, 191 from bulk supplies were negative but of 891 samples from producers' individual churns 15 were positive. The second survey included 557 samples taken at a cheese factory and bulk samples numbering 33 again were negative. Of 441 samples from individual producers 14 were positive and of 23 samples from milk intended for starter culture 2 were positive.

In a herd where 70 per cent. of the cows were being treated all milkings up to the fifth after the administration of penicillin contained amounts likely to inhibit starter action.

The veterinary use of penicillin does not, as yet, give rise to difficulties at cheese factories, but if use of it or other antibiotics becomes more general a system of reporting such use to cheese-makers will become desirable.—D. Harvey.

1771

SADEK, S. E. Penicillin concentration in bovine blood and milk after intramuscular injection and its application in the treatment of mastitis. *J. Amer. Vet. Med. Assoc.*, 1954, 125, 387-390. [Dept. Vet. Pathol. Hyg., Coll. Vet. Med., Univ. Illinois, Urbana.]

1772

MCDOWELL, A. K. R. The properties of New Zealand butters and butterfats. 4. Refractive index and density of the butterfat. *J. Dairy Res.*, 1954, 21, 383-390. [Dairy Res. Inst. (N.Z.), Palmerston North.]

For previous parts see Abst. 2873, Vol. 18; Title 174, Vol. 20; Abst. 2769, Vol. 23.

The refractive index and sp. gr. of the fat of butter from 20 factories were measured every 8 weeks for 3 years. The refractive index ranged from 1.4535 to 1.4571, average 1.4549. Maximum values were found in winter and minimum in summer butterfats. Sp. gr. ranged from 0.8885 to 0.8916, average 0.8904, with maximum in late spring and minimum in autumn.

In both refractive index and sp. gr. there was a difference between the North and South Islands only during the winter.

From samples taken in one year significant correlations were found between refractive index and iodine value, between sp. gr. and saponification value and between sp. gr. and Reichert value.

T. D. Bell.

1773

HANSEN, R. P., SHORLAND, F. B. and COOKE, N. J. The branched-chain fatty acids of butterfat. 5. The isolation of 12-methyltridecanoic acid. *Biochem. J.*, 1954, 58, 358-359. [Fats Res. Lab., D.S.I.R., Wellington, N.Z.]

For earlier studies see Abst. 4086, Vol. 24.

By methods which included hydrogenation, fractional distillation and low-temperature crystallisation, 2 fatty acid fractions were isolated, the analytical characteristics of which corresponded to a C_{14} iso-acid, 12-methyltridecanoic acid. The total amount of this acid present in the original butterfat was estimated to be about 0.05 per cent. of the total fatty acids.—G. A. Garton.

1774

SCHÖRMÜLLER, J. and HUTH, H. Beiträge zur Biochemie der Käsebereitung. 7. Phosphor-bilanzen in reifendem Sauermilchkäse. [Biochemistry of cheese ripening. 7. Phosphorus balances in ripening sour milk cheese.] *Ztschr. Lebensmittel-Untersuch. Forsch.*, 1954, 69, 280-299. [Inst. Lebensmittelchem., Tech. Univ., Berlin, Charlottenburg.]

For previous parts see Absts. 4263, Vol. 24; 220, Vol. 25.

Phosphorus fractions were estimated in sour milk cheese at different stages of ripening, and the P content in several cases was related to that of N. The P:N ratio in the total mass of the ripening cheese was constant, about 1/34. The average P content of the dry substance of skimmed milk cheese was 0.94 per cent., much higher than in pure casein (0.79 per cent.). In the course of ripening a considerable amount of the P and N became acid-soluble. The P:N ratio of the trichloroacetic acid extract tended towards a limiting value of about 0.06. During ripening inorganic phosphate was liberated in considerable amounts in the later stages. Organic P compounds soluble in trichloroacetic acid

increased steadily during ripening. These afford an approximate measure of the stage of ripening of the cheese, are remarkably stable towards acids, exceptionally labile to alkali, and consist mainly of phosphopeptides. The proteins got from cheese by treatment with trichloroacetic acid showed at all stages a constant P:N ratio of about 1/43, which corresponds approximately to that of pure casein. From cheese ripened without salt an alkali-labile phosphopeptide was isolated. It contained 4.32 per cent. P and 11.06 per cent. N, and showed, even with fractionated precipitation, a constant P:N ratio of 1/5.6.

DE VERDIER, C. H. Phosphorus-containing amino acids and peptides from acid hydrolysates of casein and pepsin. *Acta chem. scand.*, 1954, 8, 1302-1303. [Inst. Med. Chem., Univ. Upsala.]

1776

FABRIANI, G., FRATONI, A. and SPADONI, M. A. Amino acidi liberi in alcuni formaggi italiani. [Free amino-acids in some Italian cheeses.] *Quad. Nutrizione*, 1952, 12, 475-485. [Ist. Naz. Nutriz. C.N.R., Rome.] French, English and German summaries.

Free amino-acids were estimated by paper chromatography in extracts of Italian cheeses of 4 types, Parmesan, Pecorino, Provolone and Emmenthal. The total and soluble N and amino-acid contents of 16 samples are tabulated.

Parmesan, Provolone and Emmenthal were very rich in glutamic acid, leucine, valine and proline, which were thought to be important in the development of their flavour. Pecorino was more variable in composition; glutamic acid appeared to be decarboxylated during ripening, with formation of γ -aminobutyric acid. Asparagine and glutamine were present in appreciable amounts in Provolone and Emmenthal.—D. Dunnean.

1777

BOOGAERDT, J. Instability of milk due to a high content of calcium ions. *Nature*, 1954, 174, 884. [Lab. Vet. Biochem., Univ. Utrecht.]

In 4 samples of milk showing the Utrecht abnormality (see Absts. 4240, Vol. 17; 1289, Vol. 23) the amount of Ca ions was estimated by the method of Smeets and Seekles (Abst. 1565, Vol. 22). The amounts of ultrafiltrable Ca were 44, 34, 45 and 54 mg. per cent., normal 26 to 46, and of Ca ions in the ultrafiltrate 14.8, 15.2, 20 and 27 mg. per cent., normal 8.0 to 14.4. The data confirm that a high content of Ca ions is the cause of the abnormality.—D. Harvey.

1778

JOSHI, N. V. and RAJ, H. **Microbiological assay of essential amino acids in the milk of Indian buffalo.** *Indian J. Dairy Sci.*, 1954, 7, 139-146. [Maharashtra Assoc. Cultivation Sci., Poona 4.]

The 8 essential amino-acids plus histidine, arginine and cystine estimated microbiologically in the milk protein from Mehsana buffaloes were in amounts similar to those reported for cow's milk. A. Hepburn.

1779

LEONHARD, I. **Poiównanie składu chemicznego mleka owiec różnych ras.** [Comparison of the chemical composition of milk from ewes of different breeds.] *Rocz. Nauk rol. [B]*, 1954, 68, 21-52. [Inst. Zootech., Lab. Centralne, Pracownia Mleczarska.] Russian and English summaries.

Observations were made on the yield and composition of milk from ewes of different breeds in the Grodziec area between April and September 1952. All the breeds, except the Friesian, showed a slightly higher yield than previously recorded. The Friesians had a higher yield in lowland (Grodziec) areas than in highland, and the better feeding and care on the Grodziec farms improved the yield of primitive Zacksels.

The highest yielding breeds were Polish Highland and Friesian. The highest dry matter (DM) content was found in the Berichons and Transylvanian Zacksels. The primitive Zackel, Raczki, Zigay and Zackel-Friesian were intermediate in yield and DM.

Higher milk yield was related to lower fat content; protein and fat increases were related, and increase of fat was associated with decrease of lactose.

Yield dropped during lactation, especially at weaning, and there was a corresponding increase in the percentage of all DM components except lactose, which decreased rapidly during the suckling period. Sp. gr. increased with DM. Higher environmental temperatures caused the fat content to fall.—T. D. Bell.

1780

RZENDOWSKA, F. **Układ enzymatyczny mleka koziego.** [Enzyme studies of goat's milk.] *Rocz. Państwowego Zakł. Hig.*, 1954, 5, 269-286. [Zakł. Badania Żywności i Przedmiotów Użytku PZH.] Russian and English summaries.

1781

KORSHAKOV, P. N. **O nekotorykh osobennostyakh moloka kobylytz.** [Certain characters of mare's milk.] *Konevodstvo*, 1954, No. 5, 32-34. [Dept. Animal Husb., Voronezh Agric. Inst.]

From 2½ to 3¼ months after foaling mare's milk was found to contain from 12.4 to 16 µg. Co per cent., as compared with cow's milk which contained from 3.5 to 7.2 µg. The curative effect of koumiss is ascribed by Prof. Berlin to the high vitamin C content of mare's milk, but the author considers that Co is also of considerable importance. As the Co in the milk depends on the amount in the soils and fodder, mare's milk has a considerably higher Co content in the eastern steppe regions, where the soils and the fodder have a higher Co content. For example, in the Voronezh, Kustanaisk and Aktubinsk regions, the Co content of oats in mg. per kg. dry matter is 1.2, 1.6 and 1.95, and that of hay 0.60, 0.85 and 1.86, respectively. If in the Voronezh region the Co content of a mare's ration of hay and oats, 10 kg. hay, 4 kg. oats [period not mentioned] is taken as 100 per cent., then in the Kustanaisk region it would be 140 per cent. and in the Aktubinsk region 251 per cent. Therefore there would be more cobalt in mare's milk in these 2 regions and the curative quality of koumiss from these sources would be greater.

The increased Co content of the fodder might also be expected to favour synthesis of vitamin B₁₂.—H. Scherbatoff.

Eggs

1782

GRAU, C. R., ALLEN, E., NAGUMO, M., WORONICK, C. L. and ZWIEGART, P. A. **A distinctive yolk component in the fresh eggs of hens fed gossypol.** *J. Agric. Food Chem.*, 1954, 2, 982-986. [Dept. Poultry Husb., Univ. California, Davis.]

Laying hens given cottonseed meal frequently produce eggs with discoloured yolks. A study has been made of this discolouration by comparing the absorption spectra of hexane:acetone (3:1 by volume) extracts of the yolks of eggs from hens fed on diets containing cottonseed meal or pure gossypol with those from hens fed on a standard stock diet. The absorption at 400 mµ. was related quantitatively to the level of gossypol in the diet. The absorption spectra of eggs obtained from hens given cottonseed meal or pure gossypol were qualitatively similar.

It is suggested that the estimation of this yellow component of eggs will serve as a measure of the amount of biologically active gossypol in the diet. D. H. Shrimpton.

Meat (all kinds)

1783

WILSON, G. D., BRAY, R. W. and PHILLIPS, P. H. **The effect of age and grade on the collagen and elastin content of beef and veal.** *J. Animal N.A. and R.*, April 1955

Sci., 1954, **13**, 826-831. [Dept. Animal Husbandry, Univ. Wisconsin, Madison.]

Samples of lean meat between the twelfth and thirteenth ribs of 24 cows, 32 steers and 32 calves were allocated to 3, 4 and 4 grades, respectively, 8 in each grade, and collagen and elastin were estimated. In each age group variation in collagen and elastin was considerable within grades, but the differences between grades were not significant. Meat from cows, steers and calves contained, on the average, 1.84, 1.89 and 2.96 per cent. collagen and 0.49, 0.52 and 1.03 per cent. elastin on a dry, fat-free basis. As veal is more tender than meat from older animals, collagen and elastin were concluded not to be a measure of toughness.

A. Hepburn.

1784

SHORLAND, F. B. Occurrence of fatty acids with uneven-numbered carbon atoms in natural fats. *Nature*, 1954, **174**, 603. [Fats Res. Lab., D.S.I.R., Wellington, N.Z.]

Pure *n*-pentadecanoic acid was isolated from hydrogenated mutton tallow and from hydrogenated liver oil of the shark (*Galeorhinus australis*). The same acid was obtained also from butterfat without recourse to hydrogenation.—G. A. Garton.

1785

HANSEN, R. P., SHORLAND, F. B. and COOKE, N. J. The occurrence of *n*-heptadecanoic acid (margaric acid) in hydrogenated mutton fat. The occurrence of *n*-pentadecanoic acid in hydrogenated mutton fat. *Biochem. J.*, 1954, **58**, 513-515; 516-517. [Fats Res. Lab., D.S.I.R., Wellington, N.Z.]

From the same hydrogenated external carcass fat of sheep as was used in previous investigations (Absts. 1933, 4039, Vol. 23), fractions were isolated which were identified as *n*-heptadecanoic (margaric) and *n*-pentadecanoic acids, accounting for 1.2 and 0.15 per cent., respectively, of the fats.

G. A. Garton.

1786

HANSEN, R. P., SHORLAND, F. B. and COOKE, N. J. The occurrence of 10-methyldecanoic acid in mutton fat. *Chem. and Indust.*, 1954, No. 40, 1229-1230. [Fats Res. Lab., D.S.I.R., Wellington, N.Z.]

A fraction was isolated which corresponded in analytical characteristics to the C_{13} *ante*-*iso*-acid, 10-methyldecanoic acid.—G. A. Garton.

Fish

1787

PATHAK, S. P. and SUWAL, P. N. Component fatty acids of marine fish liver oils. *J. Amer. Oil Chem. Soc.*, 1954, **31**, 332-334. [Dept. Indust. Chem., Banaras Hindu Univ., India.]

Vol. 25, No. 2

The mixed fatty acids were obtained by saponification of the liver oils of the shark *Carcharias melanopterus* and the saw-fish, *Pristis cuspidatus*, both caught in the Bay of Bengal. The acids were separated into groups of differing unsaturation by the lithium salt and acetone and lead salt and ethanol procedures and were then converted to methyl esters which were analysed by fractional distillation *in vacuo*.

The saturated acids totalled 31.1 and 36.9 per cent. of the total acids of the shark and saw-fish oils, respectively, and contained mainly palmitic and stearic acids, with small amounts of myristic acid. The unsaturated acids of both oils were mainly C_{16} , C_{18} , and C_{20} , of a similar order of unsaturation in both; C_{22} and C_{24} unsaturated acids were also present in both oils, to a greater extent in shark oil; this accounted for the higher iodine value of the original oil.—G. A. Garton.

1788

SWAIN, L. A. Fatty acid composition of fish oils. 3. Sockeye salmon offal oil. *Fish. Res. Board Canada, Progr. Rep. Pacific Coast Stat.*, 1954, No. 99, 6-8. [Pacific Fish. Exp. Stat.]

Methyl esters were prepared from the fatty acids of 6 samples of alkali-refined offal oil of sockeye salmon (*Oncorhynchus nerka*). The composition was established by the usual ester-fractionation technique. The major component acids were palmitic and unsaturated acids of the C_{18} , C_{20} and C_{22} series.—G. A. Garton.

FOODSTUFFS OF VEGETABLE ORIGIN

General

1789

TAHA, M. M. Phytic acid distribution in foodstuffs. Its relation to calcium and total phosphorus. *J. Egypt. Med. Assoc.*, 1954, **37**, 629-637. [Biochem. Dept., Fac. Med., Alexandria.]

Egyptian foods were analysed for Ca, total P by Brigg's method, and phytic acid P by the method of McCance and Widdowson (Abst. 4339, Vol. 5). Of the cereals tested, maize flour, wheat flour, wheat bran, millet and barley, the last 3 had the highest content of phytic acid P, amounting to from 43 to 53 per cent. of the total P; all had a relatively low Ca content. Polished rice, with 102 mg. Ca per 100 g. and no phytic acid P, was an exception.

The legumes analysed, lentils, kidney beans, peas, cowpeas, broad beans and fenugreek, had a high Ca content ranging from 121 to 217 mg. per 100 g., but also a very high total P, from 400 to 660 mg. per 100 g., of which from 20 to 67 per cent. was phytic acid P. If the ratio of P to Ca in Ca phytate is taken as 1.25 (Abst. 766, Vol. 17),

it is calculated that all the Ca would be precipitated, leaving no available residue.

All the nuts tested were rich in total and phytic acid P; the almond and hazelnut contained more Ca and less phytic acid P than the walnut. Vegetables and fruits were generally relatively rich in Ca and poor in phytic acid P. None or a trace only was detected in tomatoes, carrots, green beans, spinach, cauliflower, cabbage, radishes, celery and beetroot. Of the fruits tested, significant amounts of phytic acid P were found in apricots and dates.

1790

DOS SANTOS CARVALHO, J. Composição de alguns alimentos exóticos e seus nomes vulgares. [Composition of some foreign foods and their common names.] *An. Inst. Med. trop., Lisbon*, 1953, 10, 1555-1561. *Proc.* English summary.

Nutritionists are often seriously hampered in their efforts to improve the native diet in overseas territories through lack of knowledge of the composition and energy value of the local foods, information which is generally not to be found in current treatises on tropical medicine. A vocabulary is given of 36 foods, with the botanical name, the English (and sometimes the French) equivalent, and the native name in different territories such as Angola, Timor, Mozambique, Zambesi and Congo. The chemical composition, including in most cases values for protein, fat, carbohydrate, fibre, energy, Ca, P and vitamins A, B₁, B₂, C and PP, is given.—M. B. Richards.

1791

DE LIZ GRILLO ABREU VELHO, H. Composição química de alguns produtos de origem vegetal utilizados na alimentação dos indígenas. [Chemical composition of plant products used as food by natives.] *An. Inst. Med. trop., Lisbon*, 1953, 10, 1563-1582. *Proc.* English summary.

The nutrition problems of the natives of Angola are presented in a general way. A regional map shows the zones of predominance of the different cereals, cassava, maize and different types of millet, which in the form of flour mixed with water make up the basis of the diet. For 13 samples of cassava flour, decorticated and sun-dried, the average percentage composition was protein 1.74, carbohydrates 79.75, fat 0.78, fibre 2.02, minerals 1.78, moisture 13.93. For cassava flour, previously macerated in water, the values for 11 samples were about the same, except for protein 1.47, fat 0.41 and fibre 1.84. For 11 samples of maize flour the percentage of protein was 8.37, carbohydrate 72.44, fat 3.71, fibre 1.11, minerals 1.43, and moisture 12.94. For great millet, protein 10.84,

carbohydrate 60.13, fat 4.31, fibre 2.03, minerals 1.99 and moisture 11.66. For 6 samples of sweet potato, which is universally cultivated, the percentage composition was protein 1.56, carbohydrate 33.62, fat 0.36, fibre 0.88, minerals 1.02 and moisture 62.54.

Fifteen samples of bean gave protein 20.99, carbohydrate 57.34, fat 1.76, fibre 4.26, minerals 3.91, and moisture 11.74, and 7 samples of groundnut gave protein 29.00, carbohydrate 12.29, fat 45.19, fibre 3.60, minerals 2.33 and moisture 7.60. Other vegetable foods used, some cultivated, some wild, include pumpkins, yams, mushrooms, the green leaves and tender parts of plants and trees, and fruits. Foods of animal origin are little used in general, although cattle are reared in some parts and milk is used to a certain extent. River fish, which are abundant, are dried for commerce, and sea fish, dried and salted, are sent into the interior.

It is suggested that regional investigations should be made with a view to the solution of food problems in the African territories.

1792

LANTZ, E. M., GOUGH, H. W. and JOHNSON, M. M. Nutritive values of some New Mexico foods. *New Mexico Agric. Exp. Stat. Bull.* No. 379, June 1953, pp. 20.

Foods common to the Spanish-speaking inhabitants were examined. Tortillas and other foods made from whole maize treated with lime contained more Ca, vitamin B₁, riboflavin and nicotinamide than tortillas now mostly made from unenriched wheat flour. Beans, which form a large part of the diet, are rich in protein, B vitamins and Fe. Chilli (pepper) is a good source of carotene and ascorbic acid. Much is lost on drying, ascorbic acid almost completely. The nicotinamide content is high and the amount of chilli eaten makes it a valuable source also of vitamin B₁ and riboflavin. Wild greens commonly eaten in rural districts compare favourably in nutritional content with cultivated varieties.

ARROYAVE, G., PIZZATI, S., BRESSANI, R. and MÉNDEZ, J. Contenido de diversos nutrientes en alimentos procedentes de Centro-América. 1. Verduras subterráneas, verduras herbáceas, frutos-verduras y frutas. [Nutrient content of foods from Central America. 1. Roots and tubers, green vegetables, vegetable-fruits and fruits.] *Arch. venezol. Nutricion*, 1954, 5, 61-70. [Inst. Nutricion, Centro-América y Panamá, Guatemala.] English and German summaries.

Seventy-two samples of tubers and roots, green vegetables, vegetable-fruits, and fruits from different parts of Central America were analysed for

N.A. and R., April 1955

moisture, ether extract, crude fibre, N, ash, Ca, Fe, P, carotene, vitamin B₁, riboflavin, nicotinic acid and ascorbic acid. Some of the foods were notable for a relatively high content of certain constituents: for example, blede (*Amaranthus hybridus*), chipilin (*Crotalaria longirostrata*), and macuy (*Solanum nigrum*) were high in Ca, and were good sources of Fe, carotene and ascorbic acid. They had also the highest amounts of riboflavin, although none of the foods analysed could be considered a good source of this vitamin. The plants were in general low in vitamin B₁, except for 3 samples of tamarind; numerous plants are mentioned as good sources of carotene, nicotinic acid and ascorbic acid. The table contains the scientific names of all the products analysed, and indicates their origin.

M. B. Richards.

SCHARER, K. and JUNG, J. Der Einfluss der Pflanzenernährung auf den ernährungsphysiologischen Wert der Futtermittel. [Effect of plant nutrition on the nutritive value of feedingstuffs.] *Arch. Tierernährung*, 1954, **4**, No. 4, Beihefte, 107-118. [Agrik. Chem. Inst., Justus Liebig Hochschule, Univ. Giessen.]

In a review of the literature, and with emphasis on the authors' own published and unpublished work, it is shown that fertilisers can influence to an important extent the composition and nutritive value of crops for human and animal consumption. In particular, the oxalic acid content of beet tops and the formation of carotene in fodder plants are discussed; both are influenced by the application of phosphate, nitrogen and potash fertilisers of different forms.—D. Duncan.

Cereals

1796

DEUTSCH, T. Die N-endständigen Aminosäuren der Weizen- und Roggengliadine. [The N-terminal amino-acids of wheat and rye gliadins.] *Acta physiol. hung.*, 1954, **6**, 209-224. [Biochem. Inst., Ungarisch. Akad. Wissenschaften, Budapest.] Russian summary.

Vol. 25, No. 2

N-terminal amino-acids in gliadin of whole wheat flour from spring varieties of ordinary and durum wheat, commercial mixed flour and whole rye flour from 2 varieties were estimated by the 2:4-dinitrofluorobenzene method of Sanger (*Biochem. J.*, 1945, **39**, 507: see also Title 1170, Vol. 23). The dinitrophenyl derivatives of the amino-acids were identified by paper chromatography with citrate as solvent. The reliability of the method was tested with insulin. Full details are given and chromatograms are reproduced.

Gliadin from ordinary wheat was found to have 2 phenylalanine terminal groups and that from durum wheat one, but, contrary to the finding of Kőrös (*Magyar Kém. Folyóirat*, 1950, **56**, 131), no histidine terminal group. Gliadin from rye had glutamic acid and phenylalanine terminal groups; one variety was thought to have 4 of the latter, the other 2, but further investigations are in progress.—W. M. Deans.

GILLES, K. A. and SMITH, F. The carbohydrates of the *Gramineae*. 3. A note on the nature of wheat gum.

MONTGOMERY, R. and SMITH, F. 4. Identification of the sugars of the flour of wheat (*Triticum vulgare*). *Cereal Chem.*, 1954, **31**, 488-489; 490-494. [General Mills Res. Lab., Minneapolis, Minn.]

3. A water extract of wheat starch yielded on precipitation with methanol a polysaccharide mixture shown to contain as a percentage glucose 63.2, arabinose 5.3 and xylose 3.2. More highly purified wheat starch contained a glucosan but little or no pentose. The sulphite wash-water from the commercial separation of starch from wheat flour contained a directly precipitable polysaccharide, wheat gum, of percentage composition glucose 58, arabinose 17 and xylose 25.

4. An aqueous alcohol extract of wheat flour was separated by column chromatography on charcoal-Celite into 8 fractions. Each fraction was further separated on large paper chromatograms and corresponding spots from 10 papers were combined and re-chromatographed. By comparison with standard chromatograms glucose, fructose, sucrose and maltose were identified. Elution of the respective spots and conversion to crystalline derivatives verified their identity. The quantities isolated agreed with data reported in part 1 (Abst

4656, Vol. 21). Three unknown spots were obtained; one which behaved chromatographically like melibiose gave only fructose and glucose on hydrolysis, a second was apparently a mixture of raffinose and a glucrofructosan and the third with a mobility between that of raffinose and melibiose was obtained with glucrofructosans.—A. Hepburn.

1799

HARSHBARGER, K. E., NEVENS, W. B., TOUCHBERRY, R. W., LANG, A. L. and DUNGAN, G. H. **Yield and composition of corn forage as influenced by soil fertilization.** *Illinois Agric. Exp. Stat. Bull.* No. 577, June 1954, pp. 19. [Urbana, Ill.]

The yield and composition of 5 maize hybrids under a manurial treatment varying little over the 5 years of the experiment was compared with that of the unmanured crop. Fertiliser increased the dry matter yield of the leaf-stalk and ear fractions proportionately, the response varying with weather conditions in each year. The interpretation of conflicting results on crude protein content is that effects on the ear are influenced by season and that fertiliser increases crude protein in the leaf-stalk fraction only when the crop is grown on soils low in available plant food. Crude fibre percentage is unaffected.—J. L. Corbett.

1800

SNIEGOWSKI, M. S. and BALDWIN, A. R. **Fatty acid compositions of corn oils in relation to oil contents of the kernels.** *J. Amer. Oil Chem. Soc.*, 1954, **31**, 414-416. [George M. Moffett Res. Labs., Corn Products Refining Co., Argo, Ill.]

The oil was extracted with ether from 392 samples of maize kernels. The iodine values of the oils were estimated by the Wijs method and the content of linoleic acid spectrophotometrically after alkali-isomerisation.

The oil content ranged from 1.13 to 13.8 per cent. Iodine values, which decreased with increasing oil content, ranged from 88.4 to 147.4.

The linoleic acid content of the oils also decreased as the percentage of oil in the kernels rose.

1801

LOFLAND, H. B., QUACKENBUSH, F. W. and BRUNSON, A. M. **Distribution of fatty acids in corn oil.** *J. Amer. Oil Chem. Soc.*, 1954, **31**, 412-414. [Dept. Biochem., Purdue Univ., Lafayette, Ind.]

The fatty acid composition of the oil from 13 samples of maize kernels was estimated spectrophotometrically or by ester fractionation. With increasing oil content of the kernels, from 1.6 to

11.5 per cent., a decrease in iodine value and linoleic acid content of the oils was observed.

G. A. Garton.

Roots

1802

WALKER, T. W., ADAMS, A. F. R. and ORCHISTON, H. D. **Some effects of sulphur and phosphorus on the yield and composition of rape (*Brassica napus*).** *N.Z. J. Sci. Technol.*, 1954, **36**, 103-110. [Canterbury Agric. Coll., Lincoln.]

In 2 trials the application of 96 lb. P_2O_5 per acre as monocalcium phosphate significantly increased the yield of rape. The addition of gypsum to supply the amount of sulphur present with this quantity of phosphorus in superphosphate fertiliser gave a further significant yield increase and a higher content of inorganic S in the dry matter in one of the trials. In the other case it is thought possible that the sulphate ion supplied in the gypsum reduced the uptakes of the phosphate and nitrate ions.—J. L. Corbett.

Legumes

1803

MELIÇO SILVESTRE, A. **Contribuição para o estudo da alimentação do indígena das nossas Províncias Ultramarinas. [Contribution to the study of the nutrition of natives of our overseas provinces.]** *An. Inst. Med. trop., Lisbon*, 1953, **10**, 1545-1553. *Proc.*

In connection with the tropical disease kwashiorkor, which is due to deficiency of proteins of high quality, some laboratories are studying the seeds of Leguminosae for their possible prophylactic value. Analytical values are presented for 10 samples of seeds of tropical legumes sent from the Colonial Garden of Lisbon and analysed in the University of Coimbra. The data include moisture, fat, protein, total sugar, reducing sugar, cellulose, ash, Ca, P, K and the vitamins B₁, B₂, PP and C. It is intended to complete the work by estimating the amino-acids of the proteins in these legumes, in which the protein content ranged from 17.0 to 23.0 per cent.

M. B. Richards.

1804

KLIMENKO, V. G. **Formy azota semyan i belkov nekotorykh sortov soi. [Forms of nitrogen in the seeds and proteins of some kinds of soya.]** *Biokhimiya*, 1954, **19**, 3-9. [Plant Biochem. Lab., Univ. Kishinev.]

A study with special reference to varietal differences and the effect of weather in different harvest years on total N and proteins in soya seeds. Variety had no effect and weather had very little on the total N content of the seeds. Preparations

N.A. and R., April 1955

of proteins from soya seeds of different varieties did not differ in S, N or amino-acid content. The amino-acid contents, however, did differ in different harvest years.—H. Scherbatoff.

1805

CALÉ, M. T., SPADONI, M. A. and TECCE, G. Frazione dell'azoto solubile dei semi di pisello in germoglio. [The soluble nitrogen fraction in the germinating pea.] *Quad. Nutrizione*, 1952, 12, 527-530. [Ist. Naz. Nutrizione C.N.R., Rome.]

Contrary to previous results with seeds of *Ricinus communis* (*Quad. Nutrizione*, 1952, 12, 389), the increase in soluble N during the germination of peas was not paralleled by a rise in free amino-acids; on the 4th day chromatography revealed appreciable amounts only of α -alanine, and small amounts of glycine, proline, valine and the leucines. On the other hand, acid hydrolysis of the soluble N fraction liberated considerable amounts of aspartic acid, glutamic acid, arginine and lysine and smaller amounts of alanine, γ -aminobutyric acid, serine, valine and the leucines. It is suggested that these amino-acids may be present as acyl derivatives or cyclic compounds, or, as is also possible from Synge's work on ryegrass (*Abst.* 4670, Vol. 21), bound with carbohydrates as in the Maillard reaction.—W. M. Deans.

Fruits

1806

TANNER, H. and RENTSCHLER, H. Über die Zusammensetzung der Fruchtsäuren von schweizerischen Obstsorten. 2. Die Fruchtsäuren der schweizerischen Mostäpfelsäfte. [Composition of organic acids of Swiss fruit juices. 2. Organic acids of juice of Swiss cider apples.] *Mitt. Geb. Lebensmittel. Hyg.*, 1954, 45, 305-311. [Eidg. Versuchsanst., Wädenswil.] French and English summaries.

The fermented juice of 14 kinds of Swiss cider apples was studied by the methods previously used for pear juice (*Abst.* 287, Vol. 25). On the average malic acid accounted for about 85 per cent. of the organic acids, citric acid for only 1 to 3 per cent., much less than in pear juice. Quinic acid was very variable, from 3 to 20 per cent. in different varieties. Glycolic acid was also present in small amount.—W. M. Deans.

VIKELAND, N. Forsøk med beiting og hâslått på eng i Troms og Finnmark. [Experiments in

grazing and haymaking on pastures in Troms and Finnmark.] *Forskning og Forsøk Landbruket*, 1954, 5, 393-409. [Statens Forsøks-gard Holt, Trondheim.] English summary.

It is common practice in these districts to graze either in spring or autumn pastures that are cut for hay in summer. Experimental grazing and cutting of both natural and cultivated (collegiate) fields showed that grazing in spring reduced the yield of hay, probably by more than was harvested by grazing, and that grazing in autumn or cutting twice reduced the total yield of hay in the next season and increased the danger of frost damage in winter and the spread of weeds.—I. Leitch.

1815

HILDER, E. J. and SPENCER, K. The influence of sulphur on a natural medicago pasture. *J. Austral. Inst. Agric. Sci.*, 1954, 20, 171-176. [Div. Plant Indust., C.S.I.R.O., Reg. Pastoral Lab., Armidale, N.S.W.]

On a property in New South Wales lambs were reported to be unthrifty and their wool suggested Cu deficiency. No sign of Cu deficiency was seen in the pasture, but phalaris and burr medic contained only 0.08 and 0.13 per cent. S, respectively. The soil was a black silty clay loam which had never received fertiliser.

Experimental plots were treated with superphosphate and gypsum to give from 9.2 to 67.2 lb. S per acre and from 8.1 to 18.6 lb. P. Both fertilisers gave marked improvement in pasture growth, especially in medic. The total yield of pasture components rose with the amount of S, from 7.7 cwt. dry matter per acre on untreated plots to 30.17 on the plots given 34.8 lb. S and 11.6 lb. P per acre. The percentage of medic rose from 47 to 85, that of total N from 3.64 to 5.14 and that of S from 0.17 to 0.38. There was no effect of the P in superphosphate.

Yellowing of leaves was not seen on control plots, so in severe S deficiency it is not a reliable guide. It appeared in plants given a small dressing of copper sulphate. [The effect on grazing animals is not reported.]—D. Duncan.

BIELIŃSKI, K. and BIELIŃSKA, KR. Zmiany ilości i wartości odżywczej sprzętu lucerny w okresie rozwoju jej vegetacji. [Quantitative changes in feeding value of alfalfa in relation

to stage of growth.] *Rocz. Nauk. rol. [B]*, 1954, 67, 449-472. [Inst. Zootech., Zakł. Doświad. Kółka Wielka.] Russian and English summaries.

Sampling of the alfalfa was at 3-day intervals over 6 weeks from late May to early July. Yield of dry matter per unit area increases up to flowering and thereafter decreases. During the period of growth studies, first nitrogenous and later fat and ash constituents fell and simultaneously fibre content rose. For feeding young stock and high-yielding cows it is therefore advantageous to harvest the crop before budding and flowering. [From English summary.]—D. Harvey.

1818

HARDWICK, N. E. Changes in the major chemical constituents of subterranean clover (*Trifolium subterraneum* L.) during growth. 1. The carbohydrates. 2. The non-carbohydrate fractions and their relationship to the carbohydrates. *Austral. J. Agric. Res.*, 1954, 5, 372-382; 383-391. [Inst. Agric., Univ. W. Australia, Nedlands.]

1. Twelve samples of the Dvalganup variety of subterranean clover were collected at stages between 6 weeks after germination and 3 months after death of the plants. Free and total reducing sugars were low in the vegetative growth stage; at the appearance of buds both rose and later, with the onset of wilting, they fell rapidly. Reserve carbohydrate was highest at the first sampling; fructosans were not detected. Cellulose remained low for a long period but rose, more especially in early wilting; encrusting hemicelluloses were remarkably constant. In these respects subterranean clover resembles other legumes.

2. Four non-carbohydrate components were studied in the same samples. Lignin remained low during growth but rose greatly during wilting. Ethanol-benzene extractives fell rapidly during wilting. In estimations made on only half the samples, ash increased gradually and then fell, and crude protein decreased slowly from the level at the early sampling. The ratio cellulose: lignin was 7 to 8:1 in earlier stages and 4 to 2:1 after wilting.—D. Harvey.

1819

ROBERTSON, H. and BARNETT, A. J. G. The free amino-acids present in fresh and in fermented marrow stem kale. *J. Agric. Sci.*, 1954, 45, 36-40. [Div. Agric. Biochem., Dept. Biol. Chem., Univ. Aberdeen.]

Kale-water slurries were allowed to ferment at room temperature under conditions of aeration, anaerobiosis and partial sterilisation with SO_2 for 16 weeks. Samples withdrawn daily and later weekly were shown by paper chromatography to

contain the following amino-acids: aspartic acid, glutamic acid, serine, glycine, threonine, alanine, arginine, lysine, γ -aminobutyric acid, tyrosine, proline, valine and leucines.

In anaerobic conditions serine and tyrosine disappeared within a week and threonine after 8 weeks with simultaneous appearance of α -aminobutyric acid in considerable quantity. The latter acid, present only in traces in the other 2 slurries, was possibly formed from threonine by micro-organisms. Under continuous aeration there was an apparent maximum at 3 days followed by a rapid loss of the amino-acids, some being present only in traces after 14 days. In the presence of SO_2 and absence of oxygen the amino-acids remained constant and increased slightly in the later stages.

The beneficial effects of excluding air and the presence of SO_2 are evident in maintaining the amino-acid content in silage.—A. Hepburn.

THALER, H. Die löslichen Kohlenhydrate der Kakaobohne. [Soluble carbohydrates of cocoa

beans.] *Naturwissenschaften*, 1954, 41, 432. [Deutsch. Forschungsanst. Lebensmittelchem., Munich.]

Paper chromatography of extracts of Arriba cocoa revealed the presence of 2 carbohydrates in addition to glucose, fructose and sucrose, one a trisaccharide, the other probably a tetrasaccharide. It is suggested that these are raffinose and stachyose. Traces of a pentose and a methylpentose were also detected. The same carbohydrates were also found in a sample of cracked beans from Accra, as well as another carbohydrate, possibly a trifructose anhydride.

It is pointed out that the presence of raffinose and stachyose implies that the normal estimation of "sucrose" in raw cocoa or its products does not give a true picture.

The Arriba sample contained much glucose but hardly any fructose and the Accra one very little of either. Further studies are in progress.

- CROSBY, M. W., FICKLE, B. E., ANDREASSEN, E. G., FENTON, F., HARRIS, K. W. and BURGAIN, A. M. Vitamin retention and palatability of certain fresh and frozen vegetables in large-

scale food service. *Cornell Agric. Exp. Stat. Bull.* No. 891, June 1953, pp. 47. [Ithaca, N.Y.]

The study was made in the cafeteria of the College of Home Economics, University of New York. Ascorbic acid, vitamin B₁ and riboflavin were estimated before and after bulk cooking of Brussels sprouts, cabbage, cauliflower, rutabagas, spinach, frozen broccoli, Lima beans and peas. They were cooked by steaming and by boiling in a steam-jacketed kettle or open pot. Such variables as the amount of salt or water and the length of cooking time were recorded. The length of time for which the cooked vegetables were kept hot before serving was investigated also.

The retention of vitamins in vegetables cooked by the same method was not always the same. When boiled in an open pot or steam-jacketed kettle, the vegetables retained over 50 per cent. of each of the vitamins. Most of the vegetables retained more vitamins when steamed than when boiled; though still acceptable, some vegetables cooked by steaming were not as palatable as when boiled.

When vegetables were kept hot in a dry-heat counter, a steam counter or a bain-marie there was no further loss of vitamin B₁ or riboflavin; but ascorbic acid continued to be destroyed, and palatability decreased.

Starting in cold water instead of boiling water did not affect vitamin retention. None of the vegetables showed a difference in vitamin B₁ or riboflavin retention whether cooked with or without salt; the same was true for ascorbic acid in all vegetables except cabbage, which retained more when the water was salted.—G. F. Garton.

- ROSENER, L. and KAN, H. A chromatographic-spectrophotometric method for determination of vitamin A in margarine. *J. Assoc. Off. Agric. Chem.*, 1954, **37**, 887-894. [Lab. Vitamin Technol., Chicago, Ill.]

The unsaponifiable fraction of 10 g. of the margarine was dissolved in light petroleum and passed through a column of alkali-treated alumina. The vitamin A was eluted with light petroleum containing increasing concentrations of ethyl ether, and the course of the vitamin A was followed in weak ultraviolet light. The spectrophotometric measurement was made in isopropanol at 325 mμ. Recovery of from 95 to 105 per cent. was obtained

when vitamin A was added to unfortified margarine and from 102 to 108 per cent. when carotene was added.—R. J. Ward.

WILKIE, J. B. and JONES, S. W. **Standardization of alumina adsorbents for vitamin A chromatography.** *J. Assoc. Off. Agric. Chem.* 1954, **37**, 880-887. [Food and Drug Admin., Dept. Health, Education and Welfare, Washington 25, D.C.]

A sample of 1 g. of the alumina in 5 ml. petrol was mixed with 0.5 mg. of the dye FD and C Yellow No. 4 in 1 ml. light petroleum, and transferred to a chromatographic tube of 12 mm. diameter. Suction was applied to the column until it was just dry and 25 ml. petrol was poured through. The entire filtrate was made to volume, and the amount of dye in the filtrate was measured at 438 m μ . in a spectrophotometer. The dye retention of several untreated and alkali-treated samples of alumina was estimated, and compared with their efficiency in the estimation of vitamin A in margarine. From the results obtained it appeared that a dye retention of from 20 to 50 per cent. provided an adequate working range of adsorbent activity.—R. J. Ward.

BURNASHEVA, S. A. **Kristallicheskie efiry vitamina A. [Crystalline esters of vitamin A.]** *Biokhimiya*, 1954, **19**, 246-256. [Inst. Biokhim. A. N. Bakha, Akad. Nauk SSSR, Moscow.]

Vitamin A concentrates containing from 76 to 78 per cent. of vitamin A were obtained by a process of molecular distillation, saponification, gradual freezing-out and repeated high-vacuum distillation. A complex ester of vitamin A and anthraquinone-carboxylic acid was obtained in crystalline form. Complex esters were formed also with acetic acid and β -naphthoic acid. The biological activity of the crystalline compound was 1,256,500 I.U. per g.—D. W. Taylor.

AMES, S. R. and HARRIS, P. L. **Identification of the so-called "lard factor" as vitamin A.** *Science*, 1954, **120**, 391-393. [Res. Labs., Distillation Products Indust., Div. Eastman Kodak Co., Rochester 3, N.Y.]

Freshly rendered lard was subjected to molecular distillation at 215° C. and 10⁻³ mm. mercury pressure. The first fraction, representing about 10 per cent. of the original lard, was removed and saponified and vitamin A was estimated in it by the Carr Price reaction. Eight samples of lard were examined, and contained from 5.5 to 28 "units" [probably U.S.P.U.] per g. distillate, representing from 0.5 to 2.5 "units" per g. original lard. When a lard distillate and a sample of the unsaponifiable matter from it were tested by the U.S.P. biological method, the potency of the original lard distillate was 5.01 \pm 1.18 "units"

per g. and of the unsaponifiable matter 62.5 \pm 9.9 "units" per g., compared with 6.18 and 135 "units" per g. by the Carr Price test. Positive identification of vitamin A in two distillates was made by applying the anhydrous HCl dehydration of Shantz *et al.* (Abst. 2012, Vol. 13).

MILLEN, J. W., WOOLLAM, D. H. M. and LAMMING, G. E. **Congenital hydrocephalus due to experimental hypovitaminosis A.** *Lancet*, 1954, **267**, 679-683. [Dept. Anat., Univ. Cambridge.]

Female rabbits were given a diet deficient in vitamin A for up to 38 weeks before mating and during pregnancy. Twelve litters from 11 dams were examined, 4 from dams fed on the deficient diet for from 16 to 21 weeks before mating. The 13 young from the latter group were stillborn or died within 24 hr. after birth. The young in the remaining 8 litters were removed when the dams were killed on the 29th day of pregnancy; the dams had been on the deficient diet for from 14 to 38 weeks before mating. Animals fed on the same diet with supplements of vitamin A were killed on the 29th day of gestation also. Coronal sections were cut through the heads of the young from deprived and non-deprived dams. Hydrocephalus was present in 47 of the total 51 young from the depleted dams. Estimation of vitamin A in the liver of the dams which were killed showed from 0 to 10 I.U. per g. The cause of hydrocephalus is obscure, but it is suggested that there may be an overproduction of cerebrospinal fluid and possibly also some constriction of the cerebral aqueduct.—I. M. Sharman.

1841

LAMMING, G. E., WOOLLAM, D. H. M. and MILLEN, J. W. **Hydrocephalus in young rabbits associated with maternal vitamin A deficiency.** *Brit. J. Nutrition*, 1954, **8**, 363-369. [Agric. Res. Council Unit Animal Reproduction, Huntingdon Rd., Cambridge.]

Rabbits from an inbred strain were fed on a pelleted diet without vitamin A or with a weekly supplement of 7500 μ g. vitamin A acetate. After 14 weeks all were mated. Nine litters were obtained from 8 females with incipient vitamin A deficiency and were compared with 9 litters obtained from 8 non-deprived females. The young from the non-deprived females received no vitamin A other than that obtained from the mother's milk. The young from the deprived females developed convulsions, paralysis and head retraction from 21 to 74 days after birth. After they had died their skulls were sectioned in the coronal plane, the brain remaining *in situ*. Similar sections were made from the young of the non-deprived females. Twenty-six of 35 young from does fed on the deficient diet had hydrocephalus with stenosis of the cerebral aqueduct, but such abnormalities were not seen in any of the young of the non-deprived females. The results suggest that the papilloedema and compression of the optic nerve observed in vitamin A deficiency may be a direct result of increased pressure in the subarachnoid space in the region of the optic foramen.

1842

MOURRIQUAND, G., ROLLET, J. and EDEL, V. Avitaminose A du rat et problèmes nutritionnels posés par la nécrophagie. [Vitamin A deficiency in the rat and nutritional problems set by cannibalism.] *C.R. Soc. Biol.*, 1954, **148**, 1260-1262.

During researches on the toxicity of naphthalene it was found that the ocular signs associated with deficiency of vitamin A were delayed in rats that had resorted to cannibalism. A rat given a diet deficient in the vitamin for 14 days devoured another rat in the same cage which had eaten the same diet for the same time. Signs of xerophthalmia, measured by the ophthalmoscope, were delayed for 3 months. The same observation was made on 3 other rats. Dietary deficiency is not, however, responsible for cannibalism, since rats fed on a complete mixed diet also eat their dead.

ROBERTSON, W. van B. and CROSS, V. Collagen formation in vitamin A-deficient rats. *J. Nutrition*, 1954, **54**, 81-86. [Div. Exp. Med., Coll. Med., Univ. Vermont, Burlington.]

Numerous weanling rats were given a basal diet deficient in vitamins A and C for 3 weeks, some only of them being given liberal doses of vitamin A or C or both. All were then injected subcutaneously with an extract of Irish moss to promote formation of new fibrous tissue, further rats being at the same time included in the groups given

vitamins A and C. Fourteen days after the injection of Irish moss extract the rats were killed, and collagen was estimated in the repair tissue round the site of injection. The concentration of collagen in the deficient rats was the same as in normal animals which had been injected with moss extract, and was not influenced by the administration of vitamin A or C. The results are at variance with the view that vitamin A deficiency produces deficiency of vitamin C in the rat as a secondary effect. [Data on the total amount of collagen formed, as opposed to its concentration, are not included.]—T. Moore.

1844

FORTNER, J. G. (with KOHEN, A. N.) Experimental studies of gallstone formation. *Surgery*, 1954, **36**, 932-940. [Div. Exp. Surg., Sloan-Kettering Inst., New York.]

The fat-free purified diet, described by Dam and Christensen as giving rise to gallstones in hamsters (*Acta pathol. microbiol. scand.*, 1952, **30**, 236; *Abst.* 4874, Vol. 23), was given to weanling Syrian hamsters with modifications of the vitamin A and D supplements. If vitamin A or vitamin D was omitted the incidence of gallstones rose. The effect of vitamin A deficiency was statistically significant; that of vitamin D deficiency was not but was considered highly suggestive. Gallstones were not found in hamsters receiving a normal laboratory diet, but on the purified diet even with vitamins A and D they occurred in 10 per cent. of the animals. The stones were composed mainly of crystalline cholesterol and were frequently embedded in a gelatinous mucoid mass in the lumen of the gallbladder. Attempts to discover the mechanism of gallstone formation are in progress.—A. M. Copping.

1845

ERICHSEN, S., HARBOE, A. and LINDBERG, W. An attempt to produce manifest toxoplasmosis in vitamin A deficient rats. *Nord. Vet.-Med.*, 1954, **6**, 791-794. [Vet. Coll. Norway, Oslo.] German and Norwegian summaries.

Weanling rats were given a diet low in vitamin A until, after 4 weeks, deficiency was shown by loss of weight or xerophthalmia. Half the animals were then given vitamin A at the rate of 2 I.U. daily, which was barely adequate for survival. The remainder were given 25 I.U. vitamin A daily, which sufficed for rapid growth. One week after treatment began, half the animals receiving each dose were injected subcutaneously with peritoneal exudate from mice infected with the R.H. strain of *Toxoplasma*. The animals were continued for 4 more weeks and were then killed. The differences between the groups during life and at autopsy depended on the amount of vitamin A given, and

N.A. and R., April 1955

not on the infection with *Toxoplasma*, which could not be found in any of the animals. Vitamin A deficiency did not, therefore, increase the liability to infection by *Toxoplasma*.—T. Moore.

GALLIGANI, G. Malattie della sfera genitale femminile e vitamina A. [Disorders of the female genital tract and vitamin A.] *Riv. Zootec.*, 1954, 27, 274-275.

It is considered that vitamin A can be given with advantage to cows that have infections of the epithelium of the genital tract leading to sterility.—E. M. Hume.

1847

BALAKHOVSKIĖ, S. D., VOSKRESENSKAYA, E. V. and FEDOROVA, V. N. Raspreделение ^{35}S v organakh i tkanyakh normal'nogo i A-avitaminizirovannogo organizma posle vnutribryushnogo vvedeniya mechen'nogo po sere metionina. [Distribution of ^{35}S in organs and tissues of the normal and vitamin-A-deficient organism after intraperitoneal injection of sulphur-labelled methionine.] *Dokl. Akad. Nauk. S.S.S.R.*, 1954, 97, 115-118. [Inst. Biokhim. A. N. Bakha, Akad. Nauk SSSR.]

The distribution of sulphur (^{35}S) in tissues of normal and vitamin-A-deficient rats was estimated at intervals after intraperitoneal injection of labelled methionine. After 48 hr. there was a significantly higher content of ^{35}S in the liver and kidneys of the deficient animals. Between 5 and 10 days after injection the values were much lower in both groups, and there was no significant difference between the groups. It is suggested that vitamin A deficiency may inhibit intracellular oxidation and excretion of sulphur.—D. W. Taylor.

1848

LEUTSKIĖ, K. M. and LYUBOVICH, E. N. O soderzhanii fosfatidov i nenasyshchennykh zhernykh kislot v svyazi s izmeneniem oksitel'nykh protsessov b tkanyakh krysa pri nedostatochnosti vitamina A. [Relation between phosphatide and unsaturated fatty acid content, and altered oxidation processes in the tissues of vitamin-A-deficient rats.] *Dokl. Akad. Nauk S.S.S.R.*, 1954, 96, 341-342. [Chernov. Gosud. Univ.]

Phosphatides and unsaturated fatty acids were estimated in the tissues of normal and vitamin-A-deficient white rats. The experiments lasted for from 2 to 2½ months, the initial weight of the animals being about 50 g. In the deficient rats, the phosphatide content of the kidneys, lungs and brain was significantly raised, by 91, 73 and 31 per cent., respectively, and the iodine value for the

fat in the liver, kidney and lungs was increased by 25, 14 and 17 per cent., respectively.

HIGH, E. G., SMITH, H. C. (JR.), TAYLOR, H. H. and WILSON, S. S. Antioxidant studies concerned with the metabolism of carotene and vitamin A. *J. Biol. Chem.*, 1954, 210, 681-686. [Lab. Biochem. Res., Prairie View Agric. and Mech. Coll., Tex.]

When albino rats deprived of vitamin A were given 33 μg . carotene in cottonseed oil daily for 25 days, 78.0 μg . were deposited in the liver and 16.0 in the kidneys. When 10 mg. 2:5-ditertiary butylhydroquinone were given with the same amount of carotene, the liver and kidneys had 45.0 and 14.5 μg .; with 10 mg. octylhydroquinone the amounts were 32.2 and 19.2 μg .; and with 10 mg. ditertiary butyl-4-hydroxyanisole 39.1 and 13.0 μg . respectively. When 13 μg . vitamin A were given for 20 days alone or with 10 mg. α -tocopheryl acetate, 10 mg. monotertiary butylhydroquinone or 10 mg. octylhydroquinone, the total amounts of vitamin A deposited in the liver and kidneys were, respectively, 47.5, 47.0, 46.1 and 46.4 μg . Young rats with low initial vitamin A reserves were given 33 μg . carotene alone or with 10 mg. 2:5-ditertiary butylhydroquinone or 10 mg. ditertiary butyl-4-hydroxyanisole and faeces were collected every 24 hr. for 4 days. The percentage of carotene excreted was 47.6, 46.8 and 52.4, respectively. When the supplements were given in rancid olive oil the percentage excretions were 31.5, 51.0 and 50.0, respectively.

All the anti-oxidants protected carotene from oxidative decomposition at 60° C. *in vitro*.

1851

MONTAGNA, W. Penetration and local effect of vitamin A on the skin of the guinea pig. *Proc. Soc. Exp. Biol. Med.*, 1954, 86, 668-672.

[Arnold Biol. Lab., Brown Univ., Providence, R.I.]

The penetration of vitamin A through the skin of guinea pigs was studied by clipping the hair from the backs and giving one topical application of a 0.5 per cent. solution of the vitamin in alcohol, chloroform, oleic acid, or linoleic acid, or of a preparation of the vitamin made up with petrolatum, zinc oxide and talcum. Specimens of skin were taken by biopsy 10 min. 1 hr. and 2 hr. later, and sometimes after 4 and 8 hr. Frozen sections were cut without fixation, and the penetration of the vitamin was studied by fluorescence microscopy. With the alcoholic solution the stratum corneum and the sebium in the pilosebaceous orifices exhibited the greenish-yellow fluorescence characteristic of vitamin A after 10 min., and after 1 hr. the fluorescence had reached the sebaceous glands. In chloroform the penetration was even more rapid, but in the other media it was much slower.

In order to study the behaviour of the vitamin dissolved in oleic or linoleic acid, an open aluminium tube, 0.6 cm. wide by 1.2 cm. deep, was attached to the back of the animal by means of methyl methacrylate and adhesive tape. The tube, filled with the solution under investigation, was sealed and left in contact with the skin for up to 12 days. In alcoholic solution the vitamin was applied to the skin twice daily. With vitamin A dissolved in the fatty acids there was hypertrophy of the skin, but the same change was produced by the acids alone. The vitamin dissolved in alcohol also caused hypertrophy, which with alcohol alone was slight. The fatty acids, with or without vitamin A, appeared to retard keratinisation, but vitamin A in alcohol did not. Even massive doses of vitamin A in alcohol did not impair the growth of hair.—T. Moore.

1852

ARNRICH, L. and MORGAN, A. F. The utilization of carotene by hypothyroid rats. *J. Nutrition*, 1954, 54, 107-119. [Dept. Home Econ., Univ. California, Berkeley.]

Young male rats depleted of vitamin A were fed on a diet deficient in vitamin A supplemented with 35 μ g. carotene daily. On attaining 200 g. weight the animals were divided into 4 groups, and those in 2 groups were made hypothyroid by inclusion in the diet of 0.15 per cent. thiouracil. One control and 1 hypothyroid group were next given 86 μ g. vitamin A daily for 7 weeks. The remaining 2 groups were given 440 μ g. carotene daily for the same period. After a subsequent depletion period of 2 weeks the rats were autopsied. Vitamin A in the livers of the hypothyroid rats given vitamin A averaged 495 \pm 27 μ g., the corresponding value for the control rats being 370 \pm 33 μ g. The groups given carotene had average values of

271 \pm 40 μ g. vitamin A for the hypothyroid animals and 106 \pm 23 μ g. for the controls.

In further tests male and female rats, both normal and hypothyroid, were given similar and twenty times the previous amounts of carotene. With the twenty-fold dose the amount of vitamin A stored in the liver was similar for the hypothyroid and control rats, average values ranging from 352 to 465 μ g. In another trial rats were allowed to build up uniform liver stores of vitamin A. In 12 of them steres averaged 335 μ g. for males and 513 μ g. for females. The remaining rats were grouped into sets of three of the same sex and bodyweight, each set including one control animal, one hypothyroid and one pair-weighted control, which was matched in bodyweight gain against a deficient animal by restricting food intake. They were killed after 10 weeks during which no carotene was given. Average values for vitamin A in the liver were then found to be greatly reduced, the respective values for the control, hypothyroid and pair-weighted control animals being 18, 57 and 50 μ g. for males and 47, 100 and 95 μ g. for females. The control male rats retained 5 per cent. of the initial amount after the depletion period, the hypothyroid animals retained 16 per cent. Corresponding values for females were 9 and 19 per cent. The calorie-restricted animals retained almost the same percentages as the hypothyroid rats.

1853

LAUGHLAND, D. H. and PHILLIPS, W. E. J. The effect of sodium bentonite administration on vitamin A metabolism in the rat. *Canad. J. Biochem. Physiol.*, 1954, 32, 593-599. [Chem. Div., Sci. Serv., Canada Dept. Agric., Ottawa.]

Sodium bentonite, an acid clay, has been recommended as a lubricant for the dies of machines used for the manufacture of diet pellets. It has been claimed that a harder and more attractive pellet results when 2 per cent. of the compound is included in the diet. It is reported now that inclusion of the compound severely limits the ability of rats deficient in vitamin A to store the vitamin. Six groups of albino rats were given a diet deficient in vitamin A. After 3 weeks vitamin A acetate was added to the diet of 5 of the groups at the rate of 10,000 I.U. vitamin A per kg. diet, and they received 0, 0.5, 1.0, 1.5 or 2.5 per cent. of sodium bentonite. After a further 3 weeks, vitamin A was estimated in the liver and the amount averaged 12 I.U. per liver for the rats not given vitamin A, and 181, 109, 47, 44 and 15 I.U., respectively, for the groups having bentonite in the order given above.

In a second, similar experiment the supplement of vitamin A was increased to 20,000 I.U. per kg. diet, and the animals were killed after 6 days.

N.A. and R., April 1955

The corresponding average content of vitamin A in the liver was then 8, 152, 61, 57, 28 and 7 I.U. When similar amounts of sodium bentonite were given to normal rats no significant change was found in the amount of vitamin A stored in the liver. In a further experiment 7 groups of rats were given for 14 days a diet deficient in vitamin A, but supplemented with 24 mg. β -carotene per kg., without sodium bentonite or with 0.5, 1.0, 1.5, 2.0 or 3.0 per cent. A seventh group received 3 per cent. Alphacel, a ground cellulose preparation providing bulk without energy value. The average content of vitamin A in the liver of the 7 groups as shown above was 622.5, 492.3, 495.2, 385.5, 445.0, 313.3 and 539.6 I.U., respectively. The weight of the liver per 100 g. bodyweight was significantly increased in all the groups receiving more than 0.5 per cent. sodium bentonite. The group having Alphacel also had a significantly higher liver weight. Storage of vitamin A was thus less in all groups given sodium bentonite than in those without it.—I. M. Sharman.

1854

LAUGHLAND, D. H. and PHILLIPS, W. E. J. **The adsorption of vitamin A by sodium bentonite.** *Canad. J. Biochem. Physiol.*, 1954, **32**, 610-620. [Chem. Div., Sci. Serv., Canada Dept. Agric., Ottawa.]

Sodium bentonite was added to solutions of vitamin A in Skellysolve B and allowed to stand in the dark; a blue adsorption complex was formed so that 17.50 μ mol. vitamin A alcohol were adsorbed by 1 g. bentonite from a solution containing 21.22 μ mol. of the vitamin. Sodium bentonite had a greater affinity for vitamin A alcohol than for the acetate or palmitate. In addition to the physical adsorption of the vitamin on sodium bentonite, spectrographic analysis of the resulting solutions revealed that a chemical change occurred in the vitamin A molecule, giving rise to anhydrovitamin A with an absorption maximum at 370 $m\mu$. When excess vitamin A had been removed with fresh Skellysolve B, the adsorbed product could be extracted with diethyl ether, but the blue colour was destroyed and a secondary reaction product was formed as an orange-coloured oil. Experiments were made with different proportions of vitamin A and sodium bentonite, the mixture being allowed to stand for varying times before removal of the supernatant fraction. From spectrographic results obtained with the reaction mixtures, equations were evolved from which it was possible to calculate the amount of vitamin A alcohol and anhydrovitamin A present at any time after the beginning of the reaction. Satisfactory agreement between calculated and observed values was obtained. The

compound extracted with ether had the characteristics of triene conjugation and an absorption maximum at about 290 $m\mu$.—I. M. Sharman.

BAKER, F. H., POPE, L. S. and MACVICAR, R. **The effect of vitamin A stores and carotene intake of beef cows on the vitamin A content of the liver and plasma of their calves.** *J. Animal Sci.*, 1954, **13**, 802-807. [Oklahoma Agric. Exp. Stat.]

Hereford cows in 4 groups of 5 were given a basal ration with no added carotene, or with 300 mg. carotene per head during lactation, or with 60 mg. during gestation, or with 60 mg. during gestation and 300 mg. during lactation. Values are presented for vitamin A and carotene in the liver and plasma of the cows 5 months before parturition, at parturition, and 3 months afterwards, and of the calves at birth and at 3 months of age, and for colostrum at parturition, and for milk after 1 week and 3 months.—R. J. Ward.

ROUSSEAU, J. E. (JR.), DEMBICZAK, C. M., DOLGE, K. L., EATON, H. D., BRALL, G. and MOORE, L. A. Relationship between plasma vitamin A and liver vitamin A in calves fed a vitamin A depletion ration and calves fed minimum levels of vitamin A or carotene. *J. Dairy Sci.*, 1954, **37**, 1376-1382. [Dept. Animal Indust., Storrs Agric. Exp. Stat., Conn.]

Calves were given a ration deficient in vitamin A until the blood plasma concentration had decreased to the desired value of 2.0 μg . per 100 ml., when they were slaughtered. Other calves were given the same ration until the blood plasma value had decreased to 10 μg . per 100 ml., when they were given 2, 4, 6, 8 or 10 μg . vitamin A, or 12, 18, 24, 30 or 36 μg . carotene, per lb. bodyweight daily for 142 days. Vitamin A was estimated in the plasma and liver at the time of slaughter, and the log of the value in μg . per 100 ml. plasma was plotted against the log of the value in μg . per 100 g. liver. In both the depleted group and the groups receiving vitamin A or carotene, a straight line relationship was found of the type $Y = a + bX$, where $Y = \log$ plasma concentration and $X = \log$ liver concentration. For the depleted group a was found to be 0.30 and b 0.2964; for the supplemented a was 0.50 and b 0.2846.—R. J. Ward.

1862

ELLMORE, M. F. and SHAW, J. C. The effect of feeding soybeans on blood plasma carotene and vitamin A of dairy calves. *J. Dairy Sci.*, 1954, **37**, 1269-1272. [Dairy Dept., Maryland Agric. Exp. Stat., College Park.]

Twenty-two calves, mainly Holsteins, about 3 months old, were fed on a deficient diet for from 50 to 80 days until the plasma vitamin A fell to about 4 μg . per cent. They were then assigned to one of 6 groups, 2 calves in each group being used as controls and 2 for test. For 2 groups the same 2 calves acted as controls. Test animals in groups 1, 2 and 3 were given a concentrate mixture containing 30 per cent. ground raw soya beans, the controls a mixture containing cottonseed oil, and both test animals and controls received, respectively, 32, 48 or 64 μg . carotene daily per lb. bodyweight. Group 4 were given 32 μg . carotene per lb. bodyweight daily; the test animals were given roasted soya beans and the controls were the same animals as for group 1. Group 5 all received the raw soya bean diet and 32 μg . carotene, the test calves having iodinated casein in addition. In group 6, 8 μg . vitamin A ester per lb. bodyweight daily was given instead of carotene; the diets were the same as for groups 1, 2 and 3. In groups 1 and 2 the soya beans depressed the mean plasma vitamin A value from 9.60 to 6.12 and

from 12.17 to 7.71 μg . per 100 ml., respectively. Calves in group 3 showed no significant depression of the plasma vitamin A. The roasted soya beans depressed plasma vitamin A from 9.60 to 4.75. There was no appreciable difference in the plasma values for group 5 but in group 6 the value was depressed from 8.54 to 5.05. The results show that, to allow a safety margin, a minimum of 64 μg . carotene per lb. bodyweight daily should be provided when soya beans constitute 30 per cent. of the ration.—I. M. Sharman.

1863

JACOBSON, N. L., ALLEN, R. S., BLAKE, J. T. and HOMMEYER, P. G. The effect of method of administration on the absorption and storage of vitamin A by dairy calves. *J. Nutrition*, 1954, **54**, 143-153. [Iowa Agric. Exp. Stat., Ames.]

Twenty-four dairy calves were reared on a diet without vitamin A until the concentration of the vitamin in the plasma was on the average 8 μg . per 100 ml. The animals were divided into 4 groups, each containing 5 Holsteins and one Brown Swiss. Vitamin A was then given twice weekly to each group at the rate of 10,500 μg . per 100 lb. bodyweight for 6 weeks. Calves in groups 1 and 2 were given the vitamin in skimmed milk from a nipple bottle. In group 1 the vitamin was dissolved in maize oil; in group 2 it was emulsified with Tween 80. The calves in groups 3 and 4 were given their supplement by capsule, the vitamin being dissolved in maize oil for group 3 and emulsified with Tween 80 for group 4. After the period with supplements each calf continued to receive the same deficient diet until the concentration of vitamin A in the blood plasma fell to an average for 2 successive weeks of 5 μg . per 100 ml. Carotenoids and vitamin A were estimated in venous blood specimens taken at weekly intervals. The estimations showed that the best absorption of vitamin A was by the calves given their supplement emulsified in milk, values of between 15 and 17 μg . vitamin A per 100 ml. plasma being obtained for the period between 2 and 6 weeks after the supplement began. Corresponding values for the other forms of supplement were about 13 μg . or less per 100 ml. The depletion times after the supplements were stopped showed that the animals given the vitamin emulsified in milk had the largest stores of vitamin A, the times for groups 1, 2, 3 and 4 being approximately 24, 43, 19 and 34 days, respectively. Possible causes for the good absorption with the aqueous dispersion of the vitamin are discussed.—I. M. Sharman.

DAVIDOV, R. and ERMAKOVA, M. Soderzhanie vitamina A v moloke. [Vitamin A content of N.A. and R., April 1955]

milk.] *Mol. Prom.*, 1954, 15, No. 6, 32.

[Timiryazev Acad. Agric., Moscow.]

Vitamin A in milk was estimated by the $SbCl_5$ method. Samples from an experimental farm contained from 175 to 300 $\mu g.$ per kg. in the autumn and from 27 to 50 in the spring. The lag in change of vitamin A content after transfer to summer or winter feeding is attributed to the building up or use of reserves. Enrichment of the diet with silage led to a substantial increase in vitamin A content, especially in the spring months. D. W. Taylor.

SHROFF, N. B., SAMPATH, S. R., ANANTAKRISHNAN, C. P. and SEN, K. C. Vitamin A in dairy products. 3. Heat stability of vitamin A in ghee. *Indian J. Dairy Sci.*, 1954, 7, 159-170. [Indian Dairy Res. Inst., Bangalore.]

Ghee was prepared from fresh buffalo and cow's milk by heating the separated cream to 115° C. until clarified. Samples were heated in an aluminium container to 125° C. for 4 hr., to 150° C. for 1 hr., to 175° C. for 15 min. and to 200° C. for 10 min. The tests were repeated in an iron container and in an aluminium container immersed in a glycerine bath. Vitamin A was estimated in the ghee initially and in samples taken at intervals during heating.

The higher the temperature the greater was the destruction of vitamin A, 11 per cent. being destroyed in buffalo ghee after heating for 1 hr. at 125° C. in an aluminium container, and 100 per cent. after 10 min. at 200° C. Corresponding values obtained with the iron container were variable, some showing smaller and others larger losses of vitamin A. Losses were distinctly less with the aluminium container immersed in glycerine, amounting to 7 per cent. after 1 hr. at 125° C. and 45 per cent. after 15 min. at 200° C.

In further tests ghee was fortified with vitamin A acetate so that the final concentrations of vitamin A were 50, 100, 200 and 300 I.U. per g. The fortified samples were heated alone and with 0.02 per cent. hydroquinone. Losses of vitamin A were generally relatively less the greater the amount added; thus, when fortified buffalo ghee was heated at 175° C. for 15 min. the loss was 95 per cent. when the vitamin A content was 50 I.U. per g., and 58 per cent. when it was 300. In the presence of hydroquinone the corresponding values were only 3 and 8 per cent. Vitamin A was less stable to heat in stored than in fresh ghee.

In other tests with cow's colostrum and milk fat it was found that more carotene than vitamin A was lost when samples were heated for up to 1 hr.—I. M. Sharman.

WECKEL, K. G. and CHICOYE, E. Factors responsible for the development of hay-like flavor in vitamin A fortified low-fat milk. *J. Dairy Sci.*, 1954, 37, 1346-1352. [Dept. Dairy and Food Indust., Univ. Wisconsin, Madison.]

When low-fat milk which had been fortified with 2000 I.U. vitamin A per quart was exposed in clear glass bottles for 2 min. to sunlight or at a distance of 12 in. from a 40-watt fluorescent lamp, a strong hay-like flavour developed in from 48 to 72 hr., but milk without added vitamin A did not develop any such flavour. Copper added in an amount of from 0.5 to 1.5 p.p.m. caused the development of oxidised flavour in about 72 hr. in both fortified and unfortified milk, and hay-like flavour in fortified milk after 120 hr. Addition of ascorbic acid delayed the changes. Butylated hydroxyanisole in an amount of 0.1 p.p.m. prevented the formation of both flavours, but 10 p.p.m. of nordihydroguaiaretic acid reduced the intensity only of the hay-like flavour.—R. J. Ward.

MITCHELL, H. L., BEAUCHENE, R. E. and SILKER, R. E. Stability of carotene in dehydrated alfalfa meal with effect of antioxidants, oil, and heat. *J. Agric. Food Chem.*, 1954, 2, 939-941. [Kansas Agric. Exp. Stat., Manhattan.]

A new anti-oxidant, NN'-diphenylhexamethylenediamine, was tested as preservative for carotene in stored alfalfa meal and found to be about as effective as the best of those previously reported in the literature. The diamine was applied by spraying different concentrations in solution in vegetable oil in a rotary mixer at the rates of 16, 32 and 80 lb. oil per ton meal. The greater the amount of diamine applied, the greater the protective effect, and the efficacy of any given amount was greatest in the heavily oiled meal. The efficacy was increased by heating the meal after application of the diamine. When 0.02 lb. of the anti-oxidant was applied in 80 lb. oil per ton meal, and the treated meal was heated, the percentage loss of carotene during storage was reduced from 54 in the untreated meal to 17.

KON, S. K. Vitamine A des invertébrés marins et métabolisme des caroténoïdes du plancton. [Vitamin A in marine invertebrates and the metabolism of carotenoids in plankton.] *Bull. Soc. Chim. biol.*, 1954, 36, 209-225. [Nat. Inst. Res. Dairying, Univ. Reading.]

Extensive results are presented or reviewed on the vitamin A and astaxanthin content of krill

and other marine invertebrates which provide food for whales. Of numerous species examined the krill, *Meganyctiphanes norvegica* and *Thysanessa raschii*, were found to be outstandingly rich in vitamin A, which was located mainly in the eyes. In tests with rats on 8 extracts obtained from krill the growth-promoting power was only from 38 to 81 per cent. of the potency measured by the $SbCl_3$ method. It seems probable, therefore, that the vitamin A in krill is an unfamiliar isomer. It is suggested that marine invertebrates may be able to convert astaxanthin to vitamin A.

OWEN, E. C. The carotene, carotenoid and chlorophyll contents of some Scottish seaweeds. *J. Sci. Food Agric.*, 1954, 5, 449-453. [Hannah Dairy Res. Inst., Kirkhill, Ayr.]

Specimens of certain species of red, green and brown algae were analysed for carotene, total carotenoids except fucoxanthin, and total chlorophylls. Carotenoids were extracted after alkaline digestion and separated chromatographically. Chlorophylls were extracted with methanol and estimated spectrophotometrically. Red and green algae resembled land plants in having less carotene than xanthophylls. The content of pigments varied considerably. The ratios between groups of pigments were more nearly constant, and are discussed in relation to the ratios found by other observers. It is concluded that in marine algae, as in land plants, the carotenoid content is related more closely to the content of chlorophylls than of total solids.—V. H. Booth.

THOMAS, J. W., OKAMOTO, M. and MOORE, L. A. The ulnar epiphyseal cartilage width in normal and rachitic calves and its use compared to other methods of detecting rickets. *J. Dairy Sci.*, 1954, 37, 1220-1226. [Dairy Husb. Res. Branch, Agric. Res. Serv., U.S. Dept. Agric., Beltsville, Md.]

The method of measuring radiographically the width of the ulnar epiphyseal cartilage in young calves is exactly described. Results are presented for groups of from 9 to 37 male and female Jersey and Holstein calves with pictures taken 9 times at intervals from birth to the age of 240 days, in order to show the process of gradual closure in normal animals. A similar series is given for 2

The intensely red fruits of *Shepherdia canadensis*, which are eaten in Alaska, were extracted with acetone. The pigments were transferred from acetone to light petroleum and chromatographed on calcium carbonate. The column was developed with light petroleum containing a trace of acetone. Nineteen zones were separately eluted and most of them rechromatographed on calcium hydroxide. Absorption curves for each pigment fraction were recorded on a Beckman spectrophotometer.

The main bulk of the carotenoids was made up of 4 pigments among which lycopene and lycopanthin acetate were identified with good probability. Several other pigments were described but not definitely identified. Among them were 3 xanthophyllic esters and 5 suspected carotenes.

VITAMIN D

groups of about 10 calves given a diet of dried beet pulp and grain with or without vitamin D. The values for plasma Ca, serum phosphatase and cartilage width were significantly different between the groups, sufficiently so to permit detection of rickets. The relative rate of bodyweight gain was not so valuable for the purpose. For satisfactory diagnosis of rickets, it is recommended that the value for one criterion should be determined twice with an interval to establish the rate of change.

EWING, D. T., SCHLABACH, T. D., POWELL, M. J., VAITKUS, J. W. and BIRD, O. D. Spectrophotometric determination of vitamins D in

presence of vitamin A. *Anal. Chem.*, 1954, **26**, 1406-1409. [Kedzie Chem. Lab., Michigan State Coll., East Lansing.]

Chromatography in two stages was used to get rid of interfering substances in samples of irradiated ergosterol in maize oil, and in mixtures of vitamins A and D, when the concentration of vitamin D was less than 50,000 U.S.P.U. per g. A column of Superfritrol was used to remove vitamin A, carotenoids, pigments, some sterols and irradiation products of ergosterol other than vitamin D. Activated alumina was used to remove unsaturated compounds of the squalene type, decomposition products of vitamin A and other residual impurities. Combinations of ether, hexane and 0.6 per cent. ethanol were used as solvents and eluents. Spectral absorption of the eluate dissolved in hexane was measured at 265 $m\mu$, and the readings were converted to U.S.P. units with a conversion factor of 87,000. Details are given for the preparation of the adsorbents. Results are shown for samples containing different mixtures of vitamins A and D tested by the present method and biologically. For only 5 of 110 samples did the two sets of results differ from one another by more than ± 20 per cent. The oil tested should not contain less than 4000 U.S.P.U. per g. or accuracy will be less.—E. M. Hume.

The experiments were made with Wistar albino rats given the rachitogenic diet of Steenbock and Black with added B vitamins and carotene.

Vol. 25, No. 2

The protein of the diet is not of optimum composition, as shown by the amino-acid make-up. Only those animals were used which showed rickets of grade 3 as assessed by measurements of the metaphyses in X-ray photographs. Controls were given vitamin D₂.

The measurement of ion exchange between bone and the supplying fluid and the nature of that exchange are discussed at some length. The first experimental work described is the measurement of radio-activity of "mineralised bone tissue" (bone from a cow boiled for 90 min. in a 3 per cent. solution of KOH in ethylene glycol; also called glycol-ash = glycol ash), ground and suspended in a solution of Na₂HPO₄ with some radio-active P. The rate of uptake of ³²P by the bone salt was fast at first and became very slow when only a small part of the solid phase could be in equilibrium with the solution. The more concentrated the solution, the sooner the exchange became stationary.

When bone from rachitic and normal rats was compared in the same way, no important difference was found, and none was found between fat-free dry bone powder from the shafts of rachitic and normal femur and tibia.

In the studies of the living animal, from 15 to 20 μ C. ³²P in saline were injected directly into the left femoral vein. The rats were decapitated after intervals of from 5 min. to 24 hr. and the blood was collected. Radio-activity was measured in the right femur and deproteinised blood. The rate of disappearance of ³²P from the blood, 90 per cent. in the first hr., 98 per cent. in 24 hr., was similar in normal and rachitic rats, but the rate of fixation of ³²P in the bone after the first hour was much higher in the normal than in the rachitic rat. The first fixation is therefore thought to be by ion exchange and the later by growth and new formation of bone.

When 3000 I.U. vitamin D₂ in 0.1 ml. olive oil were given to rachitic rats 72 hr. before injection of ³²P, and the rats were killed 60 min. later, the amount of ³²P in the femur was much increased, but there is no information about what happened later or about how much of the P was exchanged at the surface and how much built into the bone. Vitamin D given 5 hr. before injection of ³²P had no effect, nor had vitamin D at either time any effect on normal rats.

A second effect of giving vitamin D 72 hr. before injection of ³²P was to restore inorganic P in the plasma of rachitic rats to normal values. To study the change further, plasma proteins were removed in stages by different precipitants and plasma was also passed through a column of Amberlite 400 (Cl). The experiments showed that plasma inorganic P had more than one component so that, for instance, ³²P was almost entirely held by the Amberlite column but another, inactive,

fraction passed through. If the observation is confirmed, its significance for bone formation is still to be explained.—I. Leitch.

1878

BUCKLEY, G. F. and HARTROFT, W. S. **Effects of choline on cardiovascular lesions induced by feeding large doses of vitamin D.** *Amer. J. Clin. Nutr.*, 1954, 2, 396-404. [Banting and Best Dept. Med. Res., Univ. Toronto.] Spanish summary.

One hundred and sixteen male rats weighing from 120 to 150 g. were maintained on a diet low in choline for from 31 to 42 days. There were 10 groups of from 8 to 15 rats. Two groups received no supplement, 2 received 0.85 per cent. choline chloride in the diet, 3 groups received vitamin D₂ in the diet to provide from 15,000 to 20,000 I.U. daily, and 3 groups received both supplements. At the end of the experiment tissue was taken for histological examination from the heart, aorta, liver, kidneys, spleen and pancreas.

In the heart and aorta of the groups having the low-choline diet alone, sclerotic lesions occurred in from 25 to 60 per cent. The lesions were completely prevented by choline. Vitamin D₂ in the low-choline diet more than doubled the incidence of cardiovascular lesions. Choline suppressed the lesions of aortic sclerosis in the rats given vitamin D₂, and the heart lesions were few and slight. The histological picture of the lesions is described. Damage to the kidneys reflected that to the heart. In the liver of the choline-deficient rats, whether given vitamin D₂ or not, there were abnormal deposits of stainable fat, but there was no fibrosis or cirrhosis, probably because the time was too short. The possibility that the lesion in the kidneys caused by the choline deficiency is the primary one is discussed.

Use of choline to combat human atherosclerosis is not considered justified at present, but it is suggested that when very large doses of vitamin D are given therapeutically, lipotropic factors might be given also as a protection.—E. M. Hume.

1879

BRUNE, H. and EGER, W. **Vergleichende Studien an wachsenden Ratten über chemisch-analytische, histologische und röntgenologische Knochenveränderungen bei der Vitamin D₃-Hypervitaminose.** [Comparative studies on growing rats of the chemical, histological and radiographic changes in bone in vitamin D₃ excess.] *Arch. Tierernährung*, 1954, 4, Beihefte, No. 4, 221-239. [Inst. Tierphysiol., Univ. Göttingen.]

Four groups of 30 rats weighing about 50 g. were given a diet of oat flakes 10, fishmeal 1.5,

soya meal 1, and fodder yeast 0.5 parts. The Ca and P content was considered optimum. Vitamin A, 100 I.U., was given twice during the experiment. One group received no addition. Vitamin D₃ was given by mouth to 3 groups for 5 weeks; one group received 10,000 I.U. daily for one week, 15,000 I.U. daily for 2 weeks and 7500 daily for 2 weeks; 2 groups received 5000 I.U. daily for 1 week and 7500 for 4 weeks, and of these last 2 groups, one had the parathyroid glands removed. The heaviest and the lightest rat in each group were killed at the end of each week. The femur and tibia were investigated.

The rats given vitamin D increased little in weight. The content of total ash and of Ca and P in the tibia of rats given vitamin D decreased at first and then began to increase, but never reached the values for those not given vitamin D. Histological examination was made of the distal end of the femur metaphysis, and X-ray photographs were taken of the distal end of the tibia. These findings are related in detail to those of chemical analysis, and their significance is discussed at length. In the conditions of the experiment, parathyroid removal did not appear to affect the results.—E. M. Hume.

1880

LANDAUER, W. **The effect of estradiol benzoate and corn oil on bone structure of growing cockerels exposed to vitamin-D deficiency.** *Endocrinology*, 1954, 55, 686-695. [Storrs Agric. Exp. Stat., Univ. Connecticut, Storrs.]

Crossbred cockerels were reared to the age of 45 days on a complete diet. Groups of 5 or 6 birds were given a high-cereal, rachitogenic diet without vitamin D, which it was subsequently realised might have been somewhat deficient in vitamins A and E as well. The result is not, however, thought to have been affected. In addition, daily intramuscular injections were given of 500 or 2000 µg. oestradiol benzoate or of 0.25 or 1.0 ml. Mazola oil. One group had no addition. Of 2 other groups given a complete diet, one of 5 birds had 2000 µg. oestradiol benzoate daily, and one of 10 had no addition. The birds were killed after 30, 41 or 57 days. At the end of the experiment, in the birds on the rachitogenic diet alone, loss of muscle tone was so great that they could not stand upright and their wings dropped, but those given oestradiol or Mazola had normal muscle tone. Weight increase was greatest in those given the complete diet; addition of oestradiol somewhat depressed the performance. With the diet deficient in vitamin D there was almost no growth; addition of either dose of oestradiol or of Mazola increased it to about the same extent. There was considerable parathyroid enlargement in all the groups given the diet deficient in vitamin D, and the

effect was not modified significantly by the supplements. Ossification of the long bones was excessive with the complete diet and oestradiol. It was defective with the diet deficient in vitamin D, but less so with the supplements of oil or hormone; histological examination showed corresponding degrees of rachitic change.

It is concluded that oestradiol treatment corrected to some extent the failure of Ca absorption brought about by lack of vitamin D. It is accepted that fat has a certain antirachitic action.

COATES, M. E., HARRISON, G. F., HENRY, K. M. and KON, S. K. Der Vitamin-D-Gehalt von nach dem Scholl-Scheer-Steinheilverfahren bestrahlter Milch. [The vitamin D content of milk irradiated by the process of Scholl, Scheer and Steinheil.] *Milchwissenschaft*, 1954, 9, 258-261. [Dept. Nutrit., Nat. Inst. Res. Dairying, Univ. Reading.]

The absence of vitamin D from milk irradiated with ultraviolet light as in Frankfurt am Main was reported by Wagner (*Milchwissenschaft*, 1952, 7, 396). At the request of Professor Scheer, the

authors undertook to test a sample of milk specially prepared under the supervision of Professor Scheer and others. For convenience the milk was condensed and tinned. It was tested for vitamin D on chicks by measurement of the tarsal-metatarsal distance, and on rats by measuring the ash content of the femur and humerus, against the international standard. From the chick tests the value per litre was calculated to be 377 I.U. and from the rat tests 340. The similarity of the two results showed that vitamin D must be present entirely as vitamin D₂. The milk could not be tested before irradiation, but there could be no doubt that the process must have raised the potency at least 10 times.—E. M. Hume.

HORN, V., BOGUTH, W. and JAHN, U. Untersuchungen über den Vitamin-D-Gehalt ultraviolett (u. v.) bestrahlter Vollmilch. [Vitamin D content of whole milk irradiated with ultraviolet light.] *Arch. Tierernährung*, 1954, 4, Beihefte, No. 4, 214-220. [Vet. Physiol. Inst., Justus Liebig Hochschule, Giessen.]

Weanling rats 3 weeks old received for 16 days McCollum's rachitogenic diet No. 3143. The test dose was given daily for 14 days at the end of which an X-ray photograph was taken of the knee joint. The protective dose was taken as that amount which protected 8 out of 10 rats; it had been previously established with vitamin D₂ as 0.008 μ g. Irradiated "Zentra" milk from Frankfurt am Main was tested in doses of 1 and 2 ml., but afforded no protection, from which it was concluded that the milk contained less than 350 I.U. vitamin D per litre. Milk from Giessen was irradiated in the Steinheil apparatus used in Frankfurt; known amounts of vitamin D₂ were added to it and to untreated milk, but there was no significant difference in potency between the 2 samples of milk, which, it was concluded, contained less than 156 I.U. per litre. In a further experiment 1.5 ml. cream from irradiated and untreated milk gave no protection. When a suspension of ergosterol was irradiated in the Steinheil apparatus in the same way as milk, the concentration of ergosterol had to be raised to 5000 μ g. per litre before 1 ml. provided a protective dose, which corresponded with an activation of only 0.16 per cent. of the original ergosterol.

Irradiated milk is not considered suitable for feeding young animals liable to rickets.

KEENER, H. A. The effect of various factors on the vitamin D content of several common forages. *J. Dairy Sci.*, 1954, 37, 1337-1345. [Dept. Dairy Husb., New Hampshire Agric. Exp. Stat., Durham.]

Samples of mixed hay, soya bean hay, grass silage, maize silage, clover hay and timothy hay were harvested in two successive summers and stored with special precautions. Some of the material was irradiated with a mercury vapour quartz lamp after it had been dried and ground. The vitamin D potency was measured with rats by the method of the U.S. Pharmacopoeia XII against a curve of response. The values for the grass and clover hays in I.U. per lb. as fed ranged from 170 to 1724, and for the silages from 62 to 85, or from 193 to 282 if calculated on the hay equivalent basis. The value of 170 was for early cut, mow-cured hay, and of 1724 for a second cutting of mow-cured hay. Later cuts had

higher potencies than early cuts. Most field-cured hay increased in potency the longer it was left in the field up to 3 days. Some silages had higher potency when used than when first ensiled. When irradiated some samples attained their maximum potency within 5 min., others in 10 or 20; after the maximum was reached further irradiation induced a decrease. Samples differed in the maximum potency attainable. The content of both provitamin D and vitamin D increased with increasing maturity and with advance of the season. The mean value after irradiation for 4 samples of grass or clover, on a dry basis, was 150 for the first cutting and 384 for the second.

VITAMIN E

1886

EDISBURY, J. R., GILLOW, J. and TAYLOR, R. J. **The determination of total tocopherol.** *Analyst*, 1954, **79**, 617-623. [Unilever, Ltd., Port Sunlight, Cheshire.]

Samples that contained more than 40 μ g. tocopherol per g. were saponified directly with potash in the presence of gallic acid or pyrogallol; samples that contained less than that amount were extracted with ether and then saponified. Purification of the unsaponifiable residue was achieved by adsorption on alkaline alumina, followed by elution of vitamin A, carotenoids and probably some other contaminants with 36 per cent. diethyl ether in light petroleum, and of the tocopherol with chloroform. A correction was made for highly oxidised carotenoids which were eluted with the tocopherol. The chloroform solution containing the tocopherol was reduced to 0.5 ml.; 0.2 ml. of 0.2 per cent. ferric chloride and 0.5 ml. of 1 per cent. $\alpha\alpha'$ -dipyridyl, both in chloroform, were added and the mixture was allowed to stand for 5 min. The resulting pink complex was extracted with 3-6 ml. water and absorption at 520 $m\mu$. was measured in a spectrophotometer. The sensitivity of the test is claimed to be 5 times that of the original method of Emmerie and Engel.—R. J. Ward.

1887

DEACON, B. D. and WAMBLE, A. C. **Vitamin E analytical procedure for cottonseed and its products.** *J. Amer. Oil Chem. Soc.*, 1954, **31**, 284-287. [Cottonseed Products Res. Lab., Texas Eng. Exp. Stat., Texas Agric. and Mech. Coll. System, College Station.]

Solid cottonseed products were extracted in a Soxhlet for 4 hr. with *n*-hexane, the resulting oil was washed with alkali and a portion was evaporated and distilled in a molecular still at 230° C. and a pressure below 25 μ . A portion of the molecular distillate was analysed for total tocopherols by

the ferric chloride, $\alpha\alpha'$ -dipyridyl method. The γ -tocopherol was estimated by the *o*-dianisidine diazo reaction. The total tocopherol content per ton of cottonseed ranged between 105 and 158 g. The α -tocopherol content varied between 58.2 and 72.4 per cent., and the γ -tocopherol between 41.8 and 27.6 per cent., of the total tocopherol content. The 1952 crop of cottonseed had a mean content of 84.6 g. vitamin E per ton of seed compared with 69 for the 1951 crop. Methanol extraction of rolled and of cooked cottonseed meats gave oils containing 0.11 and 0.18 per cent. vitamin E, values which compared favourably with that of 0.12 per cent. for wheat germ oil.—R. J. Ward.

1888

LINDAHL, P. E. and KIHLESTRÖM, J. E. **A constituent of male sperm antagglutin related to vitamin E.** *Nature*, 1954, **174**, 600-601. [Inst. Zoophysiol. Univ. Upsala.]

An alcoholic solution of a substance isolated from sperm antagglutin, which is the name given to a protein obtained from the prostate gland and able to prevent the agglutination of sperm, had absorption maxima at about 290 and 310 $m\mu$., which were ascribed to vitamin E. After oxidation with nitric acid, absorption was seen at 405 $m\mu$., typical of the red oxidation product of α -tocopherol. When the extract was dissolved in *n*-hexane the absorption spectrum had no well defined maximum, and none appeared, even after the solvent was changed to ethanol.—T. Moore.

1889

FERGUSON, T. M., ATKINSON, R. L. and COUCH, J. R. **Relationship of vitamin E to embryonic development of avian eye.** *Proc. Soc. Exp. Biol. Med.*, 1954, **86**, 868-871. [Dept. Poultry Husb., Texas Agric. and Mech. Coll. System, College Station.]

Eggs were collected from mated turkey hens which had received a vegetable diet containing soya bean oilmeal and yellow maize; the eggs were incubated artificially. The embryos were removed at intervals from selected fertile eggs, and from all eggs in which the embryo died or failed to hatch after 29 days. Failure in the development of the lens, with cloudiness of the central portion, was seen in many of the embryos. Haemorrhage in the vitreous humour and oedematous areas on the neck and feet occurred also. The embryos were undersized, and many died between the 24th and 28th days of incubation. Supplements of α -tocopheryl acetate given to the hens prevented the abnormalities. Fish solubles or dried whey or combinations of the two gave no protection. By chemical methods the egg yolks from turkeys given tocopherol were found to contain 3-6 times as much tocopherol as those from birds that received only the vegetable diet.

TEDESCHI, G. G. and DE CICCO, A. Distrofia muscolare conseguente alla somministrazione di succinato di o-cresolo. [Muscular dystrophy after administration of o-cresol succinate.]

Ricerche sulla azione antivitaminica E del meta- e para-cresolo e degli xilenoli. [Action of meta- and para-cresols and xyleneols antagonistic to vitamin E.] *Quad. Nutrizione*, 1952, **12**, 521-526; 1953, **13**, 166-173. [Ist. Fisiol. Gen., Univ. Rome.]

Of 46 rats weighing about 80 g., 2 groups of 8 were given a diet without vitamin E but otherwise complete, containing, per cent., casein 25, butter 9 and cod liver oil 2. One of the 2 groups received every 8 days a subcutaneous injection of 25 mg. o-cresol succinate. Three other groups received a diet deficient in vitamin E and similar to the first but low in protein, containing only 5 per cent. casein; one group of 8 had no addition, one of 16 received o-cresol as just described, and one of 6 received a subcutaneous injection of 10 mg. α -tocopherol every 8 days. The experiment lasted 45 days, and rats were killed at intervals after 15 days for histological examination of the hind-leg muscles. In the groups given a complete diet except for vitamin E, or a low-protein diet with vitamin E, signs of muscular dystrophy were apparent by the end of 45 days. In the rats given a low-protein diet without vitamin E, signs of muscular dystrophy had appeared by the 35th day and were severe by the 45th day. In the groups deprived of vitamin E and given o-cresol the signs were present by the 15th day and progressed in severity, which was greatest with the low-protein diet.

Female rats which had had a litter were maintained on a diet, per head daily, of boiled pasta, 5 ml. milk, 5 g. horseflesh, and cabbage or lettuce leaf. They received a single intramuscular injection of the test substance as the acetate dissolved in olive oil just before mating. With 25 or 50 mg. m-cresol acetate normal litters were born and reared. With 25 or 50 mg. p-cresol acetate the results were variable. Some rats showed immediate signs of intoxication; a small number reared litters. Simultaneous administration of 10 mg. α -tocopherol permitted the birth and rearing of normal young, but did not prevent the early signs of toxicity. With 50 mg. of 2-hydroxy-1:4-dimethylbenzene acetate the rats were all killed about the 17th day and showed placentas that were small, haemorrhagic and necrotic, and embryos that were in an advanced state of autolysis. With 50 mg. of 5 other hydroxydimethylbenzene acetates normal young were born and reared.

MARTIUS, C. and STRUFE, R. Phyllochinoreduktase. Vorläufige Mitteilung. [Phylloquinone reductase. Preliminary note.]

MARTIUS, C. Die Stellung des Phyllochinons (Vitamin K₁) in der Atmungskette. Vorläufige Mitteilung. [Position of phylloquinone (vitamin K₁) in the respiratory chain. Preliminary note.] *Biochem. Ztschr.*, 1954, **326**, 24-25; 26-27. [Physiol. Chem. Inst., Univ. Würzburg.]

1. The reduction of phylloquinone (vitamin K₁) by an enzyme preparation from liver mitochondria was investigated. The reductase was not highly specific and reduced quinones other than vitamin K₁. Vitamin K₁, on the other hand, appeared to be the only quinone concerned in respiratory phosphorylation. Reduction of vitamin K₁ was inhibited by dicoumarol, by thyroxine and by *p*-chloromercuribenzoic acid. The effect of thyroxine was greater in acid than in alkaline medium, that of *p*-chloromercuribenzoic acid was less in acid medium.

2. Because of the pyridine nucleotide associated with the reductase for vitamin K₁, further studies were made of the role of the vitamin in the respira-

tory enzyme chain with preparations of cytochrome from heart muscle. It seemed that vitamin K₁ was directly concerned in the formation of cytochrome *b*, and a possible scheme for the oxidation system is suggested.—A. M. Copping.

1898
JAQUES, L. B., MILLAR, G. J. and SPINKS, J. W. T. The metabolism of the K-vitamins. *Schweiz. med. Wochenschr.*, 1954, **84**, 792-796. [Dept. Physiol., Univ. Saskatchewan, Saskatoon.] German summary.

Studies of the mode of absorption of K vitamins made in rats receiving vitamins K₁ and K₂ labelled with ¹⁴C are summarised and discussed together with investigations of prothrombin time in dogs in which the bile was diverted from the intestine. Diversion of bile reduced the absorption of vitamin K₁ but had little effect on that of vitamin K₂. Both bile and pancreatic juice were required for the efficient absorption of vitamin K₁. Vitamin K₁ and K₂ were both excreted in the urine; they were not fixed in the liver or any other specific tissue. Considerable rearrangement of the vitamin K molecule seemed to occur during absorption. The deficiency of proconvertin and Ac-globulin in dogs with diverted bile was remedied by both forms of vitamin K. The deficiency of prothrombin was less readily repaired.—A. M. Copping.

1899
VAN KOETSVELD, E. E. and ONRUST, H. Een beschouwing over omzettingmogelijkheden van vitamine K₃ in voedingspreparaten. [Survey of the possible reactions of vitamin K₃ in foods.] *Chem. Weekblad*, 1952, **48**, No. 2, 22-24. [Netherlands Inst. Volksvoeding, Amsterdam.]

The chemical reaction between vitamin K₃, 2-methyl-1:4-naphthoquinone, and amino-acids is discussed. When vitamin K₃ was added to egg white it was almost all destroyed during storage for from 3 to 7 weeks, but with lactose or coconut fat little or no destruction occurred. Estimation was made by colorimetric and polarographic methods. The probable loss of vitamin K₃ from preparations for animal feeding is considered in relation to the findings.—A. M. Copping.

vitamins with a new criterion. 3. Estimation of three amino-acids and three vitamins.] *Arch. Sci. biol., Bologna*, 1954, **38**, 437-448. [Inst. Igiene Microbiol., Univ. Pavia.]

For previous parts see Abst. 2991, Vol. 24.

Strains of *Bacterium coli* were selected as having individual needs of certain metabolites. They were grown on 4 large plates of agar containing a basal culture medium and 4 graded concentrations of the essential metabolite under investigation. The 4 plates and 4 control plates without the metabolite were inoculated with a standard, very dilute suspension of the test organism. After 48 hours' incubation the diameter of from 60 to 100 colonies was measured. When the logarithm of the values for the mean diameter of the colonies was plotted against that of the values for the concentration of the metabolite a straight line was obtained which could be used to estimate the metabolite. Graphs are given of the results thus obtained with methionine, leucine and lysine, and for nicotinic acid, Ca pantothenate and vitamin B₁. The results are treated statistically.—E. M. Hume.

DE WATTEVILLE, H., JÜRGENS, R. and PFALTZ, H. (with SCHENKER, N. P., FUST, B., BORTH, R., PELEMON, B. and LUNENFELD, B.) Einfluss von Vitaminmangel auf Fruchtbarkeit, Schwangerschaft und Nachkommen. [Effect of vitamin deficiency on fertility, pregnancy and offspring.] *Schweiz. med. Wochenschr.*, 1954, 84, 875-883. [Clin. Gynéc. Obstét., Univ. Geneva.] English and French summaries.

For 13 days before pairing, adult female Wistar strain rats, 2600 in all, were fed on a diet containing, per cent., extracted casein 26, rice starch 56, oxidised coconut oil 13 and salts 5, with a daily supplement of B vitamins, and a weekly supplement of fat-soluble vitamins and choline chloride, the vitamins being in amounts 10 times those established as sufficient. Vitamin B₁, B₆ and A, pantothenic acid and riboflavin were withheld

singly. The experiments were of 4 types, the vitamin being withheld from pairing or before, from 13 days after pairing, from parturition, or not at all. In all groups some rats were killed every 2 days for histological investigation and autopsy. Normal males were used.

When the time of deprivation before pairing was 35 days, rats deprived of any of the vitamins were sterile. When it was 28 days, all were sterile except those deprived of vitamin A; when it was 13 days, from 17 to 40 per cent. of the rats deprived of the individual vitamins became pregnant. The course of pregnancy was followed by daily weighing. Weight curves are shown for those that eventually gave birth to litters and for those that did not. [No numbers are given.] Examination of the embryos from females killed between the 16th and 20th day of pregnancy showed haemorrhages in the head, and oedema of the head and body, in rats deprived of vitamin B₁; occurrence of haemorrhages was not, however, specific. With deprivation of riboflavin, abnormalities and monsters were frequent; rats deprived 13 days after mating usually had living young with malformation of the jaw and face. Young of deprived rats of vitamin B₆ or pantothenic acid had haemorrhages and oedema, syndactyly and club foot. With vitamin A deficiency the young had no eyes or rudimentary ones. With all deficiencies, the number of young and degree of damage depended on the duration of the mother's deprivation. The mean birthweight of full-term young decreased with the severity of the deprivation from 5.0 g. when all the vitamins were given. It was lowest at 3.4 g. with rats deprived of vitamin B₁ from 13 days before mating till parturition. The young from mothers deprived of vitamin A succumbed to infection with *Salmonella typhimurium* much more quickly than young from normally fed rats. (See also Title 320, Vol. 25.)—E. M. Hume.

SCHREIBER, M. and ELVEHJEM, C. A. The influence of flavonoid compounds on the nasal excretion of a red pigment by rats subjected to stress conditions. *J. Nutrition*, 1954, 54, 257-270. [Dept. Biochem., Coll. Agric., Univ. Wisconsin, Madison.]

Weanling albino rats given a complete diet or a diet lacking vitamin B₁, riboflavin, nicotinic acid, pyridoxine, pantothenic acid or choline were housed at a relative humidity of 90 per cent. and a temperature of from 24° to 26° C. These conditions had been found to induce nasal excretion of a red pigment in vitamin-deficient rats (Abst. 4107, Vol. 23). If a mixture of rutin, quercetin and quercitrin was included in diets lacking riboflavin or pyridoxine the appearance of the red pigment was prevented and consumption of water rose.

Restriction of water intake with a complete diet could cause the red nasal discharge and the incorporation of rutin or quercetin in the diet was again protective. Reduction of the relative humidity to 70 per cent. also prevented the discharge.

A series of experiments was made with deficiency of the several B vitamins and addition of flavonoid substances. The greatest protection was obtained with quercetin and rutin. Quercitrin and naringin were less effective and hesperetin, hesperidin, naringenin and hesperidin-methylchalcone had little effect. A large excess of menadione was protective; penicillin, streptomycin, aureomycin, salicylic acid and ascorbic acid were inactive. The requirement of flavonoid compounds in adverse physical conditions and in vitamin deficiencies is discussed.—A. M. Copping.

1906

HUNT, C. H., HERSHBERGER, T. V., BENTLEY, O. G. and MOXON, A. L. Effect of certain adsorbents and mineral mixtures on the availability of riboflavin and other B-vitamins in rations. *Ohio Agric. Exp. Stat. Res. Bull.* No. 748, August 1954, pp. 15. [Wooster, Ohio.]

Studies were made with rats of the availability of riboflavin, pantothenic acid and nicotinic acid adsorbed on fillers or mineral mixtures before addition to stock rations; B vitamins were estimated also by microbiological methods.

Riboflavin mixed with bonemeal, limestone, dicalcium phosphate and one brand of fuller's earth was available for rats and micro-organisms. If it was mixed with two other samples of fuller's earth, bone black or norite A, its availability was much less. Some fillers interfered with the availability of riboflavin in natural feeds such as alfalfa. Pantothenic acid and nicotinic acid were tested with two mineral mixtures. In one the vitamins were available and in the other their activity was considerably reduced. Pantothenic acid was lost also from rations stored at temperatures permitting the development of rancidity. The findings suggested that careful tests were needed to find suitable mixtures for feed supplements.—A. M. Copping.

SHRIMPTON, D. H. The utilisation of the intestinally synthesised riboflavin and vitamin B₁₂ by poultry. *10th World's Poultry Congr. Sect. Papers*, Edinburgh, 1954, 161-163. [Rowett Res. Inst., Bucksburn, Aberdeenshire.]

1908

HOLLIS, L., CHAPPEL, C. F., MACVICAR, R. and WHITEHAIR, C. K. Effect of ration on vitamin synthesis in rumen of sheep. *J. Animal Sci.*,

1954, 13, 732-738. [Dept. Agric. Chem. Res., Oklahoma Agric. Exp. Stat.]

Yearling wether lambs were fed for 30 days before slaughter on 8 different rations, and riboflavin, nicotinic acid and pantothenic acid were estimated in the rumen contents by microbiological methods. When prairie hay was given alone there was little synthesis of the vitamins in the rumen. Synthesis was increased when maize and soya bean meal were given with the hay. Additional nitrogen in the form of urea also increased the amount of synthesis. Replacement of prairie hay by maize cobs, sorghum silage or alfalfa hay did not cause much change in vitamin synthesis. Addition of alfalfa ash to the maize cob ration increased the amount of all 3 vitamins in the rumen.

1909

TERLIZZI, L. Avitaminosi "B" e dieta proteica esclusiva di origine vegetale o animale. [Deficiency of vitamin "B" and a diet exclusively of protein of animal or vegetable origin.] Avitaminosi "B" e dieta proteica esclusiva mista. [Deficiency of vitamin "B" and a diet exclusively of protein of mixed origin.] *Bol. Soc. ital. Biol. sper.*, 1954, 30, 315-317; 317-318. [Ist. Fisiol., Univ. Bari.]

Four young male rats weighing about 140 g. were maintained on a diet of, per cent., wheat gluten 91 and ovalbumin 9; 3 others received a diet of, per cent., purified casein 35, ovalbumin 10 and ox fibrin 55; another 2 received a diet of purified casein 16, purified dextrin 40, cane sugar 20, olive oil 15, agar 2 and salts 2 parts. All 3 groups were given salts and fat-soluble vitamins but no B vitamins. The rats given only animal protein lost weight and died within 56 days. All except one animal in the other groups made some growth. Those having the mixed diet lived about 100 days and those having the vegetable protein diet lived about 150. Signs of deficiency were muscular inco-ordination and spasticity.

In a similar experiment, the protein diet contained wheat gluten, ox fibrin and purified casein. Of 4 rats given the diet, 3 lost weight and died in less than 100 days. The fourth increased in weight to some extent and survived as long as 2 rats given the same mixed diet as in the first experiment; all 3 died after between 100 and 150 days.

WAHLSTROM, R. C. The effect of penicillin and B-vitamins on the growth of pigs fed different levels of protein. *J. Animal Sci.*, 1954, 13, 918-926. [Dept. Animal Husb., S. Dakota Agric. Exp. Stat.]

Growth from weaning to 200 lb. was studied in pigs receiving from 10 to 18 per cent. of protein in

N.A. and R., April 1955

a basal diet of maize, soya bean oilmeal and digester tankage, with or without supplements of B vitamins and penicillin. A significant increase in rate of gain with all protein intakes occurred when penicillin or a mixture of riboflavin, nicotinic acid, pantothenic acid, vitamin B₁₂ and choline was added to the diet. The rations containing 10 per cent. protein appeared to be limited by their content of B vitamins, and more than 12 per cent. protein was desirable for satisfactory growth up to 100 lb. weight. Carcase measurements suggested that a larger proportion of the meat was lean in pigs given B vitamin supplements or high-protein diets than in those given less protein. Diets containing medium amounts of protein with supplements of vitamins, minerals and penicillin appeared to be most suitable for economic pig production.—A. M. Copping.

1911

HENSON, J. N., BEESON, W. M. and PERRY, T. W. Vitamin, amino acid, and antibiotic supplementation of corn-meat by-product rations for swine. *J. Animal Sci.*, 1954, **13**, 885-898. [Dept. Animal Husbandry, Purdue Univ. Agric. Exp. Stat., Lafayette, Ind.]

Pigs receiving a basal ration of maize, mineral mixture, alfalfa meal and meat tankage were given supplements of riboflavin, calcium pantothenate and nicotinic acid, with or without vitamin B₁₂ and terramycin. Those having the three B vitamins showed no improvement in response over those having no supplement. With the addition of terramycin and vitamin B₁₂ there was improvement in feed utilisation and weight gain. In a second trial vitamin B₁₂ alone was less beneficial than riboflavin, pantothenic acid and nicotinic acid. Terramycin alone or vitamin B₁₂ alone gave good weight gains but allowed signs of pantothenic acid deficiency to develop. In a third trial supplements of lysine, methionine and tryptophan were given, and the results indicated that tryptophan in the maize and tankage ration was inadequate. With a diet of maize and meat scraps tryptophan was again the most important amino acid lacking.—A. M. Copping.

SMITH, Q. T. and ALLEN, R. S. B-vitamin levels in the blood of young dairy calves fed a milk replacement diet with and without aureomycin. *J. Dairy Sci.*, 1954, **37**, 1190-1197. [Dept. Chem., Iowa State Coll., Ames.]

Vitamin B₁, riboflavin, pantothenic acid, nicotinic acid, and vitamin B₁₂ were estimated in venous blood of 10 male and 10 female Holstein calves 4 days old. Individual values varied widely; no significant difference was found between the sexes.

Eight four-day-old Holstein calves, 4 of each sex, were fed on a milk replacement diet, primarily of dried whey reconstituted with water, for 7 weeks. Cereals, minerals and hay were then given. Whole milk was included during the first 2 weeks. To 4 of them aureomycin was supplied by mouth at the rate of 40 mg. daily for 7 weeks and then 80 mg. up to 12 weeks. Four received no aureomycin. The vitamins enumerated above were estimated in venous blood samples taken at the beginning and after 1, 2, 4, 8 and 12 weeks. Aureomycin had no significant effect; there was no apparent difference between the sexes.

VITAMIN B₁ (ANEURIN, THIAMINE)

logical estimation of vitamin B₁ in blood with a mutant of *Bacterium coli*.] *Chem. Weekblad*, 1954, **50**, No. 2, 18. [Lab. Physiol. Chem., Univ. Amsterdam.]

A microbiological method is described for estimating vitamin B₁ in 0.2 ml. blood with a mutant of *Bacterium coli* in a simple glucose and ammonium sulphate medium. Up to 100 µg. vitamin B₁ per ml. whole blood could be satisfactorily measured.—A. M. Copping.

1917

CASTER, W. O. and MICKELSEN, O. **Thiamine-pyrimin assay. Factors influencing the yeast fermentation methods for thiamine and pyrimin.** *J. Agric. Food Chem.*, 1954, **2**, 1073-1076. [Lab. Physiol. Hyg., Univ. Minnesota, Minneapolis.]

In the yeast fermentation method for estimating vitamin B₁ and its metabolite pyrimin, potential sources of error were the amount of peroxide used in the sulphiting stage, the adequacy of shaking, and the presence of 4-methyl-5- β -hydroxyethyl-thiazole. There was interference also in certain foods from mixtures of active pyrimidines of different stability, and changes in vitamin B₁ and non-vitamin B₁ activity during the fermentation period. Sources of difference between different laboratories are discussed, and it is suggested that new limitations in the A.O.A.C. method for estimating vitamin B₁ will increase the reliability of the method.

DE RENZO, E. C., OLESON, J. J., HUTCHINGS, B. L. and WILLIAMS, J. H. **Vitamin B₁ activity of disulfide forms of thiamine.** *J. Nutrition*, 1954, **54**, 133-141. [Chem. Biol. Res. Sect., Lederle Labs. Div., Amer. Cyanamid Co., Pearl River, N.Y.]

Allithiamine and propylallithiamine, which are disulphide forms of thiamine, were tested with rats and chicks and gave a growth response equivalent to that of thiamine when the compounds were injected. When they were included in the diet the disulphide forms tended to give a greater growth response than thiamine. The thiamine content of the liver was slightly higher in rats receiving allithiamine than in those given the equivalent amount of thiamine. Allithiamine was antagonised by oxythiamine in the same way as thiamine.

Tests on 4 healthy men showed that allithiamine given by mouth produced a greater excretion of thiamine in the urine than equivalent amounts of thiamine.—A. M. Copping.

DAGLIANTI, A. **L'esame elettrocardiografico nel colombo. Contributo di tecnica. [Electrocardiographic examination of the pigeon. Technique.]** Contributo alla conoscenza del quadro elettrocardiografico del colombo beriberico per dieta orizanicca. [Electrocardiogram of the pigeon with beriberi from a rice diet.] *Bol. Soc. ital. Biol. sper.*, 1954, **30**, 82-83; 84-86. [Ist. Fisiol., Univ. Rome.]

A wooden box is described in which a pigeon could be confined with the possibility of only a very little movement, and the bird could become accustomed to remain quite still. The electrodes could then be attached to the bird, and satisfactory readings with the electrocardiograph were obtained.

Fifteen pigeons weighing from 350 to 450 g. were maintained for a month on a diet of maize and sunflower seed, and electrocardiograms were recorded daily with the apparatus described above. The diet was then changed to polished rice and the observations were continued until signs of beriberi appeared, usually after 16 or 17 days. The birds were then cured with vitamin B₁. In normal birds the rate of the heart beat was from 140 to 200 a minute; as beriberi developed it fell to from 90 to 120. The electrocardiograms showed no significant changes. Tracings are shown.

E. M. Huine.

1921

LA GRUTTA, G. and CILENTO, A. **Azione della vitamina B₁₂ sul beri-beri sperimentale del colombo. [Effect of vitamin B₁₂ on experimental beriberi in pigeons.]** *Bol. Soc. ital. Biol. sper.*, 1954, **30**, 51-54. [Ist. Fisiol., Univ. Palermo.]

Eight young pigeons weighing about 360 g. were given a diet of polished rice till signs of beriberi appeared. The amount of rice consumed was recorded, and the beriberi quotient of Amantea (Abst. 4092, Vol. 3) was calculated. The birds were then cured with a single injection of 5 mg. vitamin B₁₂, and fed on maize until the weight lost was regained. The experiment was then repeated with a daily intramuscular injection of 50 μ g. vitamin B₁₂, and again, after a second cure, without the vitamin. There was no significant difference between the 3 sets of results.—E. M. Huine.

DE LA FUENTE, G. and DÍAZ-CADAVEIRO, R. Co-carboxylase activity of thiamine phosphoric esters. *Nature*, 1954, 174, 1014. [Dept. Bioquím., Inst. Español Fisiol. Bioquím., Fac. Farm., Ciudad Univ., Madrid.]

Mono-, di- and triphosphoric esters of vitamin B₁ were separated by paper chromatography with *n*-propanol, water and 1 *M* acetate buffer at pH 5. Their separate co-carboxylase activities were measured in the presence of pure apocarboxylase prepared by the method of Green *et al.* (Abst. 1016, Vol. 11). The monophosphoric ester showed no activity in concentrations of from 0.025 to 0.13 μ mol. per ml. The diphosphoric ester liberated CO₂ at the rate of 2.3×10^3 μ l. per hr. in a concentration of 0.04 μ mol. per ml. The triphosphoric ester was inactive in concentrations of from 0.005 to 0.02 μ mol. per ml.—A. M. Copping.

ONRUST, H. De functie van thiamine pyrophosfaat bij de oxydatieve decarboxylering van pyrodruienzuur in dierlijk weefsel. [The function of vitamin B₁ pyrophosphate in the oxidative decarboxylation of pyruvic acid in animal tissues.] *Thesis, Univ. Amsterdam*, 1953, pp. 63. [Lab. Physiol. Chem., Univ. Amsterdam.] English summary.

In studying the mode of action of vitamin B₁ pyrophosphate as coenzyme in decarboxylation and in the oxidation of pyruvate in animal tissue, methods of preparing and estimating vitamin B₁ pyrophosphate were elaborated. Oxythiamine, oxythiamine triphosphate, pyrithiamine triphosphate and *p*-chloromercuribenzoic acid were prepared as inhibitors. All of them inhibited the decarboxylation of pyruvic acid by dehydrogenase prepared from pigeon breast muscle. The inhibition was more complete with oxythiamine triphosphate than with pyrithiamine triphosphate. With both the enzyme system was re-activated by dried brewer's yeast, which provided a carboxylase without oxidising capacity. Inhibition by *p*-chloromercuribenzoic acid was overcome by substances such as glutathione and thiomalic acid which contain active sulphhydryl groups. Addition of excess vitamin B₁ pyrophosphate did not re-activate the system when sulphhydryl groups were lacking, which was taken as evidence that the essential sulphhydryl groups of the carboxylase system were not derived from vitamin B₁ pyrophosphate. From discussion of the findings it is concluded that vitamin B₁ pyrophosphate has no oxidative function in the oxidative decarboxylation of pyruvate in animal tissue but is concerned primarily with the decarboxylation process.

NAIDOO, D. and PRATT, O. E. The activity and localisation of adenosine 5'-phosphatase in the thiamine deficient chicken brain. *Biochem. biophys. Acta*, 1954, 15, 291-292. [Inst. Psychiat., Univ. London, Maudsley Hosp.]

Adenosine 5'-phosphatase activity was studied histologically, and estimated as described previously (*Enzymologia*, 1954, 16, 289), in brains from normal chicks and chicks deprived of vitamin B₁. In the optic tectum and cerebral hemisphere from deprived chicks the fibres failed to stain, but the staining of the nuclei was strongly maintained. The phosphatase activity of the brains of normal chicks lay within the range from 18.1 to 20.6 "units"; that of deficient birds was from 22.7 to 26.0 "units". The findings suggested that adenosine 5'-phosphatase is in some way involved in the reaction of brain tissue to vitamin B₁ deficiency.—A. M. Copping.

1925

KRING, J. P. and WILLIAMS, J. N. (JR.) Dietary conditions affecting oxidation of tyrosine by rat liver, with particular reference to thiamine. *Proc. Soc. Exp. Biol. Med.*, 1954, 87, 97-100. [Dept. Biochem., Coll. Agric., Univ. Wisconsin, Madison.]

Manometric methods were used to measure the oxygen uptake of liver enzymes from rats given purified diets with or without vitamin B₁. Tyrosine oxidase activity was raised in livers from animals deprived of vitamin B₁. After dialysis activity was restored to deficient but not to normal liver preparations by addition of ascorbic acid and glutathione, and was further increased by addition of 2:6-dichlorophenolindolphenol. Injection of vitamin B₁ for one day did not affect the tyrosine oxidase activity of the liver of deprived animals, but after 12 or 13 days' treatment activity decreased to that of normal livers. In rats given vitamin B₁, starvation for from 4 to 7 days raised the tyrosine oxidase activity of the liver. Stimulation of the enzyme by ascorbic acid and glutathione was less in livers of starved animals than in livers from rats deprived of vitamin B₁.

CACIOFFO, F. **Sul meccanismo d'azione della "orizotossina".** Contenuto di acido piruvico nei tessuti di colombi trattati con "orizotossina". [Mode of action of the "rice toxin". Pyruvic acid content of tissues of pigeons treated with "rice toxin".] *Quad. Nutrizione*, 1952, **12**, 505-520. [Ist. Fisiol. Umana, Univ. Palermo.]

Of 20 pigeons fed on polished rice, 10 received in addition, by intramuscular injection, an alcoholic extract emulsified with water of from 40 to 60 g. polished rice. When the birds of the second group showed signs of inco-ordination they were killed with corresponding birds of the first group. Within 8 days all the birds given the extract showed signs of polyneuritis, and lost weight and condition very rapidly. None of the birds not given the extract did so before they were killed. The mean pyruvic acid content in mg. per 100 g. for those given and not given extract, respectively, was for muscle 1.89 and 1.28, for blood 3.22 and 1.56, and for brain 0.92 and 0.47. It is concluded that the action of the rice toxin is to promote deficiency of vitamin B₁, perhaps by interfering with the phosphorylation of the vitamin. (See Absts. 235, 1415, Vol. 5.)—E. M. Hume.

1929

NATH, M. C. and CHAKRABARTI, C. H. **Studies on the effect of aceto-acetate and β -hydroxybutyrate on vitamin B₁, both *in vivo* and *in vitro*.** *Indian J. Med. Res.*, 1953, **41**, 257-266. [Dept. Biochem., Univ. Nagpur.]

Rabbits fed on germinated gram (*Cicer arietinum*) were injected intraperitoneally with from 100 to 250 mg. per kg. bodyweight daily of sodium aceto-acetate or β -hydroxybutyrate. Vitamin B₁ and pyruvate were estimated in the blood and urine at intervals. Excretion of pyruvate increased while that of vitamin B₁ decreased. The changes were

apparent in the urine earlier than in the blood, but in the latter a large increase in pyruvate and a decrease in vitamin B₁ were seen after 90 days. Administration of vitamin B₁ restored the values for pyruvate in the blood and urine to normal.

When sodium acetoacetate was added to a solution of vitamin B₁ and incubated at pH 7.4, considerable destruction of the vitamin occurred. Sodium β -hydroxybutyrate had no apparent destructive effect *in vitro*, though it was as harmful as acetoacetate *in vivo*.—A. M. Copping.

1930

ONRUST, H. **Reactivating van door triphospho-oxythiamine geremde pyruvaat dehydrogenase. [Reactivation of pyruvate dehydrogenase inhibited by triphospho-oxythiamine.]** *Chem. Weekblad*, 1954, **50**, No. 2, 17. [Lab. Physiol. Chem., Univ. Amsterdam.]

Pyruvic dehydrogenase from animal tissue was completely inactivated by triphospho-oxythiamine. The system could be re-activated by addition of dried brewer's yeast.—A. M. Copping.

1931

HULPIEU, H. R., CLARK, W. C. and ONYETT, H. P. **The effect of thiamin deficiency produced by oxythiamin, by neopyrithiamin, and by diet, on the metabolism of alcohol.** *Quart. J. Studies Alcohol*, 1954, **15**, 189-206. [Dept. Pharmacol., Indiana Univ. Sch. Med., Indianapolis.]

It has been generally held that vitamin B₁ plays no part in the metabolism of alcohol, but it was desired to investigate whether the vitamin intervenes at any point in either of the two stages of alcohol oxidation, that to acetaldehyde and then, probably, to acetate.

Certain metabolites were estimated in the blood of dogs given alcohol and made deficient in vitamin B₁ by diet or with antagonists, with and without previous administration of Antabuse (disulphiram) which interferes with the metabolism of alcohol at the second stage of oxidation. The dose of ethanol was 1 g. per kg. bodyweight, diluted and injected intravenously. With 50 dogs normal blood values were established for acetaldehyde, pyruvic acid and glucose.

With 6 subcutaneous injections of oxythiamine, deficiency was produced within 24 hr.; classical neurological signs were lacking but the dogs were ill and might die. The pyruvic acid value in the blood rose and was used as criterion of deficiency. Amounts of alcohol which in normal dogs had only a slight effect caused death; blood glucose fell but acetaldehyde did not rise. Pyruvic acid rose further after a brief preliminary fall. If Antabuse had been given previously, but not otherwise, acetaldehyde rose steeply. Simultaneous administration of vitamin B₁ completely prevented the

N.A. and R., April 1955

effects of oxythiamine. In dogs made deficient with oxythiamine, a dose of acetaldehyde injected over 4 hr. instead of alcohol caused blood glucose to fall, but without oxythiamine it did not do so.

Deficiency could be produced with pyriethamine, only by simultaneous partial deprivation of vitamin B₁ in the diet; convulsions then occurred and pyruvic acid in the blood rose. Administration of alcohol had no adverse effect and glucose in the blood did not fall. When deficiency was produced with diet alone, the results with alcohol were the same as when it was produced with the aid of pyriethamine.

It is suggested in explanation of the results that cocarboxylase (vitamin B₁ pyrophosphate) is necessary for some phase in the metabolism of alcohol, and that oxythiamine acts by blocking or lowering tissue cocarboxylase.—E. M. Hume.

1932

BALAKRISHNAN, S. and RAJAGOPALAN, R. Effect of feeding curds, sulphaguanidine and *para*-amino benzoic acid on the coliform organisms and biosynthesis of thiamine. *Indian J. Dairy Sci.*, 1954, 7, 126-134. [Dept. Biochem., Indian Inst. Sci., Bangalore.]

During 4 successive tests, 18 rats weighing from 80 to 100 g. received a purified diet lacking vitamin B₁ without supplement for 4 days and with sulphaguanidine for 7 days; 12 of the rats were then given vitamin B₁ and 6 had milk curds and vitamin B₁ for 10 days; finally sulphaguanidine was given in addition to the vitamin B₁ and 6 rats had *p*-aminobenzoic acid as well. Urinary and faecal vitamin B₁ excretion was measured and the coliform organisms in the faeces were counted. Sulphaguanidine greatly reduced excretion of vitamin B₁ and also the number of coliform organisms in the faeces; its effect was prevented by *p*-aminobenzoic acid and by curds. When curds were given without sulphaguanidine excretion of vitamin B₁ and the number of coliform organisms increased.

BOROS, E., HÄNDEL, M., HERRMANN, G. and SÓS, J. Unterschiede in der Nahrungswahl von Ratten mit neurogener und renaler Hypertonie. [Differences in food choice of rats with hypertension of nervous and renal origin.] *Acta physiol. hung.*, 1954, 6, 321-329. [2. Med. Klin., Med. Univ., Budapest.] Russian summary.

Blood pressure was raised in adult rats by application of electric stimuli for 10 min. 3 times daily for 40 days, or by removal of one kidney and ligation of the other. Three groups of 10 rats,

normal, or with nervous, or with renal hypertension, were kept in separate cages and offered in separate containers a complete balanced diet, a high-protein diet, a low-protein diet, a diet rich in vitamin B₁ and a diet without vitamin B₁. Consumption was recorded from the eighth to the twenty-fourth day of the experiment. Normal rats ate chiefly the complete and the high-protein diets. Rats with nervous hypertension ate more of the diet rich in vitamin B₁ than of any other food. Those with renal hypertension showed a preference for the low-protein diet, though their consumption of protein, fat and carbohydrate over the whole period did not differ much from that of normal rats. They showed no desire for vitamin B₁.—A. M. Copping.

1934

BOWDEN, H. Aneurin bei der Regeneration und Degeneration. [Vitamin B₁ in regeneration and degeneration.] *Ztschr. Vitamin-, Hormon-Forsch.*, 1954, 6, 81-93. [Zool. Inst., Univ. Graz.] English and French summaries.

Vitamin B₁ was estimated with *Phycomyces* in samples of from 30 to 50 mg. of the leg muscle from guineapigs or the tail of tadpoles, killed at intervals after injury to the nerves. From the results the author considers that in nerve and muscle after such injury there is a decrease of vitamin B₁ content while any degeneration is going on, but that in the course of regeneration there is usually an increase of vitamin B₁ content in the tissue from which the regeneration emanates.

- POVOLOTZKAYA, K. L. O novoi svyazannoi s belkom forme riboflavina. [A new compound of protein with riboflavin.] *Biokhimiya*, 1953, **18**, 638-643. [Inst. Biokhim. A. N. Vakh, Akad. Nauk SSSR, Moscow.]

Experiments are described, arising out of the observation that autolysis increased the riboflavin content of certain tissues. The results pointed to the existence of a previously unknown riboflavin-protein compound, split by proteolytic enzymes such as trypsin, and not detectable by existing chemical and microbiological methods of estimating riboflavin.—D. W. Taylor.

1940

- PLAUT, G. W. E. Biosynthesis of riboflavin. 2. Incorporation of C^{14} -labeled compounds into ring A. *J. Biol. Chem.*, 1954, **211**, 111-116. [Inst. Enzyme Res., Univ. Wisconsin, Madison.]

Compounds containing ^{14}C were added to cultures of *Ashbya gossypii*, and riboflavin was isolated from the cultures and examined for the site of incorporation of the labelled C atom. Degradation of the riboflavin with chromic acid, NaN_3 and H_2SO_4 isolated the C-methyl groups and carbons 6 and 7. Degradation with strong alkali, HNO_3 , $KMnO_4$ and heat gave carbon atoms 5, 8 and 10a. When glucose-1- ^{14}C and glucose-6- ^{14}C were added to the cultures ^{14}C was found mainly in the methyl groups and in carbons 5 and 8. With $CH_3^{14}COOH$ most of the ^{14}C was incorporated into carbons 6, 7, 8a and 10a. With $^{14}CH_3COOH$ the presence of ^{14}C was less regularly distributed in the riboflavin molecule. The results are considered to suggest a possibility that 2-carbon fragments may be the basic building blocks in riboflavin biosynthesis.

- SESTAN, N. Contribution à l'étude de l'absorption et de l'excrétion de la riboflavine dans diverses conditions nutritionnelles et physiologiques. [Absorption and excretion of riboflavin under different nutritional and physiological conditions.] *Thesis, Univ. Paris*, 1954, pp. iii-119.

For the study of intestinal absorption and faecal and urinary excretion of riboflavin in the

rat a fluorimetric method of estimation with a Spekker photometer was adopted. A detailed investigation was made of methods of estimating riboflavin and of satisfactory conditions for the biological experiments. Titanium oxide was chosen as marker in the diet, and the first tests were made with diets containing adequate riboflavin.

Almost all the riboflavin present in the diet was found in the upper part of the small intestine. Absorption did not occur from the stomach but progressively along the small intestine, and the amounts remaining in the caecum, colon and faeces were almost constant. The amount of riboflavin excreted in the faeces was the same after a period of deprivation as during full supplementation. Attempts by giving sulphonamide drugs to ascertain whether faecal riboflavin is of endogenous or exogenous origin produced inconclusive results. Simpler experiments in which faecal excretion was measured during prolonged deprivation were considered as proof that faecal riboflavin was chiefly endogenous and derived from bacterial synthesis.

Urinary excretion of riboflavin was measured with varying amounts of riboflavin in the diet of normal adult rats, pregnant and lactating does, and newly weaned young. In adult rats the excretion of riboflavin was closely related to the intake. During the latter part of pregnancy and throughout lactation the amounts excreted were low. If the maternal diet was poor in riboflavin the young excreted little at weaning, but if the mother had received large amounts the young excreted a great excess in the first few days after weaning. As an indication of the state of riboflavin nutrition the urinary excretion seemed more satisfactory than the faecal excretion.

- GRAINGER, R. B., O'DELL, B. L. and HOGAN, A. G. Congenital malformation as related to deficiencies of riboflavin and vitamin B_{12} , source of protein, calcium to phosphorus ratio and skeletal phosphorus metabolism. *J. Nutrition*, 1954, **54**, 33-48. [Dept. Agric. Chem., Univ. Missouri, Columbia.]

Basal diets containing, as source of protein, maize and wheat gluten, or alpha protein, or water-washed casein, or soya bean oilmeal, were used in the study of congenital malformations in rats. Diets containing maize and wheat gluten or soya bean protein and lacking vitamin B_{12} and riboflavin produced a high incidence of hydrocephalus, ocular defects and skeletal abnormalities. With the gluten diet considerable, and with soya bean complete, protection was given by addition of vitamin B_{12} and riboflavin. Omission of vitamin B_{12} alone caused hydrocephalus, eye defects

N.A. and R., April 1955

and bone defects. Lack of riboflavin increased the incidence of skeletal abnormalities. If the Ca to P ratio was high the effect of B vitamin deficiencies on the skeleton was accentuated. Alkaline phosphatase and the rate of P deposition were estimated in some litters and were found to be less than normal in offspring of rats deprived of riboflavin and vitamin B₁₂.—A. M. Copping.

[Observations on the guineapig fed on artificial purified ration free from nicotinic acid.]** *Bull. Soc. Chim. biol.*, 1954, **36**, 1009-1014. [Lab. Chim. Agric., Conservatoire Nat. Arts et Métiers, Paris.]

In an initial test 11 guineapigs were given a purified diet containing 21 per cent. casein and 10 mg. nicotinic acid per 100 g. diet for from 45 to 126 days, and were then deprived of nicotinic acid for from 14 to 66 days. During the period of deprivation no sign of deficiency developed and no change was seen at autopsy. In a second experiment 11 young guineapigs received the purified diet with no nicotinic acid from the start; 4 failed

to adapt themselves to the diet. The remaining 7 showed retardation of growth, except 2 animals which showed no sign of deficiency; 2 animals died in 52 and 67 days and 3 were treated with nicotinic acid but only one recovered. None of the signs of nicotinic acid deficiency shown by other species occurred in the deprived guineapig.

Trigonellin was estimated daily for 18 days in the 24-hr. urine of 21 rats which, for from 110 to 155 days previously, had been subjected to partial interference with the blood supply to the liver or to ligation of the bile duct. Injury to the liver was subsequently confirmed histologically. Administration of a single dose of 5 mg. vitamin B₁ alone or with 35 mg. choline was followed by a small, transitory increase in the amount of trigonellin excreted. (See Abst. 1588, Vol. 23.)

In a similar experiment removal of a portion of the liver was followed by a temporary increase in the amount of trigonellin in the urine of rats. Administration of 10 mg. vitamin B₁ at the time of

operation did not affect the result. If the rats were treated with 2.5 mg. vitamin B₁ daily for 6 days before the operation, the amount of trigonellin rose and then fell again and was not affected by the operation.—E. M. Hume.

VILLA, L. and DIOGUARDI, N. Ulteriori ricerche intorno a fattori influenzanti la respirazione endogena dell'omogenato di fegato: interferenza della nicotinamide nella ossidazione dell'acetato per parte dell'omogenato di fegato. [Factors influencing endogenous respiration in liver homogenates: interference by nicotinamide in the oxidation of acetoacetate by liver homogenates.] *Arch. Sci. biol., Bologna*, 1954, **38**, 449-462. [Ist. Clin. Med. Gen., Univ. Milan.]

The effect of adding nicotinamide on the oxygen consumption of liver homogenates from rats maintained on different diets was studied in a Warburg apparatus. The diets were given for from 20 to 40 days before the experiment.

When the rats had been given complete diet, addition of nicotinamide reduced oxygen consumption, but if they had been fasted for from 1 to 8 days before the experiment, addition of nicotinamide increased it. With a low-protein diet, whether the rats were fasted or fed, nicotinamide increased oxygen consumption. With a low-protein, high-fat diet, the effect was the same when the rats were fed, but was less marked or absent when they had fasted. In rats on a high-protein diet, nicotinamide reduced oxygen consumption, and still more so when the rats had fasted.

The effect of different oxidisable substrates in the presence of nicotinamide was studied with the same technique with liver from rats fed on a complete diet and not fasting. The results for 23 substances are tabulated; the effect of nicotinamide was on the whole inhibitory, but with Na acetoacetate there was marked stimulation. With acetone or ethanol or both there was no such effect. Malonate had no effect on the action of nicotinamide whether the rats had been fasted on a complete diet or fed on a low-protein diet.

It is concluded that nicotinamide increased oxygen consumption in any conditions which increased the fat content of the liver, and that the type of oxidation studied was not related to the cycle of Krebs.—E. M. Hume.

SUBRAHMANYAM, K. Transformation of L-tryptophane into nicotinic acid in liver slices of the young rat in the presence of some of the vitamins of the "B" group. *Indian J. Med. Res.*, 1954, **42**, 359-361. [Dept. Biochem., Sri Ram Chandra Bhanj Med. Coll., Cuttack.]

Six young rats were fed on a purified diet without the vitamin B complex. After 21 days they were killed and slices of the livers were incubated in phosphate buffer with tryptophan, alone or with single vitamins of the B complex. Only in the presence of pyridoxine did any considerable conversion of tryptophan to nicotinic acid occur. With vitamin B₁, riboflavin, choline or pantothenic acid the amounts were negligible, and with no added B vitamin there was none.

MIYAKE, A., BOKMAN, A. H. and SCHWEIGERT, B. S. 3-Hydroxyanthranilic acid metabolite. 6. Chemical studies on intermediate. *J. Biol. Chem.*, 1954, **211**, 391-404. [Div. Biochem. Nutrit., Amer. Meat Inst. Found., Chicago, Ill.]

Optimum conditions were studied for obtaining an accumulation of the unstable intermediate compound formed during the conversion of 3-hydroxyanthranilic acid to quinoline by a rat liver enzyme. The reaction took place at pH 7 and formation of the intermediate was measured spectrophotometrically. Metabolism of 3-hydroxyanthranilic acid was stimulated by ferrous ions and ascorbic acid; it was inhibited by $\alpha\alpha'$ -dipyridyl, ethylenediaminetetra-acetic acid, or *o*-phenanthroline, and partly inhibited by iodoacetate and hydroxylamine. A compound isolated from the intermediate phase had quinone structure and was a degradation product of the true intermediate. It is suggested that in the metabolism of 3-hydroxyanthranilic acid an *o*-quinoneimine is formed which is readily hydrolysed to an *o*-quinone. A diagram of the probable metabolic system with spectral absorption maxima for the intermediates is given.

LONG, C. L., HILL, H. N., WEINSTOCK, I. M. and HENDERSON, L. M. Studies of the enzymatic transformation of 3-hydroxyanthranilate to quinolinate. *J. Biol. Chem.*, 1954, **211**, 405-417. [Div. Biochem., Noyes Lab. Chem., Univ. Illinois, Urbana.]

N.A. and B., April 1955

In the enzymic transformation of 3-hydroxy-anthranilate to quinolinate, evidence for the participation of two intermediate products was obtained. An unstable intermediate required ferrous iron for its formation; it was spontaneously converted into quinolinate, but on acid treatment it yielded a more stable product which was not converted to quinolinate. Observations on the effect of pH on the absorption spectrum of the stable intermediate are reported. It is suggested that conversion of the unstable to the stable compound involved formation of a substance with carbonyl characteristics.—A. M. Copping.

Homogenates of 12-day chick embryos were incubated at 37° C. for 24 hr. in Krebs Ringer phosphate solution with or without 3 mg. of 3-hydroxyanthranilic acid per g. homogenate. The preparations were autoclaved and nicotinic acid was estimated with *Lactobacillus arabinosus* in them, and in the hydroxyanthranilic acid separately. For the last the values were nil. The mean values, in µg. nicotinic acid per g. embryo, were 27.7 with

range 17.0 to 40.0 in the homogenate without hydroxyanthranilic acid, and 36.2 with range 23.7 to 45.2 with it. Every one of 16 preparations showed the effect.

In experiments like the last, quinolinic acid in a range of concentrations was used instead of hydroxyanthranilic acid, but no formation of nicotinic acid could be demonstrated.—E. M. Hume.

1958

DALGLIESH, C. E. Thiamine and tryptophan metabolism. *Biochim. biophys. Acta*, 1954, **15**, 295-296. [Postgrad. Med. Sch., London.]

The metabolic pathway from tryptophan to nicotinic acid is briefly outlined. Results of giving tryptophan to rats deprived of vitamin B₁ or of both vitamin B₁ and vitamin B₆ were studied. In vitamin B₁ deficiency in the rat, the conversion of tryptophan to nicotinic acid derivatives is known to be reduced. When both deficiencies were present the metabolites excreted at first were typical of those in pyridoxine deficiency, the metabolic pathway being blocked at the kynurenine stage. As the concomitant vitamin B₁ deficiency developed the excretion of the metabolites characteristic of vitamin B₆ deficiency decreased and finally disappeared except for a small amount of xanthurenic acid. If vitamin B₁ was given, the excretory pattern returned to that of pyridoxine deficiency. Further tests of giving kynurenine to animals deficient in both vitamins suggested that in tryptophan metabolism vitamin B₁ might be operative at an earlier stage than pyridoxine.

Blood studies were made in 3 experiments with rats taken at weaning, at 11 weeks of age, or at 6 months of age, and given a purified diet with or without pyridoxine hydrochloride. The weanling rats survived deprivation for 59 days and the older rats for up to 159 days. During deprivation there was a progressive increase in the red cell count. Estimation of plasma volume and plasma protein showed no haemoconcentration. Hb value and haematocrit were not significantly altered in the early stages of the deficiency and were only slightly decreased in the later stages. The blood picture of the deficient rats was microcytic and normochromic.—A. M. Copping.

OLSEN, N. S. and MARTINDALE, W. E. Studies on chronic vitamin B₆ deficiency in the rat. 1. Changes in the intact animal. 2. Changes in tissue metabolism. *J. Nutrition*, 1954, **53**, 317-327; 329-340. [Res. Lab., Veterans Admin. Hosp., Nashville, Tenn.]

1. Chronic vitamin B₆ deficiency was produced in rats by a purified diet containing, per cent., casein 24, dextrose 62, fat 10, salt mixture 4, and a vitamin mixture without vitamin B₆. Deoxypyridoxine was given for the first four weeks and then withdrawn; the rats survived for up to 34 weeks. Typical signs of severe deficiency appeared in some rats within a week of giving deoxypyridoxine, and the mortality rate was so high that it was not desirable to continue giving it. Rats on stock diet and rats receiving vitamin B₆ as well as deprived animals ceased to gain weight after 16

weeks but the maximum weight attained by the different groups ranged from 429 g. on stock diet to 220 g. on deficient diet. Pyridoxal hydrochloride added to the deficient diet quickly increased growth and cured the gross lesions.

Systolic blood pressure was measured throughout and showed a significant increase in animals deprived of vitamin B₆. The blood pressure was reduced when pyridoxal hydrochloride was added to the diet. No significant change in Hb content or red cell count was found, but a decrease in the white cell count occurred in deficient rats. No vascular or sclerotic lesion or histological change was seen in the heart, lung, liver, spleen, pancreas, adrenal glands, kidneys, testis or brain.

Extracellular fluid volume was measured with radio-active Na in a few rats from each group and no significant difference was found.

2. At the end of the experiment just described, the wet weights of the adrenal glands, liver, kidneys and ventricular mass of the heart were recorded. All were greater in rats deprived of vitamin B₆ than in animals on normal or purified diets or on a restricted food intake. The vitamin B₆ content of the liver and kidneys estimated with *Saccharomyces carlsbergensis* was low in deficient rats.

The oxygen uptake of broken-cell preparations measured manometrically decreased by 30 per cent. in the liver tissue, and 20 per cent. in the kidney tissue, of deprived rats. Addition of pyridoxal *in vitro* caused a rise of the oxygen uptake to normal in tissue preparations from deficient rats. The rate of oxidation of some amino-acids and amines added to the substrate did not differ for normal and deficient animals. With chemical complexes of pyridoxal and amino-acids the increase observed in the oxygen uptake of deficient tissues was less. The failure to metabolise the complexes completely is attributed to a low concentration of free vitamin B₆ in the tissues of deficient animals. The nature of the pyridoxal complexes and their relation to the transaminase and decarboxylase functions of vitamin B₆ are discussed.—A. M. Copping.

CHIANCONI, F. M., GINOULIAC, E. and TENCONI, L. T. Lesioni biochimiche della carenza di piridossina e loro specificità. [Biochemical lesions of pyridoxine deficiency and their specificity.] *Acta vitaminol.*, 1954, **8**, 209-213. [Lab. Direzione Med. Cent., Lepetit S.p.A., Milan.] French, English, German and Spanish summaries.

Of 16 male rats aged from 30 to 40 days, 4 had a complete diet and the rest a diet without vitamin B₆. After 36 days all were given by mouth a single dose of 500 mg. L-tryptophan per kg. body-weight. Of those having the deficient diet, 4 were given 250 µg. pyridoxine hydrochloride and 4 were

given 250 µg. riboflavin, of which part was given by mouth 30 min. before the dose of tryptophan and part subcutaneously immediately after it; 4 had no addition. Urine was collected for the ensuing 24 hr. The amounts of N¹-methylnicotinamide and nicotinic acid in the urine were greater with the complete diet than with any of the experimental diets, for which the amounts did not differ greatly. The amount of xanthurenic acid in the urine was least with the complete diet and only slightly greater with the experimental diet with added pyridoxine; without pyridoxine, whether riboflavin was added or not, the amount of xanthurenic acid was very much greater. For kynurenine, the results were similar to those for xanthurenic acid, but the amount with a complete diet was considerably less than with the experimental diet with added pyridoxine.—E. M. Hume.

BEATON, J. R. and GOODWIN, M. E. Studies on the effect of vitamin B₆ deprivation on carbohydrate metabolism in the rat. *Canad. J. Biochem. Physiol.*, 1954, **32**, 684-688. [Dept. Pub. Health Nutr., Univ. Toronto.]

Rats weighing about 100 g. were given a purified diet with or without pyridoxine for 5 or 22 days. After an 18-hr. fast the heart blood and liver were taken under anaesthesia or, in one experiment, after the animals were killed by stunning and decapitation. After only 5 days' deprivation there were significant decreases in the blood sugar and liver glycogen, and after 22 days the reduction was large and the pyruvic acid and lactic acid in the blood were low. The lactic acid dehydrogenase was depressed in liver homogenates from the deprived rats. The importance of the early changes in carbohydrate metabolism in vitamin B₆ deficiency is discussed.—A. M. Copping.

1964

Methods were devised for manometric measurement of glutamic-aspartic and glutamic-alanine

N.A. and R., April 1955

transaminase activity of duck heart tissues. With homogenates from the heart of ducks deprived of vitamin B₆ the transaminase activity was less than for normal heart tissue. Transaminase activity could be restored *in vitro* by addition of pyridoxal phosphate to the system. Administration of pyridoxine, pyridoxamine or pyridoxal to the deprived ducks restored full transaminase activity to their heart tissues. An attempt to relate the change in transaminase activity to the Hb content of the blood in deprived ducks failed. Slices of ventricle from deficient ducks showed no abnormality in endogenous respiration or in rate of oxidation and utilisation of pyruvate and lactate.

BLAKLEY, R. L. Participation of pyridoxal phosphate in the enzymic synthesis of serine. *Nature*, 1954, 174, 652. [Jolin Curtin Sch. Med. Res., Australian Nat. Univ., Canberra.]

An enzyme preparation from acetone-dried rabbit liver powder synthesised serine on incubation with glycine, formaldehyde, tetrahydropteroyl-glutamic acid and bicarbonate buffer. If pyridoxal phosphate was added to the system the rate of serine formation was increased by more than 100 per cent. in some experiments. The enzyme was almost inactivated by incubation at 37°C. and pH 8.6 for 30 min., but activity was restored by further incubation in the presence of pyridoxal phosphate. Synthesis with the re-activated enzyme was up to 100 times the amount of serine formed with the almost inactivated enzyme.

SINITZYNA, A. L. Vliyanie B₆-avitaminoza na dezaminirovanie L-aminokislit i na sintez ikh iz α -keto i α -okskislit i amniaka v pecheni i pockakh krysy. [Effect of vitamin B₆ deficiency on the deamination of L-amino-acids and on their synthesis from α -keto- and

α -hydroxy-acids and ammonia in rat liver and kidney.] *Biokhimiya*, 1954, 19, 80-87. [Inst. Med. Biol. Khim., Akad. Med. Nauk SSSR, Moscow.]

Deficiency of vitamin B₆ is said to reduce the activity of aminophosphatases in the rat. Oxidative deamination of L-glutamic acid in liver homogenates, and amination of α -ketoglutaric acid in liver and kidney slices, was not significantly different from normal in deficient rats. Deamination of L-alanine and L-aspartic acid in liver homogenates was disturbed. Incubation of liver and kidney slices with pyruvate and ammonia yielded only glutamic acid in appreciable amounts. Synthesis of phenylalanine and histidine from phenylpyruvic acid and imidazole-lactic acid was almost independent of added ammonia and ceased in vitamin B₆ deficiency. The results are taken to prove that the processes studied, except in respect of glutamic acid and α -ketoglutaric acid, depend on transamination.

MAKINO, K. and KOIKE, M. Competitive inhibition of pyridoxal phosphate action by toxopyrimidine phosphate in the tyrosine decarboxylase system. *Nature*, 1954, 174, 1056-1057. [Dept. Biochem., Med. Sch., Univ. Kumamoto, Japan.]

A possible relation between pyridoxal and toxopyrimidine was shown by Makino *et al.* (*Nature*, 1954, 173, 34; Abstr. 445, Vol. 25). An attempt was made to demonstrate a biological antagonism between toxopyrimidine phosphate and pyridoxal phosphate in the activation of a cell-free preparation of tyrosine apodecarboxylase prepared from *Streptococcus faecalis* R grown on a medium deficient in vitamin B₆. Toxopyrimidine at concentrations between $1 \times 10^{-10}M$ and $1 \times 10^{-6}M$ had no inhibiting effect, whatever the concentration of pyridoxal phosphate. Toxopyrimidine phosphate at concentrations of from $1 \times 10^{-10}M$ to $1 \times 10^{-7}M$ produced from 16 to almost 100 per cent. inhibition.—A. M. Copping.

EVERSON, G., NORTHERP, L., CHUNG, N. Y., GETTY, R. and PUDELKEWICZ, C. Effect of varying

Vol. 25, No. 2

the intake of calcium pantothenate of rats during pregnancy. 1. Chemical findings in the young at birth.

CHUNG, N. Y., NORTHERP, L., GETTY, R. and EVERSON, G. 2. Histological and histochemical studies of the liver, adrenal, duodenum, and tibia of the young at birth. *J. Nutrition*, 1954, 53, 341-350; 54, 97-105. [Nutrit. Lab., Dept. Home Econ. Res., Iowa State Coll., Ames.]

1. Young female rats were transferred immediately after the birth of a first litter to synthetic diets without calcium pantothenate or with 0.1 or

15

1.0 mg. daily. They were re-mated a week later and killed after the birth of their litters. Deprivation of pantothenate throughout pregnancy greatly reduced the size and number of the young. Those having 0.1 or 1.0 mg. produced about the same number and weight of young, but fewer than those produced by rats on stock diets. The pantothenic acid content of the tissues estimated with *Lactobacillus arabinosus* was low for the liver and carcass of the deprived mothers and for the carcass and blood of their young. A daily dose of 0.1 mg. raised the pantothenic acid content of the liver and carcass of the mother and the blood and carcass of the young to almost normal values and a dose of 1.0 mg. raised the values above normal. Newborn young with a very low concentration of pantothenic acid in the blood showed some accumulation of pyruvic acid. Ascorbic acid and alkaline phosphatase values in the serum of the young were not affected by the amount of pantothenate in the maternal diet.

2. In the young killed at birth, the liver, adrenal glands, duodenum and tibia were taken for histological study. No structural change was seen in any of the tissues and no important variation from normal could be demonstrated in the alkaline phosphatase content of the tissues. The period of pantothenic acid deficiency appeared not to affect the young that survived but a high proportion of litters was resorbed, so that any damage must have occurred in early prenatal life.

1970

EVERSON, G., NORTHROP, L., CHUNG, N. Y. and GETTY, R. Effect of ascorbic acid on rats deprived of pantothenic acid during pregnancy. *J. Nutrition*, 1954, 54, 305-311. [Nutrit. Lab., Dept. Home Econ. Res., Iowa State Coll., Ames.]

The effect was studied of including 2 per cent. of ascorbic acid in a diet otherwise devoid only of pantothenic acid in rats again pregnant after a successful pregnancy on a normal diet. The young were removed immediately after birth and the total pantothenic acid content of the blood of the young and of the tissues of mother and young was estimated with *Lactobacillus arabinosus*. With ascorbic acid in the diet the reproductive performance was better than on the diet without pantothenic acid and ascorbic acid. The pantothenic acid content of the blood of the young and of the tissues of the mother and young was raised by including ascorbic acid almost to the values attained with a full supplement of pantothenic acid. With ascorbic acid there was no rise of pyruvic acid, such as occurred in the blood of young rats from mothers deprived of pantothenic acid. It seemed that large amounts of ascorbic acid in the diet of the mother prevented the occur-

rence of any sign of pantothenic acid deficiency in the young.—A. M. Copping.

1971

WELCH, B. E. and COUCH, J. R. Vitamin B₁₂ and sub-optimal levels of pantothenic acid in chick nutrition. *Proc. Soc. Exp. Biol. Med.*, 1954, 87, 121-123. [Dept. Poultry Husb., Texas Agric. Exp. Stat., College Station.]

In day-old chicks which received for 4 weeks a basal diet containing, per kg., 10.5 mg. pantothenic acid, and supplemented with 1.66 mg. pantothenic acid, growth was decreased by supplements of 50 µg. vitamin B₁₂ per kg. With increase in the amount of vitamin B₁₂ growth was further reduced and signs of pantothenic acid deficiency became progressively more pronounced. When the supplements of pantothenic acid were increased to 3.32 and 6.64 mg. per kg. diet growth improved and the signs of deficiency disappeared. Further additions of pantothenic acid were without effect. Addition of vitamin B₁₂ up to 100 µg. per kg. diet progressively increased the vitamin B₁₂ content of the liver, and it was still further increased by adding pantothenic acid, 3.32 and 6.64 mg. per kg. diet. The results suggested a sparing effect on vitamin B₁₂ of pantothenic acid. The pantothenic acid content of the liver was increased only when supplements of 6.64 mg. or more of pantothenic acid per kg. diet were given.—E. M. Cruickshank.

1972

CASCIO, G., DOLCINI, C. and TACCHI, V. Sul comportamento della glicemia, del glicogeno epatico, cardiaco e muscolare e dei lipidi totali del fegato di ratti albini dopo somministrazione di acido pantothenico. [Behaviour of the blood sugar, of the liver, heart and muscle glycogen, and of the total liver lipids in the albino rat after administration of pantothenic acid.] *Bol. Soc. ital. Biol. sper.*, 1954, 30, 90-92. [Ist. Fisiol., Univ. Perugia.]

Of 12 young adult male rats maintained on a mixed diet, 4 were killed without any treatment, and 8 were given a single subcutaneous injection of 100 mg. pantothenic acid; 4 of them were killed after 90 min. and 4 after 240 min. The glycogen content of the muscle decreased slightly and progressively, that of the heart was unaffected, that of the liver was considerably increased after 90 min. and had fallen again after 240 min. Blood sugar too was higher after 90 min., and had fallen again after 240 min. Total lipids in the liver increased considerably and progressively.

acid on the respiratory gaseous exchange of normal pigeons.]

- RUBINO, F. and PENNETTI, V. Azione dell'acido pantoténico sul consumo di O_2 del fegato di colombi normali e di colombi ipertiroidizzati sperimentalmente. [Effect of pantothenic acid on oxygen consumption by the liver of normal pigeons and of pigeons with experimental hyperthyroidism.] *Bol. Soc. ital. Biol. sper.*, 1954, **30**, 403; 404-405. [Ist. Naz. Nutriz. C.N.R.]

The oxygen consumption and respiratory quotient were estimated in 6 pigeons fed on a normal diet, and then daily for 6 days while 100 mg. pantothenic acid were being given. The R.Q. was unchanged but oxygen consumption was reduced by the treatment.

Oxygen consumption was measured in liver homogenates of pigeons treated as just described, or as just described with addition of 0.5 mg. thyroxine daily, or with thyroxine but without pantothenic acid. The rise in oxygen consumption promoted by thyroxine was partly countered by pantothenic acid.—E. M. Hume.

The biological potency for chicks of the *Lactobacillus bulgaricus* factor, pantethine, was com-

pared with that of calcium pantothenate given in the diet, or directly by mouth or by intraperitoneal injection. Pantethine had about 90 per cent. of the potency of pantothenate given orally but was equally potent given parenterally. Pantetheine, which is a reduced form of pantethine, and the mercury mercaptide of pantetheine were as potent as pantethine if given directly by mouth or by injection.—A. M. Copping.

- THOMPSON, R. Q. and BIRD, O. D. *In vivo* activity of pantothenylcyst(e)ine for rats and chicks. *Science*, 1954, **120**, 763-764. [Res. Labs., Parke, Davis and Co., Detroit, Mich.]

In view of reports that pantothenylcysteine had growth-promoting activity for certain micro-organisms, it was tested on young chicks and rats given diets lacking in pantothenic acid. Whether given with the diet or injected it failed to promote growth in chicks or rats deprived of pantothenic acid.—A. M. Copping.

Chem., Univ. Frankfurt a.M.]

An analogue of pantothenic acid was synthesised with ethyl groups instead of methyl groups in the butyrolactone part of the molecule. The analogue showed small but definite growth-promoting activity for *Streptobacterium plantarum* 10 S and *Saccharomyces carlsbergensis* 4228, the ratio of the potency of the ethyl-substituted analogue to that of the original pantothenic acid being about 1 to 1000.—A. M. Copping.

BIOTIN

1980

THOMA, R. W. and PETERSON, W. H. The enzymatic degradation of soluble bound biotin. *J. Biol. Chem.*, 1954, **210**, 569-579. [Dept. Biochem., Coll. Agric., Univ. Wisconsin, Madison.]

Free biotin was estimated with *Lactobacillus arabinosus*. The total biotin content of peptic digests of liver was the amount measured by *L. arabinosus* after the liver had been hydrolysed for 2 hr. at 120°C. with 4*N* H₂SO₄. The soluble, bound biotin which was made available by acid hydrolysis could be freed also by treatment with an enzyme, biotinidase, obtained from fresh or acetone-treated pig's liver, or from pig's kidney or chick pancreas. Many other enzymes, including pepsin, trypsin, papain, proteases and esterases were tested, but only one, *Fusarium* lipase, showed biotinidase activity. Biotinidase could be separated from esterases by fractional precipitation with ammonium sulphate. Concentrated biotinidase hydrolysed biocytin and *p*-(*N*-biotinyl-amino)-benzoic acid, but not *N*-biotinyl-L-aspartic ester.—A. M. Copping.

1981

DELOST, P. and TERROINE, T. Effets de la carence en biotine sur certaines glandes endocrines au cours du développement post-natal du rat. [Effect of biotin deficiency on some endocrine glands during post-natal development of the rat.] *C.R. Acad. Sci.*, 1954, **239**, 902-904.

Three groups of male rats about 1 month old and weighing 40 g. were given a basal diet deficient in biotin (Abst. 452, Vol. 24), or the same diet with added biotin, given to appetite or restricted to the amount consumed by the rats on the deficient diet. Rats were killed for histological examination after from 1 to 11 weeks of the diets.

Biotin deprivation had no significant effect on the adrenal glands or on the histology of the thyroid gland, but progressive changes appeared in the testes, in which, by the end of the experiment, the seminiferous tubules had atrophied and no longer contained spermatozoa. Simple restriction of food intake had little effect on the testes.

SERVIGNÉ, M. and TERROINE, T. Troubles moteurs et teneur en potassium musculaire chez le rat carencé en biotine. [Locomotor disturbances and the potassium content of muscle in the biotin-deficient rat.] *Arch. Sci. physiol.*, 1964, **8**, 227-232. [Lab. Recherches Physicochim., Inst. Nat. Agronom., Paris.]

Young male rats weighing about 40 g. were given purified diets with or without biotin, and

when the deprived animals showed severe alopecia, hunched backs and kangaroo gait all were killed and the K content of the muscles was estimated. On the average, the values were about 15 per cent. lower in the deprived rats than in the non-deprived, but the signs of severe deficiency were not invariably accompanied by low values for K in the muscles, which did not seem to be the chief cause of the changes in posture and gait in the deficiency.—A. M. Copping.

1983

CARR, L. M. A toxic effect of fluoride. *Nature*, 1954, **174**, 884-885. [Dept. Health, Canberra.]

Experiments were made with rats to test whether fluoride, by its depressing effect on bacterial activity, might produce signs of vitamin deficiency after the manner of sulpha drugs or antibiotics. Two groups of 3 rats were given a semi-synthetic diet with a vitamin mixture but without biotin; one group had 80 p.p.m. F as NaF added to the drinking water and the other had no added F. At the end of 3 weeks the average weights were 178 and 204 g. for those with and without fluoride, respectively. The diet was then changed to a synthetic one, containing 16 per cent. raw egg white, with the same vitamin supplement, and after 16 days the respective average weights were 125 and 196 g. In the group given fluoride signs of biotin deficiency appeared and 1 rat died; the animals without fluoride were free from such signs.

Other similar experiments are mentioned which suggest that the effects may be due to a biotin deficiency complicated by other conditions or to an unknown form of toxicity resulting from the use together of egg white and fluorine. They will be reported later in detail.—D. Harvey.

1984

HOFMANN, K. and PANOS, C. The biotin-like activity of lactobacillic acid and related compounds. *J. Biol. Chem.*, 1954, **210**, 687-693. [Dept. Biochem., Sch. Med., Univ. Pittsburgh, Pa.]

Cyclopropane fatty acids of the *trans*-series were synthesised as previously described (*J. Amer. Chem. Soc.*, 1954, **76**, 1799) and tested for their growth-stimulating effect on organisms known to require biotin. Lactobacillic acid and three related acids, and oleic, elaidic, *cis*-vaccenic and *trans*-vaccenic acids all showed growth effects for *Lactobacillus arabinosus* and *L. casei*. *L. delbrueckii* did not respond to *trans*-vaccenic acid and *Clostridium butyricum* and *L. acidophilus* did not respond to most of the acids tested. The growth effect

N.A. and R., April 1955

appeared to depend on the presence of a chain of more than 11 carbon atoms, since shorter-chain compounds failed to support growth.

1985

GOTHOSKAR, S. S. and SREENIVASAN, A. **Biotin metabolism in micro-organisms.** 1. Biosynthesis. 2. Role of biotin in some oxidative systems. 3. Aspartic-acid oxidation and deamination. *Indian J. Med. Res.*, 1953, **41**, 51-57; 59-67; 69-84. [Dept. Chem. Technol., Univ. Bombay, Matunga.]

1. Synthesis of biotin was studied in cultures of *Bacterium coli* in a semi-synthetic medium containing a vitamin-free casein hydrolysate. Biotin was estimated with *Lactobacillus arabinosus*. Pimelic acid, urea or cystine separately added to the medium did not increase synthesis of biotin, but the three together did. Desthiobiotin in the medium caused a large increase in biotin production and no added cystine appeared to be required for the introduction of the sulphur atom into the biotin molecule.

2. The enzyme activities of normal and biotin-deficient cells of *L. arabinosus* were examined by manometric methods. Lactic and pyruvic dehydrogenases and serine oxidase systems were partly inactivated in the absence of biotin, but other enzymes were not affected. Normal *L. arabinosus* was able to dehydrogenate sodium salts of fatty acids, including laurate, myristate, palmitate and stearate, and this function, too, was impaired in biotin-deficient cells. It was increased in cells grown in media containing aspartate and oleate. Cells of *Bact. coli* contained a fatty acid dehydrogenase, the activity of which was less in cells deprived of biotin by ageing in a phosphate buffer. Biotin is considered to act indirectly, probably by influencing the synthesis of amino-acids in the enzymes studied.

3. The aspartic deaminase activity of resting cells of *Bact. coli* was not affected by addition of biotin and adenylc acid or by cultivation in media with added biotin, aspartate and oleate, or avidin. When the cells were aged at pH 4 the deaminase activity fell and was not restored by addition of biotin and adenylc acid, unless glucose and phosphate were present. The effects were the same in aerobic and anaerobic conditions. An attempt was made to correlate oxygen uptake and liberation of ammonia during oxidative deamination, but the oxygen uptake always exceeded the theoretical value. The aspartic oxidase activity was less in aged cells; it was not restored by biotin and adenylc acid alone, and was restored only to a small extent in presence of glucose and phosphate. The possible role of biotin in the different enzyme systems is discussed.—A. M. Copping.

SHANMUGA SUNDARAM, E. R. B., TIRUNARAYANAN, M. O. and SARMA, P. S. **The relation between biotin and tryptophan metabolism studied in *Neurospora crassa*.** *Biochem. J.*, 1954, **58**, 469-473. [Biochem. Lab., Univ. Madras.]

By the use of mutant strains of *Neurospora crassa* unable to synthesise nicotinic acid but capable of quantitative response to the metabolites formed during conversion of tryptophan to nicotinic acid, the importance of biotin for utilisation of tryptophan was demonstrated. Biotin appeared to function only in the conversion of tryptophan to formylkynurenine, and no other step in the reaction was affected by lack of biotin. Biotin deficiency was produced in the *Neurospora* cultures with the antagonist γ -(3:4-ureylenecyclohexyl)-butyric acid. Studies *in vitro* with suspensions of *Neurospora* mycelium showed accumulation of tryptophan if the antagonist was present in the medium.—A. M. Copping.

p-AMINO BENZOIC ACID

ARIËNS, E. J. **Affinity and intrinsic activity in the theory of competitive inhibition.** 1. Problems and theory.

ARIËNS, E. J. and SIMONIS, A. M. **2. Experiments with para-amino-benzoic acid derivatives.** *Arch. internat. Pharmacodyn.*, 1954, **99**, 32-49; 175-187. [Pharmacol. Lab., Univ. Utrecht.]

1. The first paper is a theoretical and mathematical discussion of the fact that "some drugs, while presumably reacting with the same receptor, were still able to produce opposite effects, depending on varying conditions". Such dualistic behaviour was explained "by extending the theory of com-

petitive inhibition with the concepts of *affinity* and *intrinsic-activity*", which are specially defined. Affinity is defined as the tendency of the drug to combine with the receptor; the intrinsic-activity determines the effect, such as velocity of enzyme action or of growth, that can be obtained with a certain amount of the metabolite-receptor complex.

2. In the second paper experimental results with some p-aminobenzoic acid derivatives and sulphanilamide compounds are described, a p-aminobenzoic-acid-deficient mutant of *Bacterium coli* being the organism used. The results of the experiments are held to support the theory put forward.—E. M. Hume.

1992

- AFONSKY, D. Folic acid deficiency in the dog. *Science*, 1954, 120, 803-805. [Dept. Dent. Res., Univ. Rochester, N.Y.]

Signs of folic acid deficiency occurred in a dog given a purified diet without folic acid or vitamin B_{12} . Folic acid, 30 mg., restored the blood picture to normal but vitamin B_{12} did not. After about 6 weeks the animal again became ill but was successfully treated with folic acid. When the dog was killed hypoplasia of the bone marrow and lesions of the tongue were found. In view of the findings folic acid was given to dogs having diets deficient in nicotinic acid, vitamin B_6 , riboflavin or pantothenic acid. It did not affect development of deficiency and did not enhance the effect of other vitamins when they were given in curative amounts. It is suggested that some dogs, but not all, may require folic acid.—A. M. Copping.

Normal female rats mated at from 3 to 4 months of age were given a diet lacking pteroylglutamic acid for from 2 to 11 days at different stages of pregnancy. When the deficient diet was given between the seventh and tenth day of gestation, from 28 to 57 per cent. of the young showed congenital cardiovascular anomalies at birth, even if the deprivation was for only 48 hr. The critical period was from the ninth to the eleventh day of gestation. If the deficient diet was given after the tenth day no abnormality developed. The cardiovascular anomalies found included interventricular septal defects, persistent truncus arteriosus, double or right aortic arch, absence of ductus arteriosus, aberrant origins of subclavian arteries and other variations of the arterial pattern derived from the embryonic arch system. No anomaly was found in young from mothers given stock diet or a purified diet supplemented with pteroylglutamic acid.—A. M. Copping.

WEINHOUSE, S. and FRIEDMANN, B. A study of formate production in normal and folic acid-deficient rats. *J. Biol. Chem.*, 1954, **210**, 413-421; 423-433. [Lankenau Hosp. Res. Inst., Philadelphia, Pa.]

The oxidation of ^{14}C -labelled sodium formate given intraperitoneally to fasting adult rats was studied with normal animals and animals deprived of folic acid, kept in a metabolism apparatus for 6 hr. after the injection. Rats deprived of folic acid had much less power to oxidise formate to CO_2 . Administration of folic acid restored the oxidation to normal. The defect was apparently in the metabolism and was not due to impairment in the absorption or excretion of formate. Studies were made *in vitro* with tissue homogenates and very low values were found in oxidation of formate by heart, kidney and liver from deprived rats; the catalase activity of liver too was low. The role of catalase in oxidation of formate is discussed with reference to the possible relation between folic acid and catalase activity.

The production of formate from glycine, choline, methionine or sarcosine labelled with ^{14}C was studied in normal rats and in rats deprived of folic acid. Tracer doses of the precursors were given with larger amounts of formate and the amounts of ^{14}C were measured in the urinary formate and the respiratory CO_2 during 6 hr. Rats deprived of folic acid produced more formate from the methyl groups of methionine, choline and sarcosine but less from the α -carbon of glycine than those given folic acid. Deprivation of folic acid caused a slight reduction in oxidation of methyl groups to CO_2 but strongly inhibited the oxidation of the α -carbon of glycine.

DOCTOR, V. M., COUCH, J. R. and TRUNNELL, J. B. Factors influencing conversion of folic acid to citrovorum factor by chick liver fractions. *Proc. Soc. Exp. Biol. Med.*, 1954, **87**, 228-231. [Sect. Exp. Med., Univ. Texas, College Station.]

A study was made of the effect of homocysteine, cysteine, cystine, glutathione and ascorbic acid on the enzyme system in chick liver that converts folic acid to citrovorum factor. The enzyme was present mainly in the supernatant fraction obtained when a liver homogenate was centrifuged. It was precipitated by 40 per cent. ethanol. Homocysteine had a specific stimulatory effect which was not shared by the other sulphhydryl compounds tested. Optimum activity was obtained in the presence of serine, homocysteine and magnesium when dried acetone extract of liver was used. It is suggested that unidentified factors present in chick liver homogenates are required for the conversion of folic acid to citrovorum factor.—A. M. Copping.

1998

LASCELLES, J. and WOODS, D. D. The synthesis of serine and *Leuconostoc citrovorum* factor by cell suspensions of *Streptococcus faecalis* R. *Biochem. J.*, 1954, **58**, 486-497. [Microbiol. Unit, Dept. Biochem., Univ. Oxford.]

Cells of *Streptococcus faecalis* R previously deprived of folic acid and vitamin B_6 synthesised serine on incubation in a buffered mixture of glycine, formate, glucose, pyridoxal and pteroylglutamic acid. Only about one-tenth of the amount of serine appeared if any one of the constituents of the mixture was omitted. Leucovorin and N^{10} -formylpteroylglutamic acid could replace folic acid. A substance required for growth of *Leuconostoc citrovorum* was synthesised at the same time as serine in the complete mixture; it could be formed also in the absence of glycine and pyridoxal. Synthesis of serine and the citrovorum factor was inhibited by N^{10} -methylptericoic acid in competition with folic acid. Serine was required for growth of *S. faecalis* R in a medium lacking folic acid and vitamin B_6 . The possible co-enzyme activities of folic acid or its derivatives in the synthesis of serine are discussed with reference to the findings.—A. M. Copping.

1999

BLAKLEY, R. L. The interconversion of serine and glycine: role of pteroylglutamic acid and other cofactors. *Biochem. J.*, 1954, **58**, 443-462. [Nat. Inst. Med. Res., Mill Hill, London; N.W.7.]

A study of the interconversion of glycine and serine was made with ^{14}C -labelled glycine and an enzyme prepared from pigeon liver. $2\text{-}^{14}\text{C}$ -Serine was formed from $2\text{-}^{14}\text{C}$ -glycine and L-serine. D-Serine did not react and no ^{14}C was found in the 3-C of serine. The labelled serine could be converted into glycine and formaldehyde. Pteroylglutamic acid was essential as a catalyst in the processes of interconversion; leucovorin had some catalytic effect but required simultaneous addition of yeast extract for a rapid reaction. Of other derivatives of pteroylglutamic acid studied, tetrahydropteroylglutamic acid was the most active catalyst. 4-Aminopteroylglutamic acid inhibited interconversion when pteroylglutamic acid was the catalyst, but not when the catalyst was leucovorin or tetrahydropteroylglutamic acid. The results are discussed and a scheme is suggested for the role of pteroylglutamic acid derivatives in metabolism of formate and transfer of C atoms.

HAMILTON, L., PHILIPS, F. S., STERNBERG, S. S., CLARKE, D. A. and HITCHINGS, G. H. (with WHEELLOCK, B. and DEBLEUX, A.) Hematological effects of certain 2, 4-diaminopyrimidines, antagonists of folic acid metabolism. *Blood, J. Hematol.*, 1954, **9**, 1062-1081. [Div. Exp. Chemotherap., Sloan-Kettering Inst., New York.]

Three substituted diaminopyrimidines tested on rats, mice, cats and dogs in sub-lethal doses

produced signs of folic acid deficiency. Ileitis, colitis and diarrhoea occurred in all the animals and stomatitis in the dogs. The blood changes produced by the antagonists were granulocytopenia and reticulocytopenia, and there were severe alterations in the bone marrow which caused abnormalities in blood cell development. Doses above the LD₅₀ caused acute convulsions. In mice simultaneous administration of citrovorum factor with doses in excess of the LD₅₀ of diaminopyrimidines did not prevent immediate death but did prevent the delayed fatal effect in some, though not in all. The failure to protect completely was interpreted as evidence that there may be unrecognised factors in cells, that are concerned in the transformation of folic to folinic acid.

2005

GREGORY, M. E. The microbiological assay of "vitamin B₁₂" in the milk of different animal species. *Brit. J. Nutrition*, 1954, **8**, 340-347. [Nat. Inst. Res. Dairying, Univ. Reading.]

"Vitamin B₁₂", defined as the total activity for the test organisms, was estimated in cow's and goat's colostrum (1), and in human milk and milk of the cow, goat, ewe (1), sow (4) and rat with 3 different organisms, *Lactobacillus leichmannii*, *Bacterium coli* and *Ochromonas malhamensis*, the last according to Ford (Abst. 1825, Vol. 24) being specific for cyanocobalamin. Methods of extracting vitamin B₁₂ from the milk samples by cyanide with acid or buffer or by digestion with papain were investigated. All samples were steamed. The results with *O. malhamensis* were close to those with the other organisms, which is evidence that vitamin B₁₂ in milk occurs chiefly as cyanocobalamin. Average values for the acid-cyanide extract were in µg. per ml. for ewe 9.5, rat 9.1, cow 2.3, goat 0.9, woman 0.2 and sow 0.0. Cow's and goat's colostrum contained 3.7 and 6.5 µg. per ml. When all samples were ultrafiltered no activity was found in the filtrate, which suggested that vitamin B₁₂ occurred in a bound form. After digestion with papain and cyanide the values were for woman 0.3 and sow 1.7. Other samples did not change appreciably. Unheated cow's milk had no activity for *L. leichmannii* and recovery of added cyanocobalamin was erratic, suggesting the presence of substances inhibiting the growth of the organism.—A. Hepburn.

VENKATARAMAN, P. R., DUBIN, A. and FRIEDEL, M. T. Influence of cortisone and vitamin B₁₂ on the growth and P³² uptake of adrenal and lymphoid tissue. *Metabolism*, 1954, 3, 502-505. [Hektoen Inst. Med. Res., Chicago, Ill.]

Weanling rats receiving a semi-purified diet with extracted soya bean meal as source of protein, after 2 weeks on the diet alone, were given vitamin B₁₂ or cortisone or both or no supplement. After another 2 weeks the animals were given intraperitoneal injections of 20 μ C. radio-active P and were killed 3 hr. later. Rats receiving cortisone and no vitamin B₁₂ showed retarded growth and atrophy of the adrenal and thymus glands, spleen and lymph nodes. If vitamin B₁₂ was given with cortisone the growth-inhibiting effects of the hormone were counteracted except for atrophy of the adrenal glands. Uptake of ³²P into the adrenal and thymus glands and spleen was inhibited by cortisone and was not restored to the same extent as growth when vitamin B₁₂ was given.

DRYDEN, L. P., HARTMAN, A. M. and CARY, C. A. Influence of vitamin B₁₂ upon vaginal patency in the rat. *Proc. Soc. Exp. Biol. Med.*, 1954, 87, 195-197. [Dairy Husb. Res. Branch, Agric. Res. Serv., U.S. Dept. Agric., Beltsville, Md.]

In young female rats from mothers which had received diets deficient in vitamin B₁₂ during lactation, there was delay in opening of the vagina if they themselves were fed from weaning on diets lacking vitamin B₁₂. If the maternal diet contained adequate vitamin B₁₂ the post-weaning diet of the young did not affect the onset of maturity. When casein was the source of protein in the diet the ages of maturity in the deprived and non-deprived were not affected by the source of carbohydrate. With soya bean protein maturity was earlier in the deprived rats with a mixture of lactose and dextrin than with maize meal or sucrose; the delay was greatest of all with soya bean protein and sucrose.—A. M. Copping.

2013

SCHWIGERT, B. S., SCHEID, H. E. and DOWNING, M. Liver changes in vitamin B₁₂ and riboflavin-deficient rats before and after partial hepatectomy. *Amer. J. Physiol.*, 1954, 178, 338-340. [Div. Biochem. Nutrit., Amer. Meat Inst. Found, Chicago, Ill.]

Weanling rats were given a diet of maize, soya bean oil meal and iodinated casein without vitamin B₁₂ or supplemented with 30 μ g. per kg., or a casein and sucrose diet without riboflavin or supplemented with 600 or 6000 μ g. per kg. After

4 weeks of the experimental diet about two-thirds of the liver was removed from some animals in every group, and weighed and analysed. The rats were killed 1 day or 4 days later and the remainder of the liver was taken for analysis. In the liver ribonucleic and deoxyribonucleic acids were estimated and cell counts were made as previously described (*Proc. Soc. Exp. Biol. Med.*, 1952, 79, 541).

Very few rats deprived of vitamin B₁₂ survived for 4 days after partial liver removal. Regeneration of liver tissue was less in rats deprived of vitamin B₁₂ than in the other groups. There was less ribonucleic and deoxyribonucleic acid in the liver of vitamin-B₁₂-deficient rats but not of those deprived of riboflavin. The findings are thought to provide further evidence for the specific role of vitamin B₁₂ in nucleic acid synthesis.

CHARKEY, L. W., KANO, A. K. and ANDERSON, J. A. Effects of fasting on free amino acid levels in chick blood as modified by vitamin B₁₂. *J. Biol. Chem.*, 1954, 210, 627-632. [Dept. Chem., Colorado Agric. and Mech. Coll., Fort Collins.]

Comparable groups of chicks were given a diet of soya bean meal and maize with or without a supplement of 50 µg. vitamin B₁₂ per kg. diet. After 2, 4 and 6 weeks chicks were killed before or after fasting for 48 hr., or 4 hr. after returning to feed. Blood samples were taken and the liver was removed. The amount of L-lysine, L-threonine, L-valine, L-leucine, and L-isoleucine was measured in the blood and all showed a clear increase during fasting when the birds were deprived of vitamin B₁₂, the increase being greatest for lysine and smallest for leucine. The age also of the chicks affected the amino-acid content of the blood, and the effect of fasting decreased with age. When vitamin B₁₂ was added to the diet the effect of fasting was less clearly seen and the vitamin appeared to regulate the amino-acid content of the blood. The content of vitamin B₁₂ in the liver was high in chicks receiving the vitamin, though the weight of the liver and total bodyweight were not affected.—A. M. Copping.

2015

RAMALINGASWAMI, V. and SRIRAMACHARI, S. The effect of vitamin B₁₂ on the toxicity of pyrimethamine (Daraprim) in the monkey. *Indian J. Malariol.*, 1953, 7, 305-306. [Nutrit. Res. Labs., Indian Council. Med. Res., Coonoor.]

Of 11 rhesus monkeys fed on a stock diet and given orally 10 mg. of the antimalarial drug pyrimethamine per kg. bodyweight daily, 5 were given in addition from 50 to 200 µg. vitamin B₁₂

by intramuscular injection. There was progressive loss of weight and granulocytopenia with death after from 12 to 20 days. The bone marrow showed arrest in the maturation of the myelocytes, and large numbers of abnormal giant myelocytes appeared, but there was no anaemia and no megaloblastic transformation of the marrow. Vitamin B₁₂ had no favourable effect on the condition and it is concluded that the effect of liver extract in alleviating the toxic effect of pyrimethamine (cf. *Abst.* 1641, Vol. 23) could not have been due to its content of vitamin B₁₂.—E. M. Hume.

2017

FANTES, K. H. and O'CALLAGHAN, C. H. The biosynthesis of a new vitamin B₁₂ analogue. *Biochem. J.*, 1954, 58, xxi. [Glaxo Laboratories, Ltd., Sefton Park, Stoke Poges, Bucks.]

2018

MANNINO, N. and PIPTONE, V. Metabolismo vitaminico di *E. coli* in presenza di antibiotici diversi. [Vitamin metabolism of *Bacterium coli* in the presence of different antibiotics.] *Bol. Soc. ital. Biol. sper.*, 1954, 30, 308-311. [Ist. Clin. Med., Univ. Bari.]

A strain of *Bacterium coli* was exposed for 12 or 48 hr. to graded concentrations of aureomycin, chloramphenicol, penicillin, streptomycin or terramycin. The amount of growth was estimated turbidimetrically, and the amounts of vitamin B₁₂ and folic acid formed were estimated microbiologically. The amount of both substances produced in the presence of the antibiotics was less in relation to the amount of growth than would have been expected in their absence.—E. M. Hume.

2019

REGGE, D. V. and SREENIVASAN, A. The influence of folic acid and vitamin B₁₂ on nucleic acid metabolism in microorganisms. *J. Biol. Chem.*, 1954, 210, 373-380. [Dept. Chem. Technol., Univ. Bombay.]

The effect of folic acid and vitamin B₁₂ on nucleic acid synthesis in *Lactobacillus casei* (*Abst.* 5061, Vol. 20) was further investigated with other micro-organisms. In *Streptococcus faecalis* R, which requires folic acid for growth, the production of deoxypentose nucleic acid varied with the folic acid content of the medium. In *Lactobacillus leichmannii*, which requires vitamin B₁₂, production of pentose nucleic acid varied with the vitamin B₁₂ content of the medium. In media not containing

purines, folic acid and vitamin B₁₂ showed separate and joint effects on synthesis of nucleic acid by *L. casei*. With *L. casei* and *S. faecalis* R vitamin B₁₂ could replace folic acid only as a stimulant to nucleic acid synthesis. Purine degradation by resting cells of *L. casei* was inhibited to some extent in the presence of folic acid and vitamin B₁₂. *Lactobacillus arabinosus* and *Bacterium coli* do not require folic acid or vitamin B₁₂, and their addition to the medium did not affect nucleic acid synthesis.—A. M. Copping.

JENKINS, K. J., BELL, J. M., O'NEIL, J. B. and SPINKS, J. W. T. The effects of antibiotics on the synthesis of vitamin B₁₂ in the chick. *Canad. J. Biochem. Physiol.*, 1954, **32**, 628-635. [Dept. Animal Husb., Univ. Saskatchewan, Saskatoon.]

A diet lacking vitamin B₁₂, with or without addition of radio-active cobalt as ⁶⁰CoCO₃, was given to chicks having penicillin, streptomycin, aureomycin, terramycin or no supplement. Co alone did not affect weight gains but gains were increased when Co and an antibiotic were given. Aureomycin and terramycin appeared superior to penicillin and streptomycin. The excretion of Co rose and that of vitamin B₁₂ fell in chicks receiving antibiotics. Estimation of Co and vitamin B₁₂ at all levels of the gastro-intestinal tract and in tissues showed that synthesis of vitamin B₁₂ began in the proventriculus and that the rate and site of synthesis were affected by the antibiotics. The amount of Co in the tissues was higher when no antibiotic was given. The vitamin B₁₂ content of all tissues, except the blood and gallbladder which showed high values, was little affected by administration of antibiotics. It is suggested that in chicks given no antibiotic the high values found in the blood and gallbladder were a sign of defective utilisation of the vitamin.—A. M. Copping.

SHERWOOD, D. H. and SLOAN, H. J. Vitamin B₁₂ and choline in corn-soy rations for starting poults. *Poultry Sci.*, 1954, **33**, 1015-1021. [Dept. Poultry Husb., Univ. Minnesota, St. Paul.]

Day-old poults from turkey hens given a practical ration received for 4 weeks a basal all-vegetable diet low in choline, with or without supplements of vitamin B₁₂ alone or with nicotinic acid and choline or with methionine. The addition to the basal diet of 10 µg. vitamin B₁₂ per kg. increased the growth rate significantly, but efficiency of feed utilisation was not consistently improved. Supplements of vitamin B₁₂ with choline or methionine still further increased growth and efficiency of feed utilisation also. Mortality was excessive on the basal ration and much less when choline was added but only slightly less with vitamin B₁₂. Nicotinic acid had little effect on growth rate or mortality. There was some evidence that prolonged storage of the ration reduced the amount of available choline. When the basal diet was supplemented with choline, the severity of gizzard erosion and the size of the gizzard were less.

WÖHLBIEH, W., ORTH, A., KUJUS, W. and HACKER, W. Schweinemast- und Kükenaufzuchtversuche mit Vitamin B₁₂-Präparaten. [Pig fattening and chick rearing with vitamin B₁₂ preparations.] *Arch. Tierernährung*, 1954, **4**, Beihefte, No. 4, 182-213. [Inst. Tierernährungslehre, Landw. Hochsch., Stuttgart, Hohenheim.]

The results of 6 experiments are summarised in Part 1; details of rations and weight gains are set out in Part 2. The series of tests began in 1950 and were concluded in 1953. The first was designed simply to study the behaviour of pigs and chicks reared without animal protein. The results showed that the inhibition of growth varied widely from one animal to another and great caution is required in interpreting results. Young animals behave differently from older ones.

The second experiment tested the effect of a syrupy extract of yeast, which contained per kg. 97 μ g. vitamin B₁₂, on the growth of pigs given a ration of cereals, cake meal and minerals with potatoes to appetite. The yeast extract improved growth but not to the same extent as fishmeal. The yeast extract dried with the extracted residue lost most of its effect. In the third experiment, with a similar ration, a small amount of fishmeal was given with the yeast extract but neither that combination nor the fishmeal itself gave good results in this test. In the next test, crystalline vitamin B₁₂ was added to the yeast extract which had been dried on starch. There was no effect of the extra supply.

Experiments 5 and 6 were with day-old chicks kept on a diet of maize meal, soya bean oil meal, minerals, cod liver oil and riboflavin until signs of deficiency appeared. Half were then given the yeast extract with added vitamin B₁₂ and the other half fishmeal. The yeast extract gave the best results. In the last experiment a hydrolysate of yeast with weak acid was compared with a new fungal mycelium rich in vitamin B₁₂, called here O-mycelium, a combination of the two, and crystalline vitamin B₁₂. The last 3 gave much better results than the hydrolysate alone. The combined product, hydrolysed yeast and the new mycelium, have been put on the market under the name Aprofa by Aschaffenburg Zellstoffwerke with a guaranteed vitamin B₁₂ content of 5 mg. per kg. In further tests Aprofa gave as good results as fishmeal.—I. Leitch.

KLINE, E. A., KASTELIC, J., ASHTON, G. C., HOMEYER, P. G., QUINN, L. and CATRON, D. V. The effect on the growth performance of young pigs of adding cobalt, vitamin B₁₂ and antibiotics to semipurified rations. *J. Nutrition*, 1954, 53, 543-555. [Dept. Animal Husb., Iowa State Coll., Ames.]

A semi-purified diet deficient in vitamin B₁₂ and of low cobalt content was given to weanling pigs from sows that had had a maize and soya bean oil meal diet during lactation. Addition of vitamin B₁₂ to the diet significantly increased the rate of weight gain. Co alone did not increase weight gain and did not enhance the effect of vitamin B₁₂. There was no significant effect of Co or vitamin B₁₂ on feed intake or utilisation. If antibiotics, as a mixture of aureomycin, streptomycin, terramycin and penicillin, were added to the diet there was a general improvement in rate of weight gain and in feed utilisation, but the effects of added vitamin B₁₂ were no longer significant.

Microbiological studies of the faeces showed that the bacterial counts were higher in animals given vitamin B₁₂ or Co or both in addition to antibiotics.

The fungus counts were high in pigs given antibiotics and were lower when vitamin B₁₂ was given.—A. M. Copping.

2028

BUYSSE, F. and MARTIN, J. L'emploi d'une préparation à base de vitamine B₁₂, de pénicilline et de procaine dans les aliments composés pour porcs à l'engrais. [The use of a preparation based on vitamin B₁₂ and procaine penicillin in feeds for pig fattening.] *Rev. Agric.*, 1954, 7, pp. 22.

The effect of adding a mixture of vitamin B₁₂ and procaine penicillin to fattening rations containing animal and vegetable protein or vegetable protein alone was studied with 4 groups of 4 pigs during 14 weeks. With 100 mg. of the supplement per kg. ration, growth on a ration chiefly of vegetable products almost equalled that on an animal-protein ration but the feed consumed per unit increase was greater. The cost of the supplemented diet was 19.16 fr. per kg. weight increase in comparison with 16.55 fr. for the normal ration. In a second trial with 6 groups of 4 pigs for 10 weeks and supplements of procaine penicillin with or without vitamin B₁₂, diets with and without 8 per cent. fishmeal were used. No advantage was derived from the supplements with diets containing fishmeal, but with a diet entirely of vegetable products growth was notably improved. The cost of the ration thus supplemented was slightly greater than that of the normal ration. From the nutritional and economic standpoint the supplements did not appear highly efficient.

2030

BENTLEY, O. G., MOINUDDIN, M., HERSHBERGER, T. V., KLOSTERMAN, E. W. and MOXON, A. L. The effect of trace minerals on growth performance and vitamin B₁₂ synthesis of steers. *J. Animal Sci.*, 1954, 13, 789-801. [Ohio Agric. Exp. Stat., Wooster.]

A mixture of trace elements including cobalt, manganese, zinc, iron and copper, or a supplement of alfalfa ash, produced a significant increase in the

average daily weight gains of steers given a ration of mature hay, ground maize, urea, cerelose, calcium, phosphorus, iodised salt and vitamin A. Co appeared to be the first essential trace element and others appeared individually beneficial. The apparent digestibility of the ration was not increased by the trace element mixture.

When Co was given, the amount of vitamin B₁₂ stored in the liver and excreted in the faeces was significantly increased.—A. M. Copping.

2031

SURE, B. Influence of processing on supplementary value of vitamin B₁₂ and amino acids to proteins in whole wheat. *J. Agric. Food Chem.*, 1954, **2**, 1111-1113. [Dept. Agric. Chem., Univ. Arkansas, Fayetteville.]

Young rats grew less well on shredded wheat manufactured from soft wheat than on the original grain. The biological value of the protein of the processed cereal was enhanced by addition of vitamin B₁₂ and amino-acids. The most efficient daily addition was 0.1 µg. vitamin B₁₂ with 0.4 per cent. L-lysine and 0.3 per cent. DL-threonine. The possibility of enriching processed cereals with amino-acids is suggested.—A. M. Copping.

SCHIED, H. E. and SCHWEIGERT, B. S. Vitamin B₁₂ content of organ meats. *J. Nutrition*,

1954, **53**, 419-427. [Div. Biochem. Nutrit., Amer. Meat Inst. Found., Chicago, Ill.]

Vitamin B₁₂ was estimated with *Lactobacillus leichmannii* in liver, heart, kidney, brain, spleen, pancreas and lung tissue of the ox, lamb and pig and in liver from old cows and sows. Satisfactory extraction of the vitamin was obtained by autoclaving for 5 min. and by including thioglycollic acid as a protective agent in the culture medium. The liver and kidney of the ox were the richest sources of vitamin B₁₂, and those of other animals were next in value. Considerable residual vitamin B₁₂ activity was found in pancreas after treatment with alkali when *L. leichmannii* was the test organism, but very little if *Euglena gracilis* was used. The problems involved in the use of alkali treatment to show true vitamin B₁₂ potency are discussed.—A. M. Copping.

NATH, M. C. and CHAKRABARTI, C. H. Biosynthesis of ascorbic acid and prevention of glycogen depletion in liver and muscle. *Proc. Soc. Exp. Biol. Med.*, 1954, 86, 851-854. [Dept. Biochem., Univ. Nagpur, India.]

The intramuscular injection of Na acetoacetate into rats weighing from 100 to 150 g. and given a normal diet increased the concentration of ascorbic acid, estimated by indophenol titration, in the plasma. With a daily injection of 600 mg. per kg. bodyweight the biosynthesis of ascorbic acid was depressed, glycogen in the liver and muscle was depleted and blood sugar rose. In rabbits, 60 mg. per kg. bodyweight caused a slight but temporary increase in plasma ascorbic acid; greater doses had a depressing action. β -Hydroxybutyrate had no effect on the plasma value for ascorbic acid in rats but depressed it in rabbits.

SCHWARTZ, M. A., DE SALEGUI, M. and WILLIAMS, J. N. (Jr.) Effect of dietary aminopterin and sulphasuxidine on biosynthesis of ascorbic acid in the rat. *Proc. Soc. Exp. Biol. Med.*, 1954, 86, 858-862. [Dept. Biochem., Univ. Wisconsin, Madison.]

The destruction of ascorbic acid during incubation with liver homogenates from rats fed on a complete diet including vitamin B_{12} was slightly less when the diet included 4 mg. aminopterin per kg. than when it did not. Aminopterin decreased the concentration of ascorbic acid in the liver (see Abst. 3471, Vol. 21, and for a similar effect with sulphasuxidine Abst. 1717, Vol. 23), adrenal glands and kidneys, and the total amount of ascorbic acid in the spleen. Aminopterin therefore did not cause an abnormally great breakdown of ascorbic acid or promote its translocation from the liver to other organs. Since aminopterin also did not increase the urinary excretion of ascorbic acid (Abst. 434, Vol. 23), the decrease in the rat liver was attributed to inhibition of biosynthesis. Experiments with guineapigs receiving adequate ascorbic acid supported the theory, since aminopterin and sulphasuxidine did not depress the amount of ascorbic acid in the liver. Sulphasuxidine is poorly absorbed through the intestinal wall and is a bacterial inhibitor like aminopterin. It was thought possible that the 2 substances depressed liver ascorbic acid by the inhibition of intestinal micro-organisms which produce some necessary compounds of the system for synthesis of ascorbic acid.—A. Hepburn.

2044

ERSHOFF, B. H. Protective effects of alfalfa in immature mice fed toxic doses of glucoascorbic acid. *Proc. Soc. Exp. Biol. Med.*, 1954, 87, 134-136. [Dept. Biochem. Nutrit., Univ. S. California, Los Angeles.]

Immature mice fed on a diet containing all the known vitamins and 4 per cent. glucoascorbic acid lost weight and had diarrhoea, an unthrifty appearance, irritation and swelling of the anal region, and alopecia. Dried alfalfa as 10 per cent. of the diet completely cured the mice but alfalfa ash, more of some of the same vitamins, casein or cottonseed oil had no effect. Purified cellulose as 12 per cent. of the diet effected a cure also, but the weight increase was significantly less than with dried alfalfa.—A. Hepburn.

SCHMIDT, H. Untersuchungen zur Bestimmung des Ovulationstermines mit dem Vitamin C-Test bei Haustieren. [Estimation of the time of ovulation by the vitamin C test in domestic animals.] *Ztschr. Tierzücht. Züchtungsbiol.*, 1954, **63**, 303-328. [Inst. Tierzücht., Tech. Univ. Berlin, Charlottenburg.]

The method is based on the clinical findings that after a daily test dose women retain vitamin C with a maximum 15 days before menstruation (Pillay [no reference]) or at 2 different points in the cycle (Rusca, *Diss.*, Berne, 1947), of which one is thought to correspond with ovulation. Parallel experiments were made with 10 cows, 2 ewes, 2 goats and 2 sows; the cattle and sows were given 0.5 mg. ascorbic acid per kg. liveweight and the ewes 1 mg. per kg. by intramuscular injection daily in the early morning. Four hr. later, urine was collected. In comparison with control values, excretion of vitamin C rose at once and remained high and fairly steady except for a sharp dip about or just after the termination of heat in the ruminants, and one or more equally sharp dips in the sows in which oestrus persisted for a few days.—I. Leitch.

Vol. 26, No. 2

[Lab. Biol. Méd., Fac. Méd., C.N.R.S., Hautes-Études, Paris.]

In guinea pigs fed on a scorbutogenic diet, the water-soluble corticosteroids in the adrenal glands decreased progressively with the content of ascorbic acid for about the first 28 days while the deficiency was acute. In animals which survived into a chronic phase the content of corticosteroids rose again, while the adrenal glands hypertrophied. Paper chromatography showed that the corticosteroids present in scurvy differed qualitatively from those in the normal adrenal gland.

FORBES, J. C. and DUNCAN, G. M. Effect of intraperitoneal administration of alcohol on the adrenal levels of cholesterol and ascorbic acid in rats and guinea pigs. Effect of vitamin C intake on the adrenal response of rats and guinea pigs to alcohol administration. *Quart. J. Studies Alcohol.*, 1953, **14**, 19-21; 22-27. [Biochem. Dept., Med. Coll. Virginia, Richmond.]

Adult rats were injected intraperitoneally with 3 g. ethanol per kg. bodyweight as a 10 per cent. solution in 5 per cent. glucose or in 0.85 per cent. saline. From 4 to 5 hr. later the animals were killed and ascorbic acid was estimated in one adrenal gland by the method of Roe and Kuether (Abst. 261, Vol. 13), and cholesterol by the method of Outhouse and Forbes (Title 2308, Vol. 10) in the other. In rats given glucose or saline without alcohol, the values for ascorbic acid and cholesterol were higher with saline than with glucose. All values for rats given alcohol were lower than for rats not given it. The results were confirmed with guinea pigs.

Male guinea pigs weighing from 200 to 280 g., maintained on a stock diet, were given by stomach tube a 50 per cent. solution of 95 per cent. ethanol, supplying between 5 and 7 g. absolute alcohol per kg. bodyweight. Some animals, both given and not given alcohol, were injected intraperitoneally with 50 mg. Na ascorbate just before the administration of alcohol. Most of the animals were killed 24 hr. later, but in some the procedure was repeated several times. The adrenal glands were analysed as described above. The single injection of Na ascorbate did not prevent the fall in ascorbic acid or cholesterol content of the adrenal glands, but the repeated injections promoted the return of both values to normal.

In further experiments with rats and guineapigs, intraperitoneal injections of 50 or 75 mg. Na ascorbate per 100 g. bodyweight were given daily for 3 days before administration of alcohol, but failed to prevent the fall in adrenal ascorbic acid and cholesterol ensuing from administration of alcohol.—E. M. Hume.

BERGERON, G. A., BOURBEAU, G. and LAMARRE, C. J. Effets de l'acide ascorbique, de la cortisone et de la surrénalectomie sur l'hypertension expérimentale à la DCA. [Effect of ascorbic acid, cortisone and adrenalectomy on experimental hypertension caused by DCA.] *Rev. canad. Biol.*, 1954, 13, 106-114. [Dept. Physiol., Laval Univ., Quebec.] English summary.

In 74 male rats weighing about 88 g., from which the adrenal glands had been removed, hypertension was induced by removal of one kidney. The rats were fed on Purina cubes with NaCl solution to drink. Three groups were formed of which 2 received for 14 days a daily injection of 2.5 mg. deoxycorticosterone acetate (Ciba), one with and one without addition of 4 doses of 40 mg. Na ascorbate daily, and the third received no further treatment. Arterial blood pressure was measured under ether anaesthesia. In the group not given deoxycorticosterone acetate there was a small increase of blood pressure. In the 2 groups given it there was a considerable rise in blood pressure which was not significantly less when ascorbic acid also was given. The blood pressure was still high a week after withdrawal of deoxycorticosterone acetate. The weight curve showed that ascorbic acid did not mitigate the oedema caused by deoxycorticosterone acetate. It thus appeared that ascorbic acid did not exercise its known effect to counteract the effect of deoxycorticosterone acetate unless the adrenal glands were intact.

In another experiment with 5 groups of 15 or 16 intact rats, cortisone was given to 4 groups, alone, or with ascorbic acid, or with deoxycorticosterone acetate, or with both. One group received deoxycorticosterone acetate only. There was much mortality from intercurrent diseases, which was not less with ascorbic acid. Blood pressure rose with cortisone or deoxycorticosterone acetate or both, and ascorbic acid had no counteracting effect. On withdrawal of cortisone after 14 days, blood pressure began to drop but was maintained on withdrawal of deoxycorticosterone acetate.

MILKOVIĆ, S. Influence of vitamin C on the extra-adrenal effect of ACTH. *Arch. internat. Physiol.*, 1954, 62, 309-312. [Dept. Pharmacol., Med. Fac., Univ. Zagreb.]

Male rats were castrated and had their adrenal glands removed; some of them received injections of adrenocorticotrophic hormone with and some without ascorbic acid. The thymus and preputial glands were weighed after 7 days and compared with those from a group of normal rats. Adrenalectomised rats and those receiving hormone had significantly greater thymus weights. When ascorbic acid was given with the hormone there was no increase in the thymus weight, the effect of the hormone being inhibited. Adrenalectomy alone or with the hormone did not affect the weight of the preputial glands, but the hormone with ascorbic acid produced a significant increase.

MARRUBINI, G. and GUANZIROLI, B. Azione degli estrogeni sul contenuto in acido ascorbico dei surreni del ratto ipofisectomizzato. [Action of oestrogens on the ascorbic acid content of the adrenal glands of hypophysectomised rats.] *Arch. Fisiol.*, 1954, 54, 1-5. [Ist. Fisiol. Gen., Univ. Milan.]

The pituitary glands were removed from 2 groups of 10 rats weighing about 100 g. Twenty-four hr. later, the left adrenal gland was removed from each animal, and 0.1 or 0.3 mg. oestradiol benzoate was injected intraperitoneally in the 2 groups, respectively. The second adrenal gland was removed 1½ hr. later, and ascorbic acid was estimated in both glands by the method of Roe and Knether (Absts. 261, Vol. 13; 1225, Vol. 14). Two other groups of 10 intact rats received the same treatment.

The mean content of ascorbic acid in the adrenal glands was not affected by the injection of oestrogen in the rats without pituitary glands, but in intact rats the mean value, in µg. per mg., was reduced from 4.005 to 3.422 and from 3.356 to 2.325, with the smaller and the larger dose, respectively.

KATSH, S., KATSH, G. F. and OSHER, P. Adrenal, pituitary and urinary ascorbic acid levels in rats subjected to hypothermic environment. *Amer. J. Physiol.*, 1954, 178, 457-461. [Kerekhoff Labs. Biol., California Inst. Technol., Pasadena.]

Adult male rats fed on a diet deficient in vitamin C were maintained at room temperature as controls or in the cold (2° to 4° C.). In the rats subjected to cold the weight of the adrenal glands and their total content of ascorbic acid increased, the latter by 60 and 20 per cent. of the values for the controls after 10 and 28 days, respectively. The average concentration of ascorbic acid in the adrenal glands fell below the values for the controls after 10 days. Bodyweight first fell, but then rose to approach the weight of the controls after 12 days.

N.A. and R., April 1955

The increase in total ascorbic acid was believed to be the response to the cold stress with consequent greater activity and hypertrophy of the adrenal glands.

The ascorbic acid content of the pituitary, which was less in the cold than at room temperature, rose to about normal after 10 days, and then became still greater after 28 days. Concentration of vitamin C in the urine decreased in the cold but the volume of urine increased so that the amounts excreted in 24 hr. changed little.—A. Hepburn.

HASSAN, H. H. and MCCOLLUM, J. P. **Factors affecting the content of ascorbic acid in tomatoes.** *Illinois Agric. Exp. Stat. Bull.* No. 573, April 1954, pp. 24. [Urbana, Ill.]

Tomatoes exposed to direct sunlight contained significantly more ascorbic acid than those shaded. The effect of sunshine was evidently cumulative, as the maximum content of ascorbic acid was not attained if the tomatoes had been shaded for part of the time during development. By selecting tomatoes according to the extent of light exposure, the sampling error could be greatly reduced and more accurate comparisons could be made of tomatoes exposed to direct sunlight. The difference amounted to from 2 to 3 mg. ascorbic acid per 100 g. fresh fruit from samples of 10 fruits. Two varieties of exposed tomatoes had a peak in the content of ascorbic acid about the middle of the season, and also a greater seasonal variation than shaded ones. Varieties of tomato may vary in time of maturity, so shaded fruits should be used for comparison at different times during the season.

The uppermost tomatoes from greenhouse plants contained most ascorbic acid. Thinning to 2 tomatoes per truss caused an increase in the ascorbic acid content.—A. Hepburn.

2056

FRATONI, A. and SPADONI, M. A. Contributo allo studio dell'influenza della concimazione sul contenuto in acido ascorbico dei pomodori. [Effect of fertilisers on the ascorbic acid content of tomatoes.] *Quad. Nutrizione*, 1953, 13, 52-60. [Ist. Naz. Nutrizione C.N.R., Rome.]

Groups of 6 plants of *Lycopersicon esculentum* var. *pyriformis* were transferred from ordinary soil to pots of the same soil to which were added on 11 July superphosphates or Ca nitrate or both or neither. Fruit ripened in August, and was gathered as soon as the colour was wholly red. Ascorbic acid was estimated by indophenol titration with use of metaphosphoric acid for extraction in the first 2 fruits on each plant, and the

whole crop from each plant was weighed. The results were analysed statistically. None of the fertilisers had any influence on the concentration of ascorbic acid in the fruits. The total amount in individual fruits was somewhat increased by superphosphates and decreased by nitrates; the two together tended to counteract one another.

2057

MURPHY, E. F. **Vitamin C content of Maine rutabagas.** *Maine Agric. Exp. Stat. Bull.* No. 508, January 1953, pp. 16. [Orono, Maine.]

The ascorbic acid content of 10 varieties of fresh rutabaga ranged from 40.8 to 55.9 mg. per 100 g. during one season. Differences within the same varieties during the same season were from 4.8 to 11.2 mg. and the averages for 2 varieties over 3 successive crop years were 37.8, 47.6 and 39.1 mg. per 100 g. Application of commercial fertiliser, farm manure, borax or lime did not influence the ascorbic acid content. Small rutabagas contained more ascorbic acid than large ones.

Loss of ascorbic acid was negligible on storage at 32°, 34° and 40° F. and in some cases the amount increased but no account was taken of possible loss of weight. Quality was superior at the 2 lower temperatures. Cooking in small amounts of initially boiling water caused a loss of less than 30 per cent. ascorbic acid, but more than 50 per cent. was lost with long cooking started in cold water.—A. Hepburn.

PETUELY, F. and LYNAU, V. Ein einfacher, voll-synthetischer Optimalnährboden für den *Lactobacillus bifidus*. (Über die Bedeutung der Ascorbinsäure für das Wachstum des *Lactobacillus bifidus*.) [Simple, completely synthetic, optimum nutrient medium for *Lactobacillus bifidus*. (Significance of ascorbic acid for the growth of *Lactobacillus bifidus*.)] *Biochem. Ztschr.*, 1954, 326, 62-78. [Universitätsplatz 2, Graz.]

The synthetic nutrient medium previously devised for growing *Lactobacillus bifidus* (*Biochem. Ztschr.*, 1952, 322, 463) was further developed and improved. The solution finally adopted which at pH 6.4 gave optimum growth for all the strains investigated, obtained from the stools of breast-fed infants, was a fully synthetic medium, containing ammonium sulphate or acetate as the only source of N. Substances shown to be essential were cystine, Ca pantothenate, some salts, and phosphate, which was supplied as primary K

phosphate. Optimum growth was obtained with the addition of from 1 to 2.5 per cent. ascorbic acid, which acted as a buffer, but could not be replaced by phosphate or acetate buffer. The mechanism of its growth-promoting action presumably lay in the maintenance of a definite oxidation-reduction potential. Biotin was necessary only if the ascorbic acid content was 0.5 per cent. or less, and it could generally be replaced by Tween 80. With 1 per cent. ascorbic acid or more, biotin or Tween 80 was not essential for optimum growth. With 2 per cent. agar the same formula could be used as a solid nutrient medium. The composition of the complete nutrient solution at pH 6.4 was, per 100 ml., lactose 3.5 g., ammonium sulphate or acetate 0.2 g., cystine 0.02 g., K_2HPO_4 0.25 g., $MgSO_4 \cdot 7H_2O$ 12.5 mg., $FeSO_4 \cdot 7H_2O$ 0.6 mg., $MnSO_4 \cdot 2H_2O$ 0.4 mg., NaCl 0.6 mg., Ca pantothenate 20 μ g., L-ascorbic acid 2 g., and at times biotin 0.2 μ g. or Tween 80 0.1 g.

MOSES, C. The effect of phosphorylated hesperidin on experimental atherosclerosis. *Amer. Heart J.*, 1954, 48, 264-265. [Addison H. Gibson Lab., Sch. Med., Univ. Pittsburgh, Pa.]

Phosphorylated hesperidin has an effect antagonistic to hyaluronidase.

Male rabbits were maintained on a diet of Purina rabbit chow on which 5 g. cholesterol dissolved in ether was poured 3 times a week. Groups of from 8 to 16 were given intraperitoneally per kg. bodyweight 40 mg. phosphorylated hesperidin five times a week for 4 weeks, or 50 mg. three times a week for 4 weeks, or 100 mg. three times a week for 8 weeks, or sterile saline three times a week for 4 or 8 weeks. Weight gain was irregular, being adversely affected by hesperidin, and development of atherosclerosis was directly related to weight gain. The groups given hesperidin had less atherosclerosis than one of the groups given saline which increased considerably in weight, but had about the same degree as the other group given saline, which increased less in weight. No protective action of hesperidin was thus demonstrated.

DE FILIPPI, F., GIUSSANI, A. A. and RIVELIS, L. Assay of the tryptic activity of the feces of the newborn infant, at term or premature. *Pediatrics*, 1954, 14, 114-116. [Hosp. Clin., Buenos Aires.] Spanish summary.

The tryptic activity of faeces of 30 newborn children, 4 of whom were premature, was measured. In 28 no trypsin was detected on the first day of life, but by the fourth day specimens from all infants were positive. Since duodenal contents in the foetus are known to possess activity it is concluded that its absence from faeces is the result of intestinal stagnation, and that in suspected meconium ileus the estimation has no diagnostic value.

SEIGE, K. Zur biologischen Wertigkeit der Kohlenhydrate. 1. Über enzymatischen Abbau von Weizenmehl durch menschliche Fermente. [Biological value of carbohydrates. 1. Enzymic breakdown of wheat flour by human enzymes.] 2. Vergleichender enzymatischer Abbau verschiedener Mehle durch menschliche Fermente. [2. Comparative enzymic breakdown of different flours by human enzymes.] *Deutsch. Ztschr. Verdauungs- u. Stoffwechsellehr.*, 1954, 14, 180-187; 224-233. [Med. Klin., Univ. Leipzig.]

1. Finely ground wheat flour of known composition was boiled with water for 5 min. under reflux, cooled to 38° C. and mixed with human fasting duodenal juice, and starch breakdown products with free aldehyde groups were estimated at intervals by the Hagedorn Jensen method. By

varying the proportions it was possible to obtain a linear relation between the percentage of the starch broken down and the time elapsed, which could serve as a standard for comparison.

2. Similar experiments were made with rye, oats, barley, rice, maize and potatoes. Breakdown of wheat starch was significantly slower and that of potato starch significantly faster than for the other cereals, which did not differ significantly among themselves.

In a discussion of the possible clinical applications, it is suggested that wheat starch might suit patients with labile blood sugar and potato starch those deficient in duodenal enzymes; but for definite information experiments *in vivo* are essential.—W. M. Deans.

MELCHIOR, J. B. and SLIWINSKI, R. A. Proteolytic inhibitors in serum. 1. Effect of food intake and of hypophysectomy. *Cancer Res.*, 1954, 14, 677-681. [Dept. Biochem., Grad. Sch., Loyola Univ., Chicago, Ill.]

The inhibitory effect of serum was studied *in vitro* with solutions of crystalline trypsin and chymotrypsin digesting casein. Chymotrypsin was more easily estimated.

When rats were fasted until they lost a third of their initial bodyweight the inhibitory effect of their serum was not changed. After pituitary removal the effect was significantly reduced, and this was reversed when the rats received injections of pituitary homogenate. Growth hormone increased the inhibitory effect of serum when it was injected, but not when it was added to the protein-digesting system *in vitro*.—D. Duncan.

2069

SIRCUS, W. Studies of uropepsinogen excretion in gastrointestinal disorders. *Quart. J. Med.*, 1954, **23**, 291-306. [Royal Infirmary, Sheffield.]

With a substrate made from dried human plasma, the excretion of uropepsinogen was measured in 256 subjects, 61 normal controls and the others with gastro-intestinal disorders.

The mean output of uropepsinogen was abnormally high in patients with duodenal ulcer and those with haematemesis in whom the existence of a duodenal ulcer was subsequently disclosed. Output was abnormally low in Fe-deficiency anaemia and pernicious anaemia. Mean output was normal in patients with gastric ulcer and in dyspepsia not due to disease in the digestive tract. No uropepsinogen was excreted by patients who had undergone total gastrectomy or by most of those who had undergone partial gastrectomy. Patients who had carcinoma of the stomach excreted less uropepsinogen than normal subjects, but this was not of diagnostic value.

The measurement of uropepsinogen is thought to be of value in clinical investigation and in research on the digestive processes.—F. C. Aitken.

2070

VIJAYARAGHAVAN, P. K. and NARASINGA RAO, B. S. The influence of duck egg white (DEW) ovomucoid on the liberation of essential amino acids from different proteins by trypsin *in vitro*. *Indian J. Med. Res.*, 1954, **42**, 373-379. [Nutrit. Res. Labs., Indian Coun. Med. Res., Coonoor, S. India.]

Solutions of casein, wheat gluten, Bengal gram globulin, coagulated hen egg white and autoclaved duck egg white in phosphate buffer were digested with trypsin, and the effect of duck ovomucoid on the release of total amino-N and essential amino-acids was estimated after 24 and 120 hr.

The release of total amino-N was significantly inhibited and was least from casein and wheat gluten. The release of amino-acids, in particular histidine, lysine and threonine, was also inhibited with every protein, most with Bengal gram globulin and least with casein.

The antitryptic activity of the ovomucoids from duck and hen on casein was about the same, but after 24 hr. the activity of hen ovomucoid was much less than that of duck ovomucoid and after 120 hr. it had disappeared.

The growth-depressing action of duck ovomucoid was attributed to a possible block in the supply of essential amino-acids for formation of tissue protein.—A. Hepburn.

2071

STARK, G. and SIEBERT, G. Kathepsinaktivität in Placenten verschiedener Altersstufen. [Cath-

epsin activity in placentas of different ages.] *Arch. Gynäkol.*, 1954-55, **185**, 50-59. [Frauenklinik, Univ. Mainz.]

Cathepsin activity was estimated in placentas at intervals during pregnancy. For statistical purposes the results were arranged in 3 groups: months 2 to 6, 24 placentas; months 7 to 10, 28; and a group of 6 beyond term. The values for cathepsin activity, expressed as μg . tyrosine per mg. N per hr., were 112, 61 and 19, respectively. There was thus a definite fall of activity in the later months of pregnancy, the differences being statistically significant. The significance of the enzyme in the placenta for growth is discussed.

2072

LACOBELLIS, M., MUNTWYLER, E. and GRIFFIN, G. E. Enzyme concentration changes in the kidneys of protein- and/or potassium-deficient rats. *Amer. J. Physiol.*, 1954, **178**, 477-482. [Dept. Biochem., Coll. Med., State Univ. New York, Brooklyn.]

Young adult rats received diets low in K or protein or both, as described in Absts. 3842, Vol. 20 and 831, Vol. 24.

The kidneys increased in weight on the low-K diet and decreased with low protein or low K and protein. Kidney N per g. fresh tissue remained constant except on the low-protein diet. Changes in D-amino-acid oxidase and arginase were related to the changes in total kidney N. Changes in glutaminase and carbonic anhydrase were not great; their increases on the low-K diet and falls on the low-K, low-N diet were directly related to changes in ammonia excretion and urinary total acidity.

No explanation is offered.—D. Duncan.

2073

VAN REEN, R. The influence of excessive dietary molybdenum on rat liver enzymes. *Arch. Biochem. Biophys.*, 1954, **53**, 77-84. [McCullum Pratt Inst., Johns Hopkins Univ., Baltimore, Md.]

Young rats received a purified diet containing 400 to 1200 p.p.m. Mo for 4 or 5 weeks. Enzyme activity in the liver was then studied.

No significant effect of Mo was found on cytochrome oxidase, catalase, isocitric dehydrogenase or diphosphopyridine nucleotidase, but alkaline phosphatase was as much as 9 times the control value in rats given 1200 p.p.m. Mo. Hb was not greatly affected. Inorganic P in liver homogenates was not affected by Mo. No inhibitor or activator of alkaline phosphatase was found, and it was believed that there was a higher concentration of the enzyme in rats given Mo. Growth and

N.A. and R., April 1955

food intake were depressed by Mo, but the effect on alkaline phosphatase was shown by paired feeding to be real.—D. Duncan.

MONDY, N. I., STRENGTH, D. R., GRAY, L. F. and DANIEL, L. J. Effect of age of rat on choline oxidation *in vitro*. *Proc. Soc. Exp. Biol. Med.*, 1954, **87**, 129-131. [Dept. Biochem. Nutrit., Cornell Univ., Ithaca, N.Y.]

Diphosphopyridine nucleotide (DPN), choline dehydrogenase and betaine aldehyde dehydrogenase were estimated manometrically in livers from rats aged 2 days, 1, 2, 3, 5, 7, 9 and 13 weeks and 11 months. DPN and choline dehydrogenase at 2 days were 21.9 and 25.6 per cent. of the adult values. Increases to 94.8 and 85.0 per cent. were obtained after 9 and 13 weeks. Betaine aldehyde dehydrogenase was 90.7 per cent. at 2 days. The low rate of choline oxidation in liver from young rats was probably due to lack of choline apodehydrogenase.—A. Hepburn.

SIRCUS, W. Studies of uropepsinogen excretion in gastrointestinal disorders. *Quart. J. Med.*, 1954, 23, 291-306. [Royal Infirmary, Sheffield.]

With a substrate made from dried human plasma, the excretion of uropepsinogen was measured in 256 subjects, 61 normal controls and the others with gastro-intestinal disorders.

The mean output of uropepsinogen was abnormally high in patients with duodenal ulcer and those with haematemesis in whom the existence of a duodenal ulcer was subsequently disclosed. Output was abnormally low in Fe-deficiency anaemia and pernicious anaemia. Mean output was normal in patients with gastric ulcer and in dyspepsia not due to disease in the digestive tract. No uropepsinogen was excreted by patients who had undergone total gastrectomy or by most of those who had undergone partial gastrectomy. Patients who had carcinoma of the stomach excreted less uropepsinogen than normal subjects, but this was not of diagnostic value.

The measurement of uropepsinogen is thought to be of value in clinical investigation and in research on the digestive processes.—F. C. Aitken.

2070

VIJAYARAGHAVAN, P. K. and NARASINGA RAO, B. S. The influence of duck egg white (DEW) ovomucoid on the liberation of essential amino acids from different proteins by trypsin *in vitro*. *Indian J. Med. Res.*, 1954, 42, 373-379. [Nutrit. Res. Labs., Indian Council Med. Res., Coonoor, S. India.]

Solutions of casein, wheat gluten, Bengal gram globulin, coagulated hen egg white and autoclaved duck egg white in phosphate buffer were digested with trypsin, and the effect of duck ovomucoid on the release of total amino-N and essential amino-acids was estimated after 24 and 120 hr.

The release of total amino-N was significantly inhibited and was least from casein and wheat gluten. The release of amino-acids, in particular histidine, lysine and threonine, was also inhibited with every protein, most with Bengal gram globulin and least with casein.

The antitryptic activity of the ovomucoids from duck and hen on casein was about the same, but after 24 hr. the activity of hen ovomucoid was much less than that of duck ovomucoid and after 120 hr. it had disappeared.

The growth-depressing action of duck ovomucoid was attributed to a possible block in the supply of essential amino-acids for formation of tissue protein.—A. Hepburn.

2071

STARK, G. and SIEBERT, G. Kathepsinaktivität in Placenten verschiedener Altersstufen. [*Cath-*

epsin activity in placentas of different ages.] *Arch. Gynäkol.*, 1954-55, 185, 50-59. [Frauenklinik, Univ. Mainz.]

Cathepsin activity was estimated in placentas at intervals during pregnancy. For statistical purposes the results were arranged in 3 groups: months 2 to 6, 24 placentas; months 7 to 10, 28; and a group of 6 beyond term. The values for cathepsin activity, expressed as μ g. tyrosine per mg. N per hr., were 112, 61 and 19, respectively. There was thus a definite fall of activity in the later months of pregnancy, the differences being statistically significant. The significance of the enzyme in the placenta for growth is discussed.

IACOBELLIS, M., MUNTWYLER, E. and GRIFFIN, G. E. Enzyme concentration changes in the kidneys of protein- and/or potassium-deficient rats. *Amer. J. Physiol.*, 1954, 178, 477-482. [Dept. Biochem., Coll. Med., State Univ. New York, Brooklyn.]

Young adult rats received diets low in K or protein or both, as described in Absts. 3842, Vol. 20 and 831, Vol. 24.

The kidneys increased in weight on the low-K diet and decreased with low protein or low K and protein. Kidney N per g. fresh tissue remained constant except on the low-protein diet. Changes in p-amino-acid oxidase and arginase were related to the changes in total kidney N. Changes in glutaminase and carbonic anhydrase were not great; their increases on the low-K diet and falls on the low-K, low-N diet were directly related to changes in ammonia excretion and urinary total acidity.

No explanation is offered.—D. Duncan.

2073

VAN REEN, R. The influence of excessive dietary molybdenum on rat liver enzymes. *Arch. Biochem. Biophys.*, 1954, 53, 77-84. [McCollum Pratt Inst., Johns Hopkins Univ., Baltimore, Md.]

Young rats received a purified diet containing 400 to 1200 p.p.m. Mo for 4 or 5 weeks. Enzyme activity in the liver was then studied.

No significant effect of Mo was found on cytochrome oxidase, catalase, isocitric dehydrogenase or diphosphopyridine nucleotidase, but alkaline phosphatase was as much as 9 times the control value in rats given 1200 p.p.m. Mo. Hb was not greatly affected. Inorganic P in liver homogenates was not affected by Mo. No inhibitor or activator of alkaline phosphatase was found, and it was believed that there was a higher concentration of the enzyme in rats given Mo. Growth and

food intake were depressed by Mo, but the effect on alkaline phosphatase was shown by paired feeding to be real.—D. Duncan.

TUBA, J. and DICKIE, N. The role of alkaline phosphatase in intestinal absorption. 2. The effects of various carbohydrates on levels of the enzyme in intestinal mucosa. *Canad. J. Biochem. Physiol.*, 1954, **32**, 621-624. [Dept. Biochem., Univ. Alberta, Edmonton.]

See also Abst. 565, Vol. 24.

Adult rats after being fed on stock diet were fasted for 5 days. Groups of from 5 to 7 then received 5 g. cellulose or 3.5 g. cellulose mixed with 1.5 g. digestible carbohydrate. They were killed 6 hr. later for estimation of intestinal alkaline phosphatase.

Glucose, galactose, fructose and mannose significantly increased the amount of phosphatase; cellulose, sucrose, arabinose and xylose did not. The results support the view that alkaline phos-

phatase may participate in the absorption of some sugars.—D. Duncan.

PATHAK, J. D., PAI, M. L. and GANDHI, A. M. **Gastric response, digestion and evacuation time of some milk preparations.** *Indian J. Med. Res.*, 1953, **41**, 17-25. [Dept. Physiol., Med. Coll., Baroda.]

The subjects were healthy adult students. The preparations, given by stomach tube, were: boiled milk, with or without sugar, ice-cream, unsweetened condensed milk; curds, non-sour; chhas (curds with added water and salt); maska (non-sour curds from which water is expressed); shrikhand (maska mixed with sugar); mava (evaporated milk); basundi (sweetened evaporated milk); dudhpak (sweetened evaporated milk, cooked with a small amount of rice); cheese.

Protein digestion began in about 15 min. after administration of the foods. Boiled milk, with or without sugar, and ice-cream evoked less secretion of acid than the other preparations and left the stomach more rapidly.—F. C. Aitken.

2087

HUNT, J. N. **The inhibitory action of sucrose on gastric digestive activity in patients with peptic ulcer.** *Guy's Hosp. Rep.*, 1954, **103**, 161-173. [Dept. Physiol.]

A method for the simultaneous assessment of gastric emptying and secretion is described and the computation of parietal cell secretion is shown. Non-parietal secretions were obtained by difference between total and parietal components of gastric secretion. Responses to test meals of 1750 ml. water alone or containing 35 to 100 g. sucrose per litre, with phenol red, were studied in 5 normal men, 5 men with duodenal ulcer and 3 men with gastric ulcer. In all 3 groups volume of gastric contents at 30 min. rose with increasing concentration of sucrose in the test meal. Four of 5 patients with duodenal ulcer, 2 of 5 normal subjects and none of the 3 gastric ulcer patients showed a decreased secretion of the acid component when the concentration of sucrose in the meal was raised to 100 g. per litre. Between the normal subjects there was little variation in non-parietal secretion, and this component was not affected by alteration in the concentration of sucrose in the test meal. Between subjects with peptic ulcer there was considerable

variation in non-parietal secretion and this component was influenced by sucrose intake.

McCORKLE, H. J. and HARPER, H. A. **The problem of nutrition following complete gastrectomy.** *Ann. Surg.*, 1954, **140**, 467-473 (with discussion 473-474). [Div. Surg., Univ. California Sch. Med., San Francisco.]

Results are summarised of nutrition studies of 120 dogs after total gastrectomy. Normal dogs and dogs after partial gastrectomy were controls. "Alimentation time" after total gastrectomy decreased to less than half that of normal controls. Absorption of amino-acids was quicker but efficiency of absorption was less than in controls. Most animals remained in positive N balance after total gastrectomy. Absorption of glucose was quicker, but there was a more rapid fall in blood sugar levels in the experimental animals. Rate of fat absorption was somewhat increased. Supplements of HCl, intrinsic factor, vitamin B₁₂ and an antibiotic were given to prevent diarrhoea and anaemia. There was little diarrhoea, but microcytic hypochromic anaemia occurred. It is suggested that larger amounts of vitamin B₁₂ might have controlled the anaemia.

Weight loss was least in dogs with oesophago-duodenostomy and greatest in those with colon transplants. Nutrition was better maintained in dogs trained to eat little and often.

The implications for management of human subjects are indicated.—F. C. Aitken.

OTTO, W. **Über die Verdauung des Sumpfbibers (*Myocastor coypus*). [Digestion in the nutria (*Myocastor coypus*).]** *Arch. Tierernährung*, 1954, **4**, No. 4, Beihefte, 119-150. [Anst. Vitaminforsch., Potsdam, Rehbrücke.]

N.A. and R., April 1955

Eighteen nutrias were studied in captivity. Their diet in summer consisted largely of green plants, especially *Galinsoga parviflora*, *Oenothera biennis* and clover. They also liked potatoes cooked in their skins, carrots or turnips and branches to gnaw, windfalls and maize stalks. In winter they ate carrots, turnips, potatoes and bread. They preferred roots to green plants and liked to gnaw wood. Nearly all food was taken to the pond and washed before being eaten.

Faeces were deposited in the water. Coprophagy was not seen for certain, and no faecal remains were found in the stomach.

The anatomy of the digestive tract is described. There is a large stomach, with well-defined cardiac, fundic and pyloric regions but no non-secretory portion like that in the rat. Digestion was studied and also the movements of the stomach and the bacterial flora of the tract. The digesta tend to have a high water content.—D. Duncan.

Vol. 25, No. 2

4. The Na salts of the fatty acids tested were injected into the jugular vein of sheep with a rumen fistula, as 20 ml. of an aqueous solution containing from 0.5 to 10 cg. per kg. bodyweight.

Na acetate in a dose of 10 cg. per kg. bodyweight caused an immediate decrease in the amplitude of rumen contractions, which lasted for from 6 to 8 min.; the rhythm then became normal again, but from 40 to 65 min. after the injection the amplitude was again decreased and the rate was slowed for 2 or 3 hr.

Injection of 10 cg. per kg. bodyweight of Na propionate or Na butyrate also had an inhibitory effect which was complete at first for some minutes, and then pursued a varying course.

Less than 10 cg. of any of the substances produced much smaller effects.

5. Graphs are shown of the rumen contractions during rumination and of the behaviour of the rumen and reticulum during sleep. The results are discussed with those of others, and it is suggested that there is an analogy between the functioning of the respiratory centre and that of the centre controlling the motility of the rumen and reticulum.—E. M. Hume.

HELLER, H. Intestinal absorption of glucose in protein-deficient and in starving rats. *Brit. J. Nutrition*, 1954, 8, 370-379. [Dept. Pharmacol., Univ. Bristol.]

Groups of rats received a control diet with 18 per cent. casein; a low-casein, high-carbohydrate diet with 0.5 per cent. casein; a vegetable

low-protein diet with 81.5 per cent. turnip; or a wet filter-paper diet with 0.8 per cent. casein. After a test dose of glucose by stomach tube, the amount of glucose remaining in the stomach after 42 min. was more in the protein-deficient rats than in the controls, and the amount of glucose absorbed from the intestine was less. Rats starved for 48 to 96 hr. showed a normal or increased gastric emptying time and the relative amount absorbed from the intestine was decreased. Glucose tolerance curves in the protein-deficient rats and those starved for 48 hr. were normal; rats starved 96 hr. showed an exaggerated hyperglycaemic response. There was no histologically demonstrable abnormality in the small intestine.—C. Warner.

2098

MATTHEWS, D. M. and SMYTH, D. H. **The intestinal absorption of amino-acid enantiomorphs.** *J. Physiol.*, 1954, **126**, 96–100. [Dept. Physiol., Univ. Sheffield.]

The DL-form of alanine, phenylalanine or leucine was injected into the lumen of an isolated loop of the intestine of a cat and the D- and L-amino-acids were estimated separately at intervals in the vein draining that part of the intestine. The L:D ratios of the absorbed amino-acids were roughly 5, 2 and 3, respectively. When the temperature of the gut was lowered, the L:D ratio for alanine tended to approach unity; similar results were obtained *in vitro*.—C. Warner.

BERGSTROM, S., BORGSTROM, B. and CARLSTEN, A. **On the mechanism of intestinal fat absorption in the cat.** *Acta physiol. scand.*, 1954, **32**, 94–98. [Dept. Physiol. Chem., Univ. Lund.]

Maize oil with stearic acid- $1^{14}C$, maize oil transesterified with labelled stearic acid or hydrolysed maize oil with labelled stearic acid was given to unanaesthetised cats with their main intestinal lymphatics cannulated. Lymph was then collected for from 10 to 17 hr.; lymph lipids were fractionated and the fatty acids of phospholipids

and glycerides were isolated for estimation of their radio-activity.

The results, which amplify those previously obtained with anaesthetised cats (Abst. 5408, Vol. 20), showed that there was no difference in the route of absorption of labelled stearic acid whether it was in combination as glyceride or dissolved in free fatty acids. The distribution of the stearic acid among lymph glycerides and phospholipids showed that extensive hydrolysis and randomisation had occurred.—G. A. Garton.

In 8 normal subjects radio-activity was detected in the hand within $2\frac{1}{2}$ min. after $^{24}NaCl$ was injected into the duodenum. The count increased rapidly thereafter. In 6 out of 8 patients with tropical sprue and 6 out of 7 with idiopathic steatorrhoea there was a delay in the initial hand count and a slower than normal rise thereafter. The exceptions were the least severely affected. Two patients with tropical sprue tested before and after clinical recovery showed return to normal counting rates after recovery. The results suggested a delay in absorption of $NaCl$ from the small intestine in idiopathic steatorrhoea and tropical sprue.

HADLEY, G. G. and CHINNOCK, R. F. **A study of hemograms in premature infants.** *J. Pediat.*, 1954, **45**, 413–418. [Dept. Pathol., Coll. Med. Evangelists, Los Angeles, Calif.]

In all, 643 samples of blood were obtained from 117 premature infants during the first year of life. Measurements of Hb, red cell count and packed cell volume and estimates of mean corpuscular Hb, mean corpuscular volume and mean corpuscular

Hb concentration are plotted against age in weeks. Average white cell count and percentage of lymphocytes are tabulated for different weeks of life. Most of the blood counts were made in the first 15 to 20 weeks.

The data show that the early anaemia of prematurity is normochromic, not hypochromic.

mezzo del polivinilpirrolidone. [The blood volume of the normal infant estimated by means of polyvinylpyrrolidone.] *Arch. ital. Pediat. Puertcoll.*, 1954, 16, 429-444. [Int. Clin. Paediat., Univ. Rome.] French, English and German summaries.

The literature on estimation of the blood volume in infants is reviewed.

The subjects of this study were 20 infants aged from 12 days to 12 months and 42 children of from 13 months to 12 years. They received by intravenous injection a 25 per cent. solution of polyvinylpyrrolidone, 1 ml. per 5 kg. bodyweight, and 2 ml. blood was taken 4 min. later for estimation of haematocrit and of the marker in the plasma.

The blood volume rose steadily with age in the infants from 251 ml. in the youngest to 717.4 in a boy of 12 months. The volume per kg. bodyweight ranged from 68.4 to 84.4 ml., without relation to age, with a mean of 77.7 ml. per kg., 75.8 in boys and 79 in girls. Plasma volume rose like blood volume, from 173 ml. in the youngest infant to 480.7 in the oldest. The volume per kg. ranged from 47 to 58, mean 52.6 ml., 53.9 ml. in boys and 51.5 in girls.

The steady increase in blood volume continued in the older children, reaching 2955 ml. in a boy of 12 years. The value per kg. bodyweight ranged from 72.6 to 93.1 ml., mean 79.4, and was the same in both sexes. The highest plasma volume was 1980 ml.; the values per kg. bodyweight were from 49.3 to 62.4, mean 54 ml.

ŠEVKOVIĆ, N. and MILOSAVLJEVIĆ, S. Uticaj rada na krvnu sliku konja. [Influence of work on the blood picture of the horse.] *Acta vet., Belgrade*, 1954, 4, No. 3, 53-58. [Inst. Ishranu, Vet. Fak., Belgrade.] German summary.

The blood picture was studied in 15 geldings and 4 mares of the Pešter hill breed. Seven were packhorses carrying loads and the others carted hay for a 10-hr. day. It was summer and the maximum temperature was 29.8° C. The horses were fed on good hay and pasture and were from 4 to 15 years old and in good condition.

The mean values before and after work were: Hb (Sahli) 57 and 62.5 per cent., red cell count 4.8 and 5.3 millions and white cell count 8.75 and 9.78 thousand. The proportions of white cells were not significantly altered. The differences due to the 2 types of work were not significant.

KRAMÁR, J., WILHELMJ, C. M., MEYERS, V. W., MILANI, D. P., GUNDERSON, D. E., SHUPUT, D., RACHER, E. M. and MAHONEY, P. S. (with GREEN, D. P. and NELSON, C.) Stress of fasting and realimentation as reflected in the capillary resistance and eosinophile count. *Amer. J. Physiol.*, 1954, 178, 486-492. [Dept. Paediat., Sch. Med., Creighton Univ., Omaha, Nebr.]

Capillary resistance and eosinophil counts were studied in 20 dogs which were starved, with water

only, for 39 to 67 days and then re-fed on different diets. During control periods on kennel diet the mean capillary resistance was 24 cm. Hg, means for individual animals 17 to 49. The mean eosinophil count was 156 per c.mm., range 47 to 416. There was no relation between the values. During fasting, capillary resistance increased and circulating eosinophils fell, the latter by 70 per cent. Re-feeding on high carbohydrate diets was not accompanied by restoration of these values to normal; high-protein diets rapidly reduced capillary resistance to normal, and eosinophils often rose above their control levels in an initial increase.

In 36 rats starved for 4 to 9 days capillary resistance rose and eosinophil counts fell. During re-feeding, whatever the diet, capillary resistance usually fell sharply to below normal for 7 to 20 days before returning to normal, and eosinophil counts changed inversely.

The specific and individual variations in response are discussed.—D. Duncan.

DUSTIN, J. P., SCHAPIRA, G., DREYFUS, J. C. and HESTERMANS-MEDARD, O. La composition en acides aminés de l'hémoglobine foetale humaine. [Amino-acid content of human foetal haemoglobin.] *C.R. Soc. Biol.*, 1954, **148**, 1207—1210. [Lab. Biochim. Méd., Brussels.]

The amino-acids of adult and foetal haemoglobins were separated by chromatography on Dowex 50. The concentrations of nearly all the amino-acids showed slight differences between the 2 forms, but the most striking was isoleucine. This was confirmed when it was separated from leucine by paper chromatography. The isoleucine content of foetal Hb was 1.04 and 1.11 per cent. in 2 samples, that of adult Hb 0.12 per cent.

HAWKINS, W. W., SPECK, E. and LEONARD, V. G. Variation of the hemoglobin level with age and sex. *Blood, J. Hematol.*, 1954, **9**, 999-1007. [Maritime Reg. Lab., Nat. Res. Council, Canada, Halifax, N.S.] Interlingua summary.

The Hb values of 1308 male subjects aged 6 to 98 years and of 1424 female subjects aged 6 to 94 years were surveyed in Halifax, Nova Scotia, during the winter and spring of 1952-53. Among boys and girls aged 6 to 14 years the values increased

from about 13 to about 14 g. per 100 ml. of blood; there was no significant difference between the sexes and the average was 13.5 g. Among girls aged 14 to 20 years the Hb values decreased slightly, reaching 13 g. per 100 ml.; among boys of the same age the values increased to about 15 g.; in both sexes the values attained at 20 years of age remained throughout the third decade of life and were, respectively, the lowest and the highest shown by female and male subjects of any age. In men between 20 and 60 years of age the Hb values were 14.5 to 15 g. per 100 ml.; after 50 years of age they fell progressively to reach on the average 12.4 in men aged 80 to 90 years. In women aged 20 years and upwards the average Hb values remained near 13 g. per 100 ml.

WADSWORTH, G. R. Haemoglobin levels of normal men and women living in a tropical climate. *Brit. Med. J.*, 1954, **ii**, 910-911. [Dept. Physiol., Univ. Malaya, Singapore.]

Hb values of 337 healthy men and 116 healthy women in Singapore, where the temperature ranges from 23° to 32° C. (73.4° to 89.6° F.) during the year, were measured. In both sexes there were Europeans who had been in Singapore for at least 6 months and Chinese and other Asiatics who had lived all their lives in the tropics. The method of Hb estimation is described in detail.

Hb in men ranged from 15.87 to 16.60, average 16.12 g. per 100 ml. blood, and in women from 13.80 to 14.07, average 13.88, with no significant difference between the races.

It is concluded that during a long sojourn in a hot climate Hb values adjust themselves to normal after a temporary fall. Lower Hb values found in natives of tropical areas by other workers were probably due to other environmental influences such as nutrition.—T. D. Bell.

KALDOR, I. Studies on intermediary iron metabolism. 4. Haemoglobin value, serum iron and iron binding capacity in normal and

castrated rats. *Austral. J. Exp. Biol. Med. Sci.*, 1954, 32, 437-440. [N.S.W. Red Cross Soc. Blood Transfusion Serv.]

(See also Absts. 3914, 4735, Vol. 23.)

Experiments were made on about 200 rats, half of them castrated at 6 to 10 weeks of age. Animals were killed for the tests in 3 batches 2, 5 and 7 months after castration. The Hb values showed no consistent sex difference, and no consistent change with age or castration. The serum Fe values in all 3 batches were about 50 per cent. higher for normal females than normal males, the values declining with age in both these groups. Castration reduced the serum Fe values in females, but caused little change in males. In neither sex after castration was there a significant decline with age. In spite of the low serum Fe values in males the total Fe-binding capacity values of both normal and castrated male groups were slightly higher than those of the corresponding female groups. No significant variation of total Fe-binding capacity was observed in either male or female rats.—M. B. Richards.

HOLEMANS, K. and MARTIN, H. Étude des protéines sériques chez les indigènes du Kwango. [Study of the serum proteins in natives of the Kwango.] *Ann. Soc. belg. Méd. trop.*, 1953, 33, 675-679. [Lab. Hôp. Feshi, Belgian Congo.] Flemish summary.

Total proteins, albumin and globulin were estimated by a micro-Kjeldahl method in the blood of 10 infants up to 1 year old, 25 children from 1 to 5 years, 24 from 5 to 15 years, 62 adults from villages and 25 adults who were soldiers or hospital orderlies.

The mean value for total serum proteins increased from birth to maturity, when it was higher than the normal for white races. Unlike those in the white races, after 17 years of age the mean albumin value declined with advancing age and the mean globulin value rose. The values for soldiers and hospital orderlies showed the same effect but not quite so clearly. The albumin:globulin ratio was so low that it would be regarded as pathological for white races.

The low serum albumin value is taken as evidence of protein undernutrition.—E. M. Hume.

WEHMEYER, P. Concentration of plasma proteins in the ox. 2. Variation in composition of the blood in the individual animals. *Nord. Vet.-Med.*, 1954, 6, 818-824. [Statens Seruminst., Copenhagen.] German and Danish summaries.

For part 1 see Abst. 623, Vol. 25.

Vol. 25, No. 2

Blood samples from 8 healthy cows showed individual differences in serum protein composition in the course of a day, a month and a year. The variation in globulin concentration was the greater and was independent of variation in the albumin concentration. Serum protein concentration varied independently of cell volume. An increase in cell volume usually coincided with a fall in sedimentation rate and *vice versa*, so the variation in concentration of serum proteins was considered unlikely to be associated with hydration or dehydration.

A method is described for estimating plasma volume in small animals.

In 2 series of 7 and 6 normal rats the plasma volume was from 3.5 to 4.5, mean 3.9 per cent. of bodyweight. In the second group, which were on controlled diet, the plasma volume was related to the weight of the brain, giving a mean value of 870 per cent. of brain weight \pm 5.7. In rats kept on a diet with 7 per cent. protein for 200 days and showing extensive liver lesions the plasma volume relative to brain weight was 15 to 44 per cent. below normal, but no relation was found between the fall in plasma volume and the extent of liver damage.

The total plasma protein in normal rats was estimated at 61.6 per cent. of the brain weight, with deviations from - 8 to + 5 per cent. Electrophoresis gave, per cent., albumin 37.5 and α -, β - and γ -globulins 22.1, 15.4 and 25, respectively. In protein-depleted rats the total protein was not diminished in those with the lowest plasma volumes but in 5 out of 8 the total protein was 22.8 to 43.7 per cent. below normal. Albumin or α -globulin or both were low, β -globulin was normal and γ -globulin increased to 42 per cent. The net result was a lower ratio of albumin plus α -globulin to β - plus γ -globulin. For absolute values there was a more important fall in total protein, albumin and α -globulin.—D. Duncan.

- GLAZIER, F. W., TAMPLIN, A. R., STRISOWER, B., DELALLA, O. F., GOFMAN, J. W., DAWBER, T. R. and PHILLIPS, E. Human serum lipoprotein concentrations. *J. Gerontol.*, 1954, **9**, 395-403. [Donner Lab., Div. Med. Phys., Dept. Phys., Univ. California, Berkeley.]
 Serum lipoproteins from 3573 subjects were separated by the ultracentrifuge into classes S_f 0-12, 12-20, 20-100 and 100-400. The slowing effect of concentration was taken into account. All 4 classes of serum lipoprotein continued to rise into the seventh decade of life in women; in men they reached a peak in the fifth or sixth decade and then decreased. From the third decade the mean levels of S_f 0-12 and S_f 12-20 in men were significantly higher than in women up to the sixth and fifth decades, respectively, when they became equal. In the seventh decade both mean levels were higher in women. For S_f 20-100 and S_f 100-400 the difference between the sexes after the first decade was maintained up to the sixth decade. The S_f 0-12 lipoprotein levels were significantly higher in the fasting than in the non-fasting state; the opposite was true for S_f 100-400 lipoproteins.

- RUBIN, L. and ALADJEM, F. Serum lipoprotein changes during fasting in man. *Amer. J. Physiol.*, 1954, **178**, 263-266. [Donner Lab., Div. Med. Phys., Univ. California, Berkeley.]

Blood samples were taken daily from 6 volunteers fasting for 4 or 5 days and the serum lipoproteins were separated by ultracentrifuge into 2 main fractions of low and high density. A significant rise in the low-density serum lipoprotein was found in 5 subjects. The other had been on a low-lipid diet for 2 years before the experiment. A change to normal diet restored the level of serum lipoprotein within 24 hr. High-density serum lipoproteins were not significantly affected during fasting.—A. Hepburn.

2127

- ALADJEM, F. and RUBIN, L. Serum lipoprotein changes during fasting in rabbits. *Amer. J. Physiol.*, 1954, **178**, 267-268. [Donner Lab., Div. Med. Phys., Univ. California, Berkeley.]
 Samples of serum lipoprotein from 16 rabbits were divided into 4 low-density fractions of S_f 0-12, 12-20, 20-100 and 100-400. High-density lipoproteins were negligible. The concentration of each lipoprotein fraction increased significantly after fasting for 3 days. At 7 days, S_f 12-20 and 20-100 lipoproteins were unchanged, S_f 0-12 had further increased and S_f 100-400 had returned to the pre-fasting level.—A. Hepburn.

- BROWN, H. B. and PAGE, I. H. The effect of oral iodide on serum butanol-insoluble protein
 N.A. and R., April 1955

bound iodine in various species. *Circulation*, 1954, 10, 714-720. [Res. Div., Cleveland Clin. Found, Ohio.] Spanish summary.

When iodides were administered to rabbits, dogs, rats and 9 hypertensive human patients, a substance called butanol-insoluble protein-bound iodine developed in the serum. It appeared a few days after iodide treatment was started and disappeared 4 to 8 weeks after treatment stopped. In all animals receiving no extra iodide, serum protein-bound I was completely soluble in butanol in acid solution, and consisted largely of alkali-insoluble I resembling thyroxine. The concentration of this fraction in serum was not increased by iodide. Most of the increase in protein-bound I in animals given iodide was butanol-insoluble. The daily dose of iodide by mouth required to produce measurable concentrations of butanol-insoluble protein-bound I in serum was 0.4 mg. I per kg. bodyweight for rabbits, less than 3 mg. for dogs, 8 mg. for rats and 7 to 13 mg. for man. Hypothyroidism reduced the iodide requirement to one-tenth of that needed to produce comparable amounts of butanol-insoluble protein-bound I in euthyroid animals. Hypothyroid rabbits given as little as 0.1 mg. iodide per kg. bodyweight had detectable amounts of serum butanol-insoluble protein-bound I. Similarly in dogs, but 4 times as much was required by hypothyroid rats. The maximum concentrations attainable appeared in rabbits at an iodide dose of 16 mg. per kg. bodyweight daily, at more than 20 mg. in rats, at from 35 to 40 mg. in man and at 63 to 94 mg. in dogs. One human patient had 21.5 μ g. per 100 ml. serum after 3 weeks on 14 to 24 mg. iodide per kg. bodyweight. The attainable concentration varied considerably with individuals.

The function of butanol-insoluble protein-bound I is unknown as yet. Its concentration in blood is related to the amount of ingested iodide and is one measure of the organism's response to I. Such a measure is important because of an apparent association of this substance with serum cholesterol changes in rabbits fed on cholesterol, in which large amounts of iodide retard and small amounts enhance the development of high blood cholesterol.

SERPA SANABRIA, L. M. and DE VENANZI, F. Fósforo inorgánico del suero en pacientes cancerosos. [Inorganic phosphorus of serum in patients with cancer.] *Acta científ. venezol.*, 1953, 4, 213-215. [Centro Invest. Cáncer, Caracas.]

Although the occurrence of high serum P was demonstrated in cancerous animals some years ago, little importance seems to have been attached to the occurrence of high serum P in patients with cancer. In 77 normal subjects the mean value for

inorganic P was 3.65 mg. per 100 ml. serum, in 42 patients with diseases of non-neoplastic nature 3.76, and in 82 with cancer 4.32, a difference of high statistical significance. In 76.8 per cent. of the cancer patients the concentrations were above 4.0 mg. per 100 ml. serum, compared with 22.1 and 31.1 per cent. in the first 2 groups; 30 per cent. of the patients with neoplasms had concentrations between 4.5 and 5.0 mg.

It is suggested that serum inorganic P should be estimated in patients suspected of malignant neoplasms.—M. B. Richards.

EVANS, J. V. Electrolyte concentrations in red blood cells of British breeds of sheep. *Nature*, 1954, 174, 931-932. [Rowett Res. Inst., Bucksburn, Aberdeenshire.]

Of 93 Scottish Blackface sheep examined with the same plasma level of K and Na, 47 had a mean concentration in the red blood cells of 36 m. equiv. and 46 a mean of 13 m. equiv. K per litre. The 1:1 ratio of the high- and low-K types (HK

and LK) was not found in 43 Cheviot sheep, 7 being HK and 36 LK. Widdas (Title 636, Vol. 25) found 8 HK and 14 LK in 22 pregnant Welsh ewes. In the 3 breeds mentioned there seem to be 2 types with varying distribution. Merino sheep (Denton *et al.*, *Acta med. scand.*, 1951, 140, Suppl. 261) appear to be mostly LK, and LK, HK and intermediate types have been found in Lebanese fat-tailed sheep (Abst. 487, Vol. 7).—A. Hepburn.

SIMMONDS, W. J. **The effect of fluid, electrolyte and food intake on thoracic duct lymph flow in unanaesthetized rats.** *Austral. J. Exp. Biol. Med. Sci.*, 1954, 32, 285-299. [Kanematsu Mem. Inst. Pathol., Sydney Hosp.]

Cannulae were inserted into the thoracic lymph ducts of adult rats, which also had gastrotomy tubes in the cardiac region of the stomach. Lymph collection was possible for from 1 to 4 days after operation.

When 0.9 per cent. NaCl solution was dripped into the stomach at about 20 ml. per kg. per hr. for 8 hr., more lymph and less urine were produced than when distilled water replaced the saline; the water diuresis decreased the lymph flow. With both fluids protein output rose as the lymph flow increased.

A single dose of 16 to 20 ml. water per kg. body-weight produced much the same increase in lymph flow as did saline, but the peak was reached and passed earlier and the lymph protein was more diluted after water.

A hypotonic solution of 0.5 g. serum albumin in water resembled water in its effect on lymph flow, but hypertonic glucose solution resembled saline. Large doses of olive oil or oleic acid produced a prolonged increase in lymph flow independently of the volume of fluid given, but smaller doses of fat as full-cream milk had little effect.—D. Duncan.

2140

KORNER, P. I., MORRIS, B. and COURTICE, F. C. **An analysis of factors affecting lymph flow and protein composition during gastric absorption of food and fluids, and during intravenous infusion.** *Austral. J. Exp. Biol. Med. Sci.*, 1954, 32, 301-320. [Kanematsu Mem. Inst. Pathol., Sydney Hosp.]

Experiments were made on 58 cats anaesthetised with Nembutal; catheters were inserted into the thoracic lymph duct, femoral artery and lower inferior vena cava.

Intravenous infusion of Ringer Locke solution increased venous pressure and lymph flow. Plasma protein concentration fell relatively less than lymph protein concentration, but the two were related and the latter was independent of the rate of lymph flow. The albumin:globulin ratio in lymph did not change. Experiments with T 1824 showed that large infusions of Ringer Locke solution greatly increased the rate of protein exchange between plasma and lymph. The percentage loss of protein labelled with T 1824 from the plasma in 5 hr. was about twice that of total protein; this is ascribed to mobilisation of new unlabelled protein into the circulation. About 25 to 30 per cent. of the dye lost from the plasma was recovered in the lymph.

In 43 cats operated on 3 to 4 hr. after being fed the spontaneous lymph flow was about 33 per cent. greater than in 23 cats starved, but allowed water, for 24 hr. The protein content of the lymph was directly related to plasma protein concentration and inversely to rate of lymph flow in starved cats, but was independent of flow in fed cats.

In 4 cats given Ringer Locke solution by stomach tube at 40 ml. per kg. per hr. the lymph flow increased from the third hour and continued to rise for 2 hr. after the infusion ceased. When water was thus given to 3 cats the lymph flow reached a peak in the second and third hours, falling abruptly when infusion ceased. During water absorption lymph protein varied inversely with flow, but during saline absorption lymph protein varied directly with plasma protein as well as inversely with flow.

All protein fractions in plasma were present also in lymph. When water was given by mouth there was intravascular haemolysis and free Hb appeared in the lymph 1 to 2 hr. later.—D. Duncan.

2141

ROTHSCHILD (Lord) and BARNES, H. **Constituents of bull seminal plasma.** *J. Exp. Biol.*, 1954, 31, 561-572. [Dept. Zool., Univ. Cambridge.]
Seminal plasma was prepared from semen samples collected from 10 bulls of different breeds and ages.

The mean value of Δ from 40 samples was -0.528 and the range from -0.50 to -0.58 , with one value of -0.71 . Some of the semen diluents in common use have too high and others too low an osmotic pressure. The average concentrations and ranges of several constituents, in mg. per 100 ml., were: Na 258.2, 152 to 370; K 171.6, 50 to 387; Ca 37.3, 24 to 60; Mg 8.4, 0.1 to 18; Fe 2.1, 1 to 4; chloride 174.8, 100 to 293;

N.A. and R., April 1955

citric acid 620.2, 357 to 818; fructose 459.7, 26 to 872; total N 876.9, 441 to 1169; and total P 56.9, 16 to 91. Correlations between these constituents are tabulated. Na and K were negatively correlated, $r = -0.86$ and $P < 0.001$. Ca, chloride, fructose, citrate and total N were also closely correlated.

Results for Na and K obtained with the flame photometer were less reliable than those of chemical analysis.—D. Duncan.

GLEGG, R. E., EIDINGER, D. and LEBLOND, C. P. Presence of carbohydrates distinct from acid mucopolysaccharides in connective tissue. *Science*, 1954, 120, 839-840. [Dept. Anat., McGill Univ., Montreal.]

Connective tissue from cattle lung, Achilles tendon, skin, ligamentum nuchae, tracheal cartilage and bone matrix was extracted with NaOH. The neutralised extracts were fractionally precipitated with alcohol to yield fractions 1, containing acid mucopolysaccharide, and 2. Both fractions and washed lens capsule were analysed by paper chromatography for monosaccharides after hydrolysis for 2 days at 100° C.

Fraction 1 contained glucuronic acid, unlike fraction 2, which contained galactose, mannose and fucose and, in some preparations, glucose. The high N content of 10 to 15 per cent. in fraction 2 suggested the association of protein with the extracts.

The periodic acid Schiff technique for detection of carbohydrates, containing free 1:2-glycol (and α -amino-alcohol) groups stained lens capsule sections intensely, cartilage and bone matrix moderately, collagenous fibres in the derma weakly, and tendon fibres not at all. Application of a commercial sample of "pectinase" to sections of derma and tendon produced an intense stain in the collagenous fibres. The elastic fibres of ligamentum nuchae did not stain even when previously treated with pectinase, which changed the stain of the interstitial material from weak to intense. Since fraction 2 reacted intensely in the periodic acid Schiff spot test and fraction 1 did not, the staining of fraction 2 was attributed to the carbohydrate moiety.—A. Hepburn.

CIZEK, L. J. Total water content of laboratory animals with special reference to volume of fluid within the lumen of the gastrointestinal tract. *Amer. J. Physiol.*, 1954, 179, 104-110. [Dept. Physiol., Coll. Phys. Surg., Columbia Univ., New York.]

Observations were made on rabbits, guinea-pigs, rats and dogs, a few on mice and hamsters and one goat. With manipulations made as rapidly as possible the animals were killed, their intestines were emptied and carcass weight was measured as liveweight minus that of intestinal contents. In all specimens, contents and carcasses, moisture was estimated by drying to constant weight at 100° C. For the first 3 species data are tabulated which refer to normal feeding, deprivation of food for up to 28, 5 or 7 days and of both food and water for 7, 5 or 5 days, respectively.

During normal feeding water in the lumen of rabbit's intestine is about 15 per cent. of total body water; the lowest percentage, 7.6, was in females after 7 days without food or water. For guinea-pigs a sex difference was found in those feeding normally, 20 per cent. in males, 16.9 per cent. in females; in those without food or water it was 10.3 and 11.3 per cent. after 5 days. In rats normally fed it was 6.7 per cent. in both sexes and 1.5 and 2.4 per cent. in males and females after 5 days without food or water. For dogs 2 hr. after eating the percentages were 9.7 and 6.4 and, after 48 hr. without food but with water, 1.4 and 1.3 per cent., for males and females.

For mice and hamsters feeding normally corresponding values were 8.7 and 11.3 for males and 11.5 and 12.5 per cent. for females. In the one male goat 16.3 per cent. of the total body water was in the lumen of the intestine.

The pitfalls that these data may provide in the estimation of extracellular fluid by the use of substances such as inulin and sucrose, which do not enter the gut, are discussed.—D. Harvey.

GROLLMAN, A. (with CAMPBELL, C., MIMS, J. and RECTOR, F.) The water and electrolyte content of the tissues in hypertension. *Circulation Res.*, 1954, 2, 541-543. [Dept. Exp. Med., Southwestern Med. Sch. Univ. Texas, Dallas.]

Adult rats with high blood pressure produced by a choline-deficient diet given for 10 days after weaning had no apparent loss of parenchymal

renal tissue and less damage in the parenchyma than in hypertension produced by other methods. Water, Na, K, Mg and chloride estimated in brain, gut, heart, liver, skeletal muscle and skin were similar to those of the controls. A second group of hypertensive rats treated with a renal extract to reduce blood pressure gave similar results. The changes in water and electrolyte content in the tissues found by previous workers (Abst. 2063, Vol. 20) were considered to be due to renal disturbances and not to high blood pressure.

HARKNESS, M. L. R. and HARKNESS, R. D. The relation of collagen content of the liver to body weight in the rat. *J. Physiol.*, 1954, **125**, 447-452. [Dept. Physiol., University Coll., Gower Street, London, W.C.1.]

Rats, 42 male and 7 female, under 1 year old and weighing 25 to 400 g., which had been allowed a stock diet to appetite until death, were killed and the collagen content of the right lobes of the liver was estimated. The relation of liver weight to bodyweight was the same in males and females; linear relations were found between both weight and collagen content of the liver and bodyweight and could be expressed as

$$w(g.) = 0.0203 W(g.)^{0.91}$$

$$c(mg.) = 0.0124 W(g.)^{1.09}$$

where w and c are weight and collagen content of the liver and W is bodyweight. Thus, liver weight increases less rapidly and liver collagen more rapidly than bodyweight.—G. F. Garton.

WALKER, A. R. P. and ARVIDSSON, U. B. Studies on human bone from South African Bantu subjects. 1. Chemical composition of ribs from subjects habituated to a diet low in calcium.

HIGGINSON, J. 2. Histopathological changes in the ribs of South African Bantu infants. *Metabolism*, 1954, **3**, 386-391; 392-399. [Human Biochem. Unit, S. African Inst. Med. Res., Johannesburg.]

1. Ash, Ca and P were estimated in dry, defatted and occasionally demarrowed fifth ribs from 44 Bantu infants, 13 children and 12 adults; ribs from 18 European infants and 22 adults were

analysed for comparison. No significant difference was found between the percentage composition of either infant or adult ribs from the two races. All the data were in close agreement with those reported for white subjects both in South Africa and in western countries. It is concluded that although the Bantu diet is low in Ca and vitamin D and high in phytate P and has an adverse Ca:P ratio this does not prevent the formation of bone with a normal mineral composition under local conditions, including plentiful sunlight. In some infants, mainly breast fed, who were dying of rickets, the low mineral content of the bone was believed to be due to vitamin D deficiency and insufficient exposure to the sunlight available.

2. The costochondral junction of the fifth rib of 80 Bantu infants who died from kwashiorkor, gastro-enteritis, tuberculosis or respiratory or other disease was examined histologically. Thirteen ribs from European infants and ribs from a few Bantu adolescents and adults were also studied. Details and diagrams are given of the findings. Growth depression was the most frequent lesion observed, and it was most marked in subjects with kwashiorkor. Histological evidence of rickets was found in 20 infants. It is suggested that osteoporosis among these infants is probably due to growth depression rather than to rickets.

CURZON, G. Longitudinal distribution of organic components of bone. *Nature*, 1954, **174**, 646-647. [Inst. Orthopaedics, Brockley Hill, Stanmore, Middlesex.]

In the femur of a goat aged 18 months the galactose, glycogen, hydroxyproline and tyrosine contents were lowest in the shaft and highest at the epiphyses. Galactose and glycogen, especially the former, were highest in the epiphyseal plate. Hydroxyproline, a measure of collagen content, was not higher in the epiphyseal plate than in the other end sections of the bone.—D. Duncan.

2151

GRIFFITH, G. C., BUTT, E. M. and WALKER, J. The inorganic element content of certain human tissues. *Ann. Int. Med.*, 1954, **41**, 501-509. [Dept. Cardiol., Sch. Med., Univ. S. California, Los Angeles.]

Estimations of Cu, Fe, Pb, Mn, Zn and Hg in liver, kidney, heart, brain, lung and spleen were made by chemical and spectrophotometric methods on material obtained at 910 post-mortem examinations. The data are tabulated, with standard deviations, for ages under 3 months, 3 months to 1 year and thereafter for decades of age to the ninth.

In particular Hg content is considered in relation to the effect on the kidney of therapeutic administration of its compounds. It is concluded from the data for 45 patients so treated for congestive heart failure that a trace of Hg may be found in tissues at all ages and that, in the absence of anuria due to low blood Na, small or even massive doses are not injurious to the kidney.—D. Harvey.

HART, P. C. **An investigation into the content of trace elements in cow livers.** *Netherlands J. Agric. Sci.*, 1954, **2**, 298-302. [Inst. Animal Husb. Res. T.N.O., Utrecht.]

Copper, zinc, manganese, molybdenum and cobalt were estimated in the livers of 62 cows. Half of the animals had been treated for 5 weeks with Vevoron, an antithyroid preparation containing methylthiouracil, for fattening. On a low-protein diet the Vevoron had increased slaughter weight and the weight of the livers.

The contents in $\mu\text{g. per g. dry liver}$ of Cu, Zn, Mn, Mo and Co in control animals were 116, 144, 10.9, 4.98 and 0.37. In experimental animals they were 120, 125, 8.4, 4.24 and 0.34. Zn, Mn and Mo were significantly decreased by Vevoron. Cu and Co were not significantly affected.

In animals with infections except fascioliosis of the liver, and those with fascioliosis of the liver only, the only difference in content of trace elements in the livers was in Cu, which was higher in the healthy animals.—T. D. Bell.

RYŚ, R. **Zawartość cystyny w wełnach owiec hodowanych na obszarze Polski. [Cystine content of the wool of sheep bred in Poland.]** *Rocz. Nauk. rol.* [B], 1954, **68**, 67-86. [Lab. Centralne, Pracownia Biochem.] Russian and English summaries.

The average cystine content of the wool was the same in the inner and outer layers of the fleece of Zackel sheep bred in Poland and in different areas of Merino fleeces. The cystine content was higher in breeds developed for good fleeces, and was directly proportional to the quality of the wool. It is suggested that the cystine content might be used as an additional method for grading wool.—T. D. Bell.

BURLEY, R. W. **Sulphydryl groups in wool.** *Nature*, 1954, **174**, 1019-1020. [Nat. Chem. Res. Lab., S. African Council. Sci. Indust. Res., Pretoria.]

This is a modification of the method of Scott and Fleisch (*Science*, 1954, **119**, 70) for estimation of sulphydryl groups with 1-(4-chloromercurenylphenylazo)-naphthol-2. A sample of 50 mg. wool of known moisture content is shaken with a formamide solution of the reagent containing 4 mg. per 100 ml. The wool fibres swell in the formamide, allowing the reagent to penetrate. The concentration of sulphydryl groups was estimated after 4 days when the rate of reaction had reached a small but finite value, by measuring the decrease in colour intensity of the reagent.

Typical South African merino wool contained on the average 7 micromoles of sulphydryl groups per g. dry wool. Wool from sheep deficient in Cu contained more sulphydryl groups, and the relative mechanical weakness of this wool can be explained by a lower formation of cystine linkages.

NERENBERG, S. T. Beta granules of islets of Langerhans of rat: a study of their development under normal and abnormal conditions. *Arch. Pathol.*, 1954, **58**, 236-240. [Dept. Pathol., Univ. Minnesota, Minneapolis.]

Sections of pancreas were studied from foetal rats from the seventh to the twenty-first day of gestation and from young rats from birth to 3 weeks old. The pancreases were stained with a modified Gomori chrome alum haematoxylin method for demonstrating alpha and beta granules in the islets of Langerhans.

Beta granules were first seen on the twentieth day of gestation, and beta cells were well filled with granules in the newborn rats, but no alpha granules appeared until the fourth day of life. Administration of insulin to the mothers throughout pregnancy did not affect the development of beta granules in the foetus, nor did starvation in the newborn. In young from alloxan-diabetic mothers there was no beta granulation until 24 hr. after birth, but in one killed at birth alpha cells were strikingly prominent. The results with cortisone were not conclusive, but there appeared to be no significant effect on the beta granules.

ORTIZ DE LANDÁZURI, E., ESCOBAR DEL REY, F., MORA LARA, R. J., SÁNCHEZ AGESTA, A., RODRÍGUEZ MORENO, F. and MORATA GARCÍA, F. Exploración de los procesos hipoparatiroides. [Hypoparathyroid conditions.] *Rev. clín. española*, 1954, **55**, 5-19. [Clín. Med., Univ. Granada.] English, German and French summaries.

After a classification of types of hypoparathyroidism, the functional tests, both classic and modern, applied in studying the condition are discussed. A detailed study, based on these tests, is reported for 2 patients, one with genuine hypoparathyroidism, in whom the Ellsworth Howard test with parathyroid hormone was positive, and the other with pseudohypoparathyroidism which gave a negative result with this test. It is

concluded that the parathyroid hormone diminishes tubular reabsorption in genuine, but not in false hypoparathyroidism. In the former the hormone causes a rise in blood Ca and a fall in blood P; without hormone the phosphate level rises first, and later the Ca level falls. This points to a primary effect on P metabolism and a secondary effect on that of Ca. Vitamin D₂ acts above all on blood Ca, probably as a result of improved Ca uptake from the intestinal lumen. Administration of a protein diet with vitamin D₂ and CaCl₂ improves the humoral and clinical picture in hypoparathyroidism. The Ellsworth Howard test is considered effective, provided certain precautions outlined in the paper are observed.—M. B. Richards.

BRENNER, O., BLACK, A. B. and GADDIE, R. Estimation of the rate of thyroid hormone secretion in man. *Clin. Sci.*, 1954, **13**, 441-451. [United Birmingham Hosps.]

Of 12 patients selected, 6 had thyrotoxicosis, 2 had myxoedema, 3 had normal thyroids and 1 had a high B.M.R. but no clinical evidence of thyrotoxicosis. Daily collections of faeces and 24-hr. specimens of urine were made during the 2 weeks of the experiment. Each patient was given 5 to 10 mC. of ¹³¹I as Na¹³¹I by mouth. One hr. later and then every 24 hr., 30 ml. blood was taken and 4 or 5 ml. serum was used for estimation of protein-bound iodine radio-activity. The radio-activity of faeces and urine was also studied. Details are given of the method of calculating the daily secretion of thyroxine from the data obtained; the validity of the method is discussed, and possible sources of error. In the 3 euthyroid patients the daily secretion of thyroxine estimated by this method was 163 to 274 µg. In the 2 myxoedematous patients it was 10.5 and 17.8 µg. In the 6 thyrotoxic patients it was 247 to 2603 µg. and in the single patient with the high B.M.R., 1396 µg.—B. W. Simpson.

EDWARDS, D. A. W., ROWLANDS, E. N. and TROTTER, W. R. **The mechanism of the goitrogenic action of *p*-aminosalicylic acid.** *Lancet*, 1954, 267, 1051-1052. [Dept. Clin. Res., University Coll. Hosp. Med. Sch., London.]

Previous investigators have noted that among patients receiving treatment with *p*-aminosalicylic acid (PAS) a few developed mild goitre with myxoedema. The mechanism of the effect was studied.

PAS did not reduce the concentration of iodides by thyroid or by saliva, but inhibited formation of thyroid hormone. In 4 patients who had previously received large therapeutic doses of ^{131}I and whose blood levels of ^{131}I remained steady, the concentration of ^{131}I in the saliva was not altered by administration of PAS, nor was the concentration of iodides in the thyroid. Two patients with toxic goitre were given 5 g. sodium PAS by mouth and, 1 hr. later, an oral dose of ^{131}I . The radio-active count over the thyroid rose and levelled off in about 1 hr., and 200 mg. KClO_3 was then given to discharge any iodides not organically bound. The proportion of ^{131}I discharged, expressed as a percentage, was a measure of the effectiveness of PAS in blocking hormone formation. In one patient 30 per cent. only was discharged, indicating a slight block, but in the other 95 per cent. was discharged, indicating almost complete block.

This mild form of goitre induced by PAS could be effectively treated with thyroid or thyroxine preparations, but not with iodides. As half of a single dose of PAS is excreted by the kidneys in 3 hr. the goitrogenic complication is slight and easily overcome.—B. W. Simpson.

ZIMMERMAN, L. M., SHUBIK, P., BASERGA, R., RITCHIE, A. C. and JACQUES, L. **Experimental production of thyroid tumors by alternating hyperplasia and involution.** *J. Clin. Endocrinol.*, 1954, 14, 1367-1373. [Dept. Surg., Chicago Med. Sch., Ill.]

Young adult rats were alternately given propylthiouracil to produce hyperplasia and KI to produce involution of the thyroid. The former was administered as 0.1 per cent. and the latter as 0.01 per cent. in the drinking water. Two control groups were kept continuously on propyl-

thiouracil and KI, respectively. After a year all the rats were killed.

Tumours in the thyroids of the experimental rats were more numerous than in the control group on propylthiouracil. The thyroids of rats which had undergone alternate hyperplasia and involution showed localised areas of hyperinvolution. Three types of neoplastic change were seen. The first consisted of cords of cells and of small elongated acini containing little or no colloid. The cells were tall and columnar. No capsule had formed. The second was a type of benign adenoma consisting of closely packed cells with abundant granular cytoplasm, but again no capsule. The third type was found once only, a large cyst almost entirely replacing the thyroid lobe and filled with papillary projections.

Although the production of nodular goitre was not achieved, such an alternation of activity and rest was more effective in the production of neoplasms than sustained stimulation.

B. W. Simpson.

2170

HIGHLEY, D. R., PARKER, H. E. and ANDREWS, F. N. **Quantitative interrelationships between the effects of iodine and thiouracil on thyroid function.** *J. Nutrition*, 1954, 54, 249-256. [Dept. Biochem., Purdue Agric. Exp. Stat., W. Lafayette, Ind.]

Weanling male rats were divided into 16 groups of 10 and fed on diets containing 20, 100, 400 and 1600 μg . iodine per kg. for 6 weeks. During the 5th and 6th weeks 3 diets at each I level were supplemented with thiouracil, 0.005, 0.025 and 0.10 per cent. The greatest effect of the thiouracil was exerted when the I level was near the minimum required to prevent thyroid enlargement in the normal rat. High dietary I decreased, but did not prevent, the goitrogenic effect on thyroid weight and I content. Growth rate was not affected by the I intake when the thiouracil level was 0.005 per cent. or less. The growth-reducing effect of 0.025 per cent. thiouracil was counteracted by 400 μg . I per kg., but the growth-reducing effect of 0.1 per cent. thiouracil was not neutralised by 1600 μg . per kg. The addition of thiouracil to the diet increased thyroid size at all levels of I intake, but more at 100 and 400 than at 20 or 1600 μg . I per kg. The thyroid weight was proportional at the lower I intakes to the log log of the dose of thiouracil, but at 400 and 1600 μg . per kg. it was proportional to the log of the dose of thiouracil. When thiouracil was continuously in the diet for 6 weeks adrenal enlargement occurred at the 2 lower levels of I intake.—B. W. Simpson.

KRÜSKEMPER, H. L. and KLEINSORG, H. **Zur anti-thyreoidalen Wirkung von Kaliumperchlorat.**

[Antithyroid action of potassium perchlorate.] *Arch. exp. Pathol. Pharmacol.*, 1954, **223**, 469-480. [Med. Klin., Univ. Göttingen.]

Experiments were made on intact rats and rats from which the pituitary was removed. $KClO_4$, 100 or 250 mg. per kg. bodyweight daily, had no effect on weight gain, muscle, blood or liver. Thyroid weight rose to more than twice normal in 28 days, and returned spontaneously to approximately normal when $KClO_4$ was stopped. Thyroxine counteracted this effect and it did not occur when the pituitary had been removed. $KClO_4$ had no direct effect *in vitro* on respiration of liver but the respiration of liver removed after treatment was reduced. The effects of thyroxine on tissue metabolism *in vitro* and on bodyweight were not counteracted by $KClO_4$. No toxic effect was seen and the adrenals showed no reaction.

The effect on metabolism and thyroid weight of 250 mg. per kg. daily for 14 days was similar to that of 100 mg. methylthiouracil.—I. Leitch.

MELLEN, W. J. and WALLER, E. F. Antibiotics and thyroid size in growing chickens. *Poultry Sci.*, 1954, **33**, 1036-1037. [Dept. Animal and Poultry Indust., Univ. Delaware, Newark.]

Duplicate groups of day-old chicks were given a normal ration with: (1) no supplement, (2) 75 g. aureomycin per ton, (3) 100 g. bacitracin per ton, and (4) 100 g. furazolidone per ton. All chicks were injected intraperitoneally at 3½ weeks of age with the agent of chronic respiratory disease and spray-vaccinated with Newcastle disease vaccine at 5 weeks and 5 weeks of age. At 8 weeks of age the thyroids in groups 2, 3 and 4 were considerably larger than in the controls, but the increase in liveweight due to the antibiotics accounted for some of this greater thyroid size.—M. J. Head.

DELOIRME, M. L. and CAROIT, M. Étude de la diurèse et recherche d'un principe anti-diurétique au cours des hépatites provoquées par le régime hypoprotéidique chez le rat. [Study of diuresis and research on an anti-diuretic principle during hepatitis induced by low-protein diet in the rat.] *Arch. Sci. physiol.*, 1954, **8**, 329-347. [Bichat Hôp., 170 Boulevard Ney, Paris.]

Rats of initial weight 100 g. fed for 6 months on a diet providing 7 per cent. protein excreted less urine than controls on normal diet. At the twenty-sixth week the mean daily output was 10 ml. in the former and 77 ml. in the latter. The Na output was between 6 and 24 m. equiv. per litre in protein-deficient and 130 m. equiv. per litre in normal rats. Neither the differences in the diet nor those in growth appeared to account for these findings, and no renal lesion was found.

When normal rats received by stomach tube a water load of 5 per cent. of their bodyweight the resulting diuresis was inhibited by intraperitoneal injection of urine from protein-deficient rats or from 6 patients with hepatitis, but not by urine from normal rats or men.

The urine from protein-deficient rats and that from 14 patients (and possibly from 2 more) out of 21 with hepatitis had an oxytocic effect on guinea-pig uterus *in vitro*, which was not found in urine of normal rats or men. In the human subjects the presence of this substance was correlated with a low output of urine.

The results support the hypothesis that the antidiuretic substance is the posterior pituitary hormone.—D. Duncan.

GIACALONE, O. Influenza di estratti acquosi di testicolo e di ovaio sui limiti di resistenza alla iposalimentazione e sulla perdita percentuale giornaliera del peso corporeo. [Influence of aqueous testicular and ovarian extracts on the limits of resistance to underfeeding and on the daily percentage loss of weight.] *Bol. Soc. ital. Biol. sper.*, 1954, **30**, 49-51. [Ist. Fisiol., Univ. Palermo.]

Three groups of 5 adult rats were fed on a diet of, per cent., wheat starch 75, casein 10, butter 10, salts 5, with vitamins and fresh liver extract. The intake was restricted to 0.215 to 0.222 Cal. per g. bodyweight daily. On alternate days, a subcutaneous injection was given to one group of whole extract of testis equivalent to 30 cg. of the organ, to another group of whole extract of ovary equivalent to 5 cg. of the organ, and to the third group of saline. The rats given saline and those given ovarian extract died in a mean time of 54.4 and 53.6 days, both groups having lost a mean amount of 0.89 g. daily. The corresponding values for the rats given testicular extract were 49.0 and 1.0.—E. M. Hume.

ENERGY EXCHANGE AND SPECIFIC DYNAMIC ACTION

2175

KULIN, L. Die Berechnung des Kalorienbedarfes beim atrophischen Säugling. (Unter besonderer Berücksichtigung der Erfahrungen im Klimamilieu.) [Calculating the calorie requirement of the atrophic infant. With special reference to findings in the constant-temperature room.] *Ann. paediat.*, 1954, **183**, 162-188. [Kinderklin., Univ. Debrecen.] English and French summaries.

Observations were made on 70 atrophic infants. Their energy requirements were higher than those of normal infants when calculated from age and body mass, but showed great variation. When these infants were nursed in a controlled environment their requirements became much more stable, and 91 per cent. of them required 120 to 150 Cal. per kg. daily. It is necessary to supply from 10 to 30 per cent. more than the intake calculated from age and body mass. The ideal environment was found to be 28° to 30° C. and R.H. 55 to 70 per cent., so that much energy was not required for maintenance of body temperature.—D. Duncan.

SUZUKI, S., NAGAMINE, S., KAWADA, S., KUGA, T., YAMAKAWA, K., OSHIMA, S., HATTORI, B. and MIURA, S. [Studies on feeding standard of the National Safety Force. 5. On basal metabolism of the National Safety Force personnel at Camp Obihiro, Hokkaido.] *Jap. Safety Forces Med. J.*, 1954, **1**, No. 6, 19-29. [Div. Physiol., Nat. Inst. Nutrit.] In Japanese: English summary.

For earlier papers see Abst. 713, Vol. 25.

Data on basal metabolism, body measurements and how the time of 182 infantry personnel was spent are presented in tables in Japanese.

Body measurements, especially weight and chest girth, were superior to those of the average Japanese.

Average basal metabolic energy was 44.2 Cal. per hr. per sq. m. body surface, as compared to 42.5 Cal. found in 20 infantry personnel of Camp Nerima, Tokyo. (From summary.)—T. D. Bell.

2177

HATTORI, B. *et al.* [Studies on feeding standard of the National Safety Force. 6. On basal metabolism of the infantry personnel at Camp Kanoya, Kyushu.] *Jap. Safety Forces Med. J.*, 1954, **1**, No. 7, 11-22. [Ground Self-Defence Force Med. Sch.] In Japanese: English summary.

The mean basal metabolic rate for 236 subjects was 43.4 Cal. per hr. per sq. m. body surface,

Vol. 25, No. 2

slightly lower than that for 182 subjects at Hokkaido, where the climate is colder. (From summary.)—D. Duncan.

2178

KENYON, F., KELLY, H. J. and MACY, I. G. Basal metabolism of girls in the Great Lakes region. Need for continuous promotion of iodized salt. *J. Amer. Dietetic Assoc.*, 1954, **30**, 987-990. [Michigan Dept. Health, Detroit.]

The subjects were 67 apparently healthy Michigan girls aged from 5 to 18 years who were reared in the Great Lakes region during a goitre control programme. The Benedict Roth closed circuit apparatus was used for a total of 710 measurements of B.M.R. Twenty-five to 30 per cent. of the girls had basal metabolic rates within the range of 0 to -5 per cent. This tendency towards low rates emphasises the need for continuous propaganda for the use of iodised salt in goitre areas.—F. C. Aitken.

ARDY, C. and PONTREMOLI, S. Su alcuni aspetti del ricambio respiratorio dopo carico endovenoso di grassi. [Respiratory exchange after fat is given intravenously.] *Quad. Nutrizione*, 1953, **13**, 152-165. [Ist. Fisiol., Univ. Genoa.] The evidence in the literature on the possible conversion of fat to carbohydrate in the body is considered to be incomplete.

Basal metabolism was studied with Haldane's open circuit apparatus in 7 dogs weighing between 3.1 and 6.2 kg., starved for 12 hr. and in thermal neutrality. Changes in weight, oxygen consumption, CO₂ and water output and R.Q. were estimated for 10 hr. The experiments were later repeated when the dogs had received, after fasting for 12 hr., an intravenous infusion of an emulsion of 9 g. coconut oil per kg. bodyweight; and on another occasion when they received in the same way 6.99 g. glucose per kg. bodyweight in 15 per cent. solution. The fat and glucose provided the same amount of carbon.

In the second 5 hr. of experiments in which the dogs received fat emulsion there was a considerable

reduction in the mean hourly loss of bodyweight : after glucose the weight loss was similar to that of fasted dogs. This decreased weight loss after fat was accompanied by a low R.Q. of 0.63 ± 0.13 , compared with the fasting R.Q. of 0.79 ± 0.06 and one of 1.03 ± 0.15 in the second 5 hr. after glucose. Output of water was similar in all experiments.

The results are considered to support the theory that fats can be converted to carbohydrate in the body.—D. Dumeau.

LIQUORI, G. Il dispendio energetico nel lavoro dei salinieri. Studio nelle saline di S. Gilla (Cagliari). [Energy expenditure by workers in salt mines. Study in the salt mine of S. Gilla, Cagliari.] *Quad. Nutrizione*, 1953, **13**, 120-142. [Ist. Fisiol., Univ. Cagliari.]

Energy expenditure was computed for the working day from analysis in a Haldane Margaria apparatus of expired air collected in a Simonson bag. Basal metabolism was taken from Boothby and Sandiford's modification of Du Bois's tables after deduction of 10 per cent. to fit Italian values. The work is described. For 11 *attolatori* (gatherers) the mean age was 42, weight 57 kg., height 160 cm. and surface area 1.59 sq. m.; standing at rest their R.Q. was 0.88, oxygen consumption per min. 207 c.c., equivalent to 1.03 Cal.; at work R.Q. was 0.93, and oxygen consumption 935 c.c., or 4.28 Cal. Similar data are given for 20 *carrucianti* (loaders) and a total of 20 *caricatori* (barrowmen) in 2 groups on different tasks. With comparable allowances for rest in the canteen, cycling 20 km. (B.M. + 240 Cal. per hr.), domestic activities (B.M. + 65 per cent.) and sleep (B.M. + 10 per cent.), the daily expenditures of the groups are computed to be [without decimal points] 3272, 3889, 3210 and 3546 Cal. The work of loading, at the rate of 7.09 Cal. per kg. bodyweight per hr., is "very heavy", demanding frequent rest pauses.

HETTINGER, T. and WIRTHS, W. Arbeitsphysiologische Untersuchungen über Korbform und Trageart beim Kartoffellegen. [Physiology of work : shape of basket and mode of carrying it in potato planting.] *Arbeitsphysiologie*, 1954, **15**, 364-372. [Max Planck Inst. Arbeitsphysiol., Dortmund.]

Baskets of oval or kidney shape, carried by handles or suspended in front of the body by a strap over the back, were used in respiration tests in the field, on the energy expended in planting potatoes and filling the baskets from a sack. In all tests the energy expenditure for planting was on the average 4.3 Cal. per min., and for filling a basket 3 to 4 Cal. The planting of a hectare required about 7400 work Cal. The subjective

feeling of strain and the increase of pulse frequency in the work of potato planting were much greater with baskets with handles than with those carried on a strap.—M. B. Richards.

BARČIĆ, I. Prilog poznavanju utroška energije u poljoprivrednim radovima. 1. Potrošnja energije pri jesenjem oranju. [Energy exchange in agricultural tasks. 1. Energy output in autumn ploughing.] *Zborn. Rad., Srpsku Akad. Nauka*, 1954, **28** (Inst. Nutrit., No. 2), pp. 10. [Inst. Nutrit., Serb. Acad. Sci.] German summary.

Measurements were made with the Dortmund gas meter and the Haldane apparatus of the energy exchange of men ploughing generally flat land. There were 9 subjects whose basal metabolism ranged from 56.1 to 80.2 Cal. per hr. The averages for data from 13 estimations were : bodyweight 68.8 kg., R.Q. 0.79, energy exchange during work 319.4 Cal., and at rest 68.1 Cal. per hr., at an average speed of ploughing of 46.3 m. per minute. For a ploughman working for 8 hr. the daily energy requirement is estimated to be about 4100 Cal. (From summary).—D. Harvey.

WYNDHAM, C. H., STRYDOM, N. B., MORRISON, J. F., DU TOIT, F. D. and KRAAN, J. G. A new method of acclimatization to heat. *Arbeitsphysiologie*, 1954, **15**, 373-382. [Lab. Appl. Physiol., Transvaal and Orange Free State Chamber of Mines, Johannesburg.]

In a new method of acclimatization of labourers to the hot humid conditions experienced in deep mines, the men are exposed to full production rates in mild heat for 6 days, followed by 6 days at full production rates in very severe heat. In a test of the method on 205 labourers not one developed heat stroke. The men are productive from the start, and the method offers considerable economical, physiological and psychological advantages over the present procedure, lasting 18 to 28 days, where work is restricted during the initial stages of acclimatization.—M. B. Richards.

- KROG, H. and MONSON, M. Notes on the metabolism of a mountain goat. *Amer. J. Physiol.*, 1954, 178, 515-516. [Arctic Health Res. Centre, Pub. Health Serv., Anchorage, Alaska.]

A male mountain goat, *Oreamnos americanus*, aged $1\frac{1}{2}$ years, was captured in Alaska. Its oxygen consumption was fairly constant at environmental temperatures from 20° to -20° C., with a mean of 0.26 ml. oxygen per g. per hr. At -30° C. oxygen consumption rose by about 23 per cent., and at -50° C. by 130 per cent. The metabolic rate corresponds with the general formula $H=KW^2$, showing no modification for the cold environment of Alaska.—D. Duncan.

2190

- GELINEO, S. La température d'adaptation, la concentration de l'hémoglobine et la production de chaleur chez le chien. [Adaptation temperature, haemoglobin concentration and heat production in the dog.] *C.R. Soc. Biol.*, 1954, 148, 1114-1116. [Inst. Physiol., Fac. Sci., Univ. Belgrade.]

Three dogs aged 3 or 4 years received a diet of meat, bread, maize meal and milk. Oxygen consumption was measured in a closed circuit after they had fasted for 17 to 20 hr. The dogs spent $2\frac{1}{2}$ to 3 months at temperatures between -4° and $+5^{\circ}$ C., then 1 spent a month and the others 2

months at 25° C. and finally 2 spent another month at between 5° and 10° C.

These dogs adapted themselves by chemical thermoregulation. The basal metabolism at 25° C. and oxygen consumption at 3° C. were compared at the beginning and end of the period spent at 25° C. In dog "Noir" the B.M.R. fell from the first to the second estimation by 19 per cent. and heat production at 3° C. fell by 30 per cent. In dog "Djoka" the falls were 22 and 35 per cent., and in "Blanc" 28 and 38 per cent. Hb concentrations are tabulated: the mean value was 14.0 g. per 100 ml. after the low temperature period and 12.7 after the high.

The results are contrasted with those obtained by Irving (Title 3687, Vol. 21) in Eskimo dogs, which modified their heat loss rather than heat production.—D. Duncan.

- COTTLE, W. and CARLSON, L. D. Adaptive changes in rats exposed to cold. Caloric exchange. *Amer. J. Physiol.*, 1954, 178, 305-308. [Dept. Physiol. Biophys., Sch. Med., Univ. Washington, Seattle.]

Rats were fed on Purina chow and kept in a cold room at $5 \pm 1^{\circ}$ C.; controls were kept at $25 \pm 2^{\circ}$ C.

Young rats placed in the cold room maintained their rate of growth for about a week and then began to lag behind controls. Rats from the control group placed in the cold room after 28 days at 25° C. lost weight for about a week, and after this became and remained comparable in weight to other animals in the cold. All rats increased their food intake during their first week in the cold. Rats brought from 5° to 25° C.

immediately began to eat less, and their weight changed little.

Heat production of rats in the cold room rose abruptly during the first 5 days and continued to rise for 2 or 3 weeks; after about 5 weeks it began to decline. Cold-acclimatised rats equalled others in heat production at 25° C., but at 15° and 5° C. the former produced more heat.—D. Duncan.

2194

ROBINSON, K. W. Heat tolerances of Australian monotremes and marsupials. *Austral. J. Biol. Sci.*, 1954, 7, 348–360. [Dept. Physiol., Univ. Queensland, Brisbane.]

The species studied were platypus, echidna, bandicoot, possum (*Trichosurus caninus*), cuscus, koala, wallaby and wallaroo, and the animals were young, healthy adults. They were exposed for 7 hr. twice weekly to combinations of dry-bulb temperatures from 86° to 108.5° F. with absolute humidities between 15 and 40 mm. vapour pressure. Rectal temperature, pulse and respiratory rates, evaporative weight loss and behaviour were recorded.

The monotremes were but poorly able to regulate body temperature at air temperatures above 90.5° F., and the echidna was less tolerant of heat than the platypus. Rising humidity at 90.5° F. was relatively well tolerated by the monotremes. The animals higher in the evolutionary scale were better able to withstand the higher temperatures. Marsupials panted, monotremes did not.

The platypus became drowsy and inactive as its body temperature rose; the only method by which it can prevent overheating is by cutting down heat production. The marsupials, besides panting, lick themselves to procure evaporation. Sweating appears to be more efficient in the more

tolerant species, which approach eutherian mammals in ability to regulate temperature.

IRVING, E. M. and WANG, I. The effect of the previous diet on glucose tolerance tests. *Glasgow Med. J.*, 1954, 35, 275–278. [Dept. Metabol. Dis., Victoria Infirmary, Glasgow.]

The subjects, 7 men and 5 women from 19 to 25 years old, were healthy and of normal weight, except 1 who was 20 per cent. over ideal weight. Their normal diets provided from 150 to 420 g. carbohydrate daily. Oral glucose tolerance tests were made after 4 days on controlled diets providing 100 and 300 g. carbohydrate daily.

There was no significant effect of diet on fasting blood sugar levels or the shape of the curves except that in 3 subjects on the low intake curves were obtained in which the peak was above 180

mg. per 100 ml. It was concluded that it is unnecessary to give extra carbohydrate before tests.

HENNEMAN, D. H., ALTSCHULE, M. D. and GONCZ, R. M. **Carbohydrate metabolism in brain disease. 2. Glucose metabolism in schizophrenic, manic-depressive, and involutional psychoses.** *Arch. Int. Med.*, 1954, **94**, 402-416. [Lab. Clin. Physiol., McLean Hosp., Waverley, Mass.]

In psychotic patients the fasting blood concentrations of pyruvic, citric and α -ketoglutaric acids and of inorganic phosphate were normal. One-third of the patients showed significant elevations of true blood glucose and lactic acid concentrations. After ingestion of 100 g. glucose the psychotic patients showed a delay in the return of the glucose concentration to the fasting value, an excessive and prolonged rise in whole blood lactic acid (seen almost exclusively in patients with psychosis of recent onset), an increased and prolonged accumulation of pyruvic acid, and an increased and prolonged fall in serum inorganic phosphate. Plasma citric acid and α -ketoglutaric acid showed a rise instead of the fall characteristic of most normal subjects. The results after intravenous infusion of dextrose varied with the rate of infusion. The biochemical abnormalities found in psychotic patients after administration of glucose are similar to those in patients with organic brain disease.

ALBANESE, A. A., ARNOLD, W. H., HAYS, D. R., BELMONT, A., ORTO, L. and DI LALLO, R. **Protein-sparing action of intravenously administered carbohydrate solutions.** *Metabolism*, 1954, **3**, 523-529. [Nutrit. Res. Lab., St. Luke's Hosp., New York.]

The patients who were given the solutions ranged from 13 to 80 years of age and were malnourished, in acute or convalescent phases of disease. The sugars and their concentrations were: invert sugar 10 per cent., or glucose or fructose, 5 or 10 per cent., and the amounts were between 0.5 and 3 litres daily. In 5 days the diet supplied 70 g. protein and 2000 Cal., with 14, 40 and 46 per cent. from protein, carbohydrate and fat, respectively.

The findings on protein-sparing action as measured by changes in excretion of N were difficult to evaluate. At 50 and 100 g. levels fructose solutions induced greater retention than did an invert sugar solution with a comparable amount of fructose. With 150 g. fructose in 5 per cent. fructose or in 10 per cent. invert sugar solutions, sparing of N was good, but as 10 per cent. solution its action was poor. Solutions of invert sugar, 10 per cent., or of fructose, 5 per cent. are those of choice; the final decision will rest on relative costs and availabilities.—D. Harvey.

2207

BEAL, J. M. and SMITH, J. L. (with FELTS, J.) **The metabolism of fructose in man.** *Surgery*, 1954, **36**, 243-255. [Surg. Serv., Veterans Admin. Centre, Los Angeles, Calif.]

In man intravenous injection of fructose commonly results in elevation of blood glucose as well as of blood fructose. In 8 experiments injection of fructose was followed by a mean rise in blood lactic acid from 8.3 to 38.4 mg. per 100 ml.; after glucose the level rose only to 10.8 mg. per 100 ml. CO_2 combining power of the blood fell. Serum inorganic P fell by about 2.7 mg. per 100 ml. after fructose and 1.5 mg. after glucose, and the effect on Mg was similar; Na, K and Cl levels were unchanged.

The amounts of sugars appearing in the urine after fructose administration need more study,

as reports are conflicting. Losses of P and N were greater after fructose than after glucose. In 3 patients glucose given into the portal vein was better retained than fructose, and losses of Na and K were greater with the latter. The higher electrolyte loss may seriously reduce the value of fructose for parenteral feeding.—D. Duncan.

2208

WALTON, J. N. and LATNER, A. L. **Ribosuria in muscular dystrophy.** *Arch. Neurol. Psychiat., Chicago*, 1954, **72**, 362-364. [Dept. Med., King's Coll., Univ. Durham.]

The test for *D*-ribose in the urine, suggested by Orr and Minot (*Arch. Neurol. Psychiat.*, 1952, **67**, 483) as diagnostic of muscular dystrophy, was made on 94 patients. Of 89 with muscle disorders of several types only 12 excreted ribose, which was excreted also by 2 patients with muscular atrophy caused by motor neurone disease.

It is concluded that the test has no value in the diagnosis of muscle disorders.—D. Duncan.

2209

TOUSTER, O., HUTCHESON, R. M. and REYNOLDS, V. H. **The formation of L-xylulose in mammals and its utilization by liver preparations.** *J. Amer. Chem. Soc.*, 1954, **76**, 5005-5006. [Dept. Biochem., Sch. Med., Vanderbilt Univ., Nashville, Tenn.]

The urine of normal guineapigs and of 3 normal human subjects contained no xylulose. The urine of a fourth subject contained this pentose, as did the urine of all 4 and of guineapigs after ingestion of *D*-glucuronolactone. Guineapig liver slices and homogenates utilised L-xylulose as rapidly as fructose.

It is suggested that xylulose is a normal metabolite which is poorly utilised in pentosuria, in which disorder it is excreted.—D. Duncan.

2210

APPEL, W., HANSEN, K. J. and ALSLEV, J. Untersuchungen über den Wirkungsbereich des Glukagons. [Studies of the range of activity of glucagon.] *Ztschr. ges. exp. Med.*, 1954, **124**, 345-354. [Med. Klin., Univ. Kiel.]

Blood sugar and cholesterol esters, lipid P, lactic and pyruvic acids, and amino-N in the serum were estimated in groups of about 10 subjects free from metabolic or liver disorder at intervals after they were given 2.5, 5.0, 10 or 20 μ g. per kg. bodyweight of a preparation of glucagon almost free of insulin and with about one-fifth of the activity of the crystalline substance.

Blood sugar rose rapidly to a peak after 15 min.; the most effective amount of glucagon was 2.5 μ g. per kg. bodyweight. In magnitude the effect of glucagon was similar to that of insulin, but it

did not last so long. Glucagon did not alter the arterio-venous difference in blood sugar. Lactic and pyruvic acids rose slightly but not significantly after 10 and 20 μ g. glucagon per kg. bodyweight. In contrast to insulin, glucagon did not affect blood amino-N or blood lipids.

The conclusions are that maintenance of normal blood sugar values depends on both glucagon and insulin; that glucagon, unlike other hormones antagonistic to insulin, has no effect on peripheral sugar utilisation; that it probably does not favour the formation of sugar from fat; and that it is unlikely to be responsible for the raised blood sugar in diabetes. It is regarded, not as an antagonist of insulin, but as a synergist which releases sugar from the liver.—W. M. Deans.

FOURNIER, P. **Aperçus nouveaux sur la physiologie des glucides, deduits de leur activité différente vis-à-vis de l'utilisation du calcium.** [New views on the physiology of carbohydrates deduced from their different activities in utilisation of calcium.] *C.R. Acad. Sci.*, 1954, **239**, 718-720.

The effects of sugars upon the retention of Ca were compared by the method described earlier (Abst. 745, Vol. 25) with groups of 6 young rats each weighing about 50 g.

Sucrose 12 per cent., glucose 20 per cent. and maltose 15 per cent. gave about the same utilisation of dietary Ca as the control diet with 85.5 per cent. starch. Lactose, *D*- and *L*-xylose and *D*- and *L*-arabinose each doubled the coefficient of Ca utilisation.

It is suggested that carbohydrates are divisible into 2 groups with different functions in the animal body. Starch, glucose, fructose, maltose and sucrose are "energetic" carbohydrates; but lactose, galactose, xylose and arabinose are considered to be structural carbohydrates, influencing bone formation. It is pointed out that many of the latter also form structural carbohydrates in plants in the forms of xylans, cellulans, hemicelluloses and pectic substances.—D. Duncan.

2214

DREINBACH, L. and NASSET, E. S. Absorption of carbohydrate and protein as affected by feeding cornstarch, banana, or glucose. *J. Nutrition*, 1954, **53**, 523-532. [Dept. Physiol., Sch. Med. Dent., Univ. Rochester, N.Y.]

Groups of 8 adult rats were given 3 diets of which 58 per cent. was carbohydrate in the form of maize starch, banana powder or glucose, 18 per cent. protein, 20 per cent. fat and 4 per cent. salts supplemented with vitamins A, D, E, K and those of the B group. A fourth diet had no protein and contained 78 per cent. maize starch. The diets were given for 5 days, followed by a 48-hr. fast to empty the digestive tract; the rats then received 1.5 to 2.5 g. diet; and the amount eaten was estimated by difference. Pairs of rats from each group were killed 2, 3, 4 and 5 hr. later and the contents of the digestive tract were analysed for carbohydrate and protein. The procedure was repeated 3 times for each diet.

The carbohydrates of banana and glucose were absorbed most rapidly in the second hour; starch absorption reached a maximum in the third hour. In the third and fourth hours more starch was absorbed than banana carbohydrate or glucose, but the percentage of starch absorbed was significantly less than of banana carbohydrate or glucose. The absorption of ingested protein was not readily ascertained; in every experiment except one the protein recovered was more than the amount ingested. The recovered protein was corrected by subtracting the amount of protein present after administration of the protein-free diet; "absorbed" protein was obtained by subtracting "corrected" recovered protein from ingested protein.

KIMBEL, K. H., BÜNTE, H., HEISE, E. and FISCHER, W. Untersuchungen über enterale Antibiose bei der Ratte. 3. Beeinflussung der Kohlenhydratesorption. [Studies on intestinal antibiotics in the rat. 3. Effect on carbohydrate absorption.] *Ztschr. ges. exp. Med.*, 1954, **124**, 342-344. [Med. Klin., Univ. Erlangen.]

For parts 1 and 2 see Abst. 4382, Vol. 24.

Carbohydrate absorption was studied by Cori's method in rats given terramycin or sulphaguanidine. In rats given 25 mg. terramycin daily for 12 or 16 weeks sugar absorbed in an hour was reduced to 64.5 per cent., and in those given 200 mg. sulphaguanidine daily for 16 weeks to 74 per cent. of the normal. Since the antibiotic and sulphaguanidine had a similar effect, the cause of the diminished absorption is assumed to be a change in the flora, and consequently in vitamin synthesis, in the intestine. Daily intraperitoneal injection of 25 mg. pyridoxine or 15 mg. folic acid for 8 weeks in

rats receiving terramycin appeared to improve absorption slightly, but vitamin B₁₂ given intraperitoneally and folic acid by mouth were without effect. These results indicate that earlier records of flattening of the blood sugar curve after glucose in rats given antibiotics are to be explained by decreased absorption of sugar in the intestine, and not by increased uptake of sugar by the liver.

SCOW, R. O. and CORNFIELD, J. Effect of thyroidectomy and food intake on oral and intravenous glucose tolerances in rats. *Amer. J. Physiol.*, 1954, **179**, 39-42. [Lab. Biochem. Nutrit., Nat. Inst. Health, Bethesda, Md.]

In earlier work (Abst. 5060, Vol. 21) the effect of thyroid removal on glucose tolerance was thought to be secondary to the effect on body size.

Rats had their thyroids and parathyroids removed or a sham operation when they were 21 to 27 days old. They were divided into 5 groups and received a complete purified diet; group 1, sham-operated rats fed to appetite; group 2, operated rats fed by tube with amounts nearly equal to those eaten by the first group; group 3, operated rats fed to appetite; group 4, pair-fed with group 3 but sham-operated; and group 5, pair-fed with group 2 but sham-operated. Glucose tests were not made for 45 days or more after the operations, so sham-operated rats can be called normal controls. Each animal had oral and intravenous tests, the former usually 7 to 10 days before the latter.

In oral tests the blood sugar rose higher in operated rats than in controls, whatever the method of feeding, but the curve was not prolonged in time. In intravenous tests there was marked impairment of tolerance after thyroid removal. The blood sugar value at 60 min. was about twice as high in operated rats as in controls and among the former it was higher in force-fed rats than in those fed to appetite. Removal of injected

glucose from the blood did not begin until 20 min. after injection in operated animals, and the slow fall which then began appeared to be due to urinary excretion of the glucose.—D. Duncan.

MELI, A. and FRANCESCHINI, J. Ricerche sul metabolismo del glicoso-1-fosfato nei ratti normali e diabetici. [Metabolism of glucose-phosphate in normal and diabetic rats.] *Arch. Sci. biol., Bologna*, 1954, **38**, 463-468. [Lab. Biol., Ist. "Carlo Erba", Milan.]

Glucose-1-phosphate or glucose was given by intravenous injection at the rate of 100 mg. per 100 g. bodyweight to rats weighing 100 to 150 g., which had been rendered diabetic by injection of alloxan. The blood sugar levels 20 and 120 min. after injection were similar with both substances.

Similar diabetic rats also weighing 100 to 150 g. received glucose-1-phosphate similarly or glucose immediately followed by insulin given intraperitoneally. Oxygen consumption and CO_2 production were measured for 1 hr. Glucose and insulin significantly elevated the R.Q., but glucose-1-phosphate did not.

In isolated diaphragm muscle taken from normal and alloxan-diabetic rats, glucose-1-phosphate produced greater oxygen consumption than did glucose.

It is concluded that glucose-1-phosphate favoured, not increased utilisation of glucose, but an increase in other oxidative processes.—D. Duncan.

PATRICK, S. J. (with WEISZ, T.) Effect of hypoglycin A on liver glycogen with a method for the study of changes in liver glycogen. *J. Appl. Physiol.*, 1954, **7**, 140-142. [Div. Biochem., Dept. Physiol., University Coll. W. Indies, Jamaica.]

Hypoglycin A is a compound isolated by Hassall *et al.* (*Nature*, 1954, **173**, 356) from the ackee (*Blighia sapida*), one of the foods held responsible for vomiting sickness in Jamaica.

Biopsy specimens of liver from 4 patients acutely ill with vomiting sickness contained less than 0.7 per cent. of their wet weight as glycogen. Samples from recovered patients and from undernourished children contained 3 to 10 per cent. glycogen.

Intramuscular injection of hypoglycin A, 250 mg. per kg. bodyweight, into rats reduced liver glycogen to 0.2 per cent. of the wet weight or less in 4 to 6 hr. Blood sugar rose at first, but fell very low as liver glycogen became exhausted. In rats given glucose by vein, hypoglycin A prevented formation of glycogen in the liver, and the blood sugar fell more slowly than in normal rats.

LUFU, C. I. and FARBER, E. Effects of ethionine upon hepatic glycogen formation from glucose in intact rats. *Proc. Soc. Exp. Biol. Med.*, 1954, **86**, 701-705. [Dept. Pathol., Sch. Med., Tulane Univ., New Orleans, La.]

In the first experiment groups of male and female rats were fasted for 24 hr. and were then given 2.5 g. glucose in 3 ml. water by stomach tube. Individual groups received 0.75 mg. DL-ethionine per g. bodyweight by intraperitoneal injection, half at the same time as the glucose, half 2 hr. later; DL-methionine in the same way; a mixture of methionine and ethionine; or saline. They were fasted and killed 6 hr. after receiving the glucose. The second experiment was similar, but 1.3 g. glucose in all was given subcutaneously in 4 doses at intervals of an hour and the rats were killed 6 hr. after the first dose. In the third experiment glucose was given either by mouth or subcutaneously, ethionine or saline was given 3 hr. after the initial dose of glucose and the rats were killed 4 hr. later.

Female rats injected with ethionine had almost no liver glycogen 6 hr. after receiving glucose by mouth; males had more, but still much less than controls. In both sexes there was delayed absorption of glucose. When the glucose was given subcutaneously there was less difference between the sexes, but both had less liver glycogen after ethionine than after methionine or saline. In the third experiment the females given ethionine had less liver glycogen 7 hr. after being given glucose, though controls killed at 3 hr., before the survivors received ethionine, had laid down appreciable amounts of glycogen. The males showed little or no effect of ethionine in this experiment.

Methionine partly prevented the losses of liver glycogen, but it acted like ethionine in delaying absorption of glucose. There is no known meta-

bolic function of methionine which readily explains these findings.—D. Duncan.

ROSE, W. C., COON, M. J. and LAMBERT, G. F. The amino acid requirements of man. 6. The rôle of the caloric intake. *J. Biol. Chem.*, 1954, **210**, 331-342. [Div. Biochem., Noyes Lab. Chem., Univ. Illinois, Urbana.]

For part 5 and references to earlier parts, see Abst. 3316, Vol. 24.

Nitrogen balance was measured in 3 subjects receiving artificial diets of different energy value containing either casein, acid or enzymically hydrolysed casein or mixtures of purified amino-acids equivalent to the constant amount of about 10 g. N daily. The subjects weighed 65, 71 and 73 kg.

Whole casein maintained N balance at an energy value of 35 Cal. per kg. bodyweight. At this energy level acid-hydrolysed casein supplemented with tryptophan produced in 2 subjects a negative balance which was corrected by raising the energy intake to 45 Cal.; there was approximate equilibrium in the third. A mixture of the 8 essential amino-acids plus glycine and urea or a mixture in correct proportion of all the component amino-acids in casein produced a similar effect and seemed inferior to acid-hydrolysed casein with respect to the energy required for N balance. The enzymic appeared to be slightly superior to the acid preparation.

The data showed that a diet containing mixtures of amino-acids required a higher energy intake than the equivalent amount of casein for N balance.

CALLOWAY, D. H. and SPECTOR, H. Nitrogen balance as related to caloric and protein intake in active young men. *Amer. J. Clin. Nutr.*, 1954, **2**, 405-412. [Quartermaster Food and Container Inst. Armed Forces, Chicago, Ill.] Spanish summary.

From a review of the literature it is concluded that in young, normal, active men whose energy intake is adequate 8.5 g. N gives balance and there is little additional storage of N even with greatly increased protein intakes. Negative N balance is greatest when intake is 700 non-protein Cal. daily and protein is not noticeably spared when intake is as high as 2800 Cal. daily in the absence of protein from the diet. It is suggested that a food "unit" of 500 Cal. daily would be of use as a guide in the

compounding of a military survival ration or for short-term civilian emergency feeding.

PULLMAN, T. N., ALVING, A. S., DERN, R. J. and LANDOWNE, M. The influence of dietary protein intake on specific renal functions in normal man. *J. Lab. Clin. Med.*, 1954, **44**, 320-332. [Dept. Med., Univ. Chicago, Ill.]

Each of the clinically normal young subjects, 5 women and 15 men, was studied after 2 weeks on each of 3 diets, which provided about 2.6, 1.0 and 0.3 g. protein per kg. bodyweight daily. For each subject the diets were isocaloric and were designed to maintain constant bodyweight, and for half the subjects the salt intake was also constant. Glomerular filtration rates were estimated by inulin clearance. Effective renal plasma flow was estimated by Diodrast clearance in 10 subjects and by *p*-aminohippurate (PAH) clearance in the others; maximum tubular secretory capacity for PAH was also studied in the latter. Water diuresis was induced in all studies.

Glomerular filtration rates were significantly higher on the high protein intake and lower on the low protein intake than on the medium protein intake, but they remained within the normal range. Similar changes occurred in effective renal plasma flow, though the reduction on the low-protein diet failed to reach statistical significance. Changes in filtration fraction were negligible. Maximum tubular secretory capacity was increased on the high and decreased on the low protein intake, but the ratio of plasma flow to secretory capacity was inversely affected. It is not known whether this represents true ischaemia on the high- and hyperaemia on the low-protein diet.—D. Duncan.

BLOCKER, T. G., LEVIN, W. C., LEWIS, S. R. and SNYDER, C. C. The use of radioactive sulphur labeled methionine in the study of protein catabolism in burn patients. *Ann. Surg.*, 1954, **140**, 519-523 (with discussion 523). [Dept. Surg., Univ. Texas Med. Branch, Galveston.]

The subjects were 14 "normal" patients without burns and 10 with burns of 10 to 72 per cent. in extent. Each received by vein 80 to 100 μ C. of 35 S-methionine and blood samples were collected before this and at intervals afterwards. The activity of total serum, total protein and globulin was estimated.

In the control subjects the peak of serum radioactivity occurred 3 to 5 hr. after the injection, when the plasma contained about 7 per cent. of the injected radioactivity. The serum radioactivity fell gradually in the next 4 days to about half its peak value. At this time 95 to 99 per cent. of the serum activity was in the protein. Between the fourth and the 21st days the decline in serum activity was negligible, suggesting that the labelled methionine was in equilibrium with the body protein pool.

In 3 patients either relatively slightly burned or studied very long after being burned the results were similar to those in the normal group. In the rest the drop from the peak level of serum activity was more rapid, the plateau value was only 8 to 30 per cent. of the peak and in some the activity continued to decline until the 21st day.

It is suggested that the results indicate a rapid breakdown of body proteins after extensive burns.

SCHØNHEYDER, F., HEILSKOV, N. S. C. and OLESEN, K. Isotopic studies on the mechanism of negative nitrogen balance produced by immobilization. *Scand. J. Clin. Lab. Invest.*, 1954, **6**, 178-188. [Biochem. Inst., Univ. Aarhus, Denmark.]

Three healthy men on a diet which normally maintained N equilibrium were immobilised in bed by a plaster of paris bandage extending from the umbilicus to the toes. After about 5 days the N balance became negative, reaching a minimum at the tenth day and then increasing somewhat. At about the tenth day, 15 N-glycine was given by mouth and the excretion of 15 N in the urine was followed for 5 days. Excretion was much faster than when the subjects were not immobilised. The results were examined mathematically as were those described in Abst. 756, Vol. 25, and indicated

that one of the model pool systems considered then led to most unlikely conclusions, but the other model gave consistent results.

According to this model, dietary N first enters pool P, of amino-acids and other compounds available for synthesis. This pool is in equilibrium with pool Q of metabolically active proteins of the plasma and internal organs, and with the large relatively stable pool V of the proteins of muscle, skin and connective tissue. N flows from pool P to pool U, the total N-containing system of the urine, and is then excreted.

Consideration of the results according to this model suggested that the negative N balance during immobilisation was primarily due to reduced synthesis of tissues proteins of pool V, while their rate of breakdown remained unchanged. The calculated sizes of pools P, Q and U were little changed by immobilisation.—C. Warner.

2231

BLAINEX, J. D. High protein diets in the treatment of the nephrotic syndrome. *Clin. Sci.*, 1954, **13**, 567-581. [Dept. Exp. Pathol., Univ. Birmingham.]

One male and 2 female patients were studied. At protein intakes varying from 97 g. to 205 g. daily, N balance was measured, serum protein fractions were estimated by electrophoresis on paper and the clinical state of each patient was assessed; urine protein and N.P.N. excretion was studied in detail and the daily loss of urea, ammonia, creatinine and other N.P.N. was estimated. Each protein intake was maintained for 9 days or longer; several periods of low protein intake concluded the study.

Positive N balances were obtained in all 3 patients with the high-protein diets and were maintained over long periods. Increased N intake produced an increase in N balance. In the 3 patients the daily output of urea was abnormally low before the start of the studies; high protein feeding produced only a slight rise in urea excretion. In one patient a rise in urine N.P.N. in excess of the rise in urea N was associated with abnormal loss of amino-acids. It is concluded that owing to the severe body protein deficiency which occurs in the nephrotic syndrome prolonged high protein intakes are necessary in treatment. The history of each patient is given in an appendix.

2232

AUBERTIN, E., RIVIÈRE, J., LOISEAU, P., DEBOT, P. and MALINEAU, R. Effect of high plant protein regimens on the liver of dogs. *Amer. J. Clin. Nutr.*, 1954, **2**, 413-421. [Dept. Clin. Med., Fac. Med., Bordeaux.] Spanish summary.

Six dogs were maintained for 3½ months on a diet containing, in addition to vitamins and salt, about 165 g. protein and 185 g. carbohydrate provided by 250 g. bread, 200 g. lean horsemeat, and 200 g. peanut meal for 2 dogs, soya meal for 2 and sunflower seed meal for the other 2. In all 6 liver function tests revealed serum disturbances, particularly in the Gros and Kunkel tests, the serine:globulin ratio, fibrinogen, blood lipid, total cholesterol, free and ester cholesterol, cholinesterase and sulphophosphovanillic reaction (see Chabrol *et al.*, *Sem. Hôp. Paris*, 1949, p. 3446); liver biopsies revealed evidence of modifications of the mitochondria only. The diet was later modified; bread was reduced to 100 g., meat was reduced, then eliminated, and meal was raised to 400 g. and to 500 g. daily; the diet was finally composed of 260 g. protein and 200 g. carbohydrate. Under these conditions great differences were observed.

In the 2 dogs which received peanut meal there was rapid fatty degeneration of the liver; soya meal caused a similar though slower change, which led eventually to the development of annular cirrhosis; sunflower seed meal produced only modifications of the mitochondria. In one dog which received a peanut meal diet supplemented with vitamins, methionine, choline and inositol the toxicity of the diet was not less.

It is concluded that these meals, which are prepared from the oil-free residues of peanut, soya and sunflower seed, are not to be recommended in the diet of patients with liver disease.

LAL, B. M. and RAJAGOPALAN, R. **Studies on mutual supplementation in vegetable proteins.** *Indian J. Med. Res.*, 1953, **41**, 173-183. [Food Technol. Lab., Dept. Biochem., Indian Inst. Sci., Bangalore 3.]

The biological value of 7 mixtures each consisting of 3 vegetable proteins in different proportions was estimated using 2 groups, each of 3 male and 3 female rats. The mixtures were groundnut, wheat and cottonseed; groundnut, sesame and cottonseed; groundnut, yeast and cottonseed; groundnut, wheat and yeast; groundnut, soya bean and sesame; groundnut, cottonseed and copra; groundnut, yeast and copra. One group of rats was used to evaluate 4 mixtures and the other group for the other 3 mixtures. Endogenous N excretion was estimated with an N-free diet of maize starch 71, sucrose 10, coconut oil 10, vitaminised starch 5 and salt mixture 4 per cent. The composition of the experimental diets was sucrose 10, coconut oil 10, mixture to provide 10 per cent. protein 5, vitaminised starch 5, salt mixture 4 per cent., with maize starch to 100 per cent. The

diets were given for 7-day periods; faeces and urine were collected for estimation of N during the last 4 days of each period.

Although the first and fifth mixtures had fairly high biological values the other mixtures had almost the same biological value as the individual proteins. The net protein values of the mixtures were considerably higher than those of common cereals and pulses and compared favourably with those of animal proteins. No significant difference was found between the essential amino-acid content of the mixtures with low biological values and that of the mixtures with high biological values. An explanation of the results on the basis of length of time and rate of liberation of the essential amino-acids is discussed.—G. F. Garton.

2234

CHATTOPADHYAY, H. and BANERJEE, S. **Effect of germination on the biological value of proteins and the trypsin-inhibitor activity of some common Indian pulses.** *Indian J. Med. Res.*, 1953, **41**, 185-189. [Dept. Physiol., Presidency Coll., Calcutta.]

The biological value for young rats of the proteins of 5 pulses, *Cicer arietinum*, *Phaseolus mungo*, *Lens esculenta*, *Phaseolus radiatus* and *Pisum sativum*, was estimated before and after 48 hours' germination at room temperature. The average increase in weight per g. protein consumed was taken to be the biological value of the protein for growth. The trypsin-inhibitor activity of the 5 pulses and that of another variety of *Cicer arietinum* was estimated also before and after 48 hours' germination.

The biological value of proteins of *Cicer arietinum*, *Phaseolus mungo* and *Lens esculenta* increased after germination, that of proteins of the other 2 pulses decreased. The trypsin-inhibitor activity of all 6 pulses was unchanged by germination, so it is not responsible for the altered biological values.

MERKEL, H. and DONTENWILL, W. Die Wirkung chronischer parenteraler Eiweisszufuhr auf Blut und blutbildendes Gewebe. [The effect of prolonged parenteral administration of protein on the blood and haemopoietic tissue.] *Frankfurter Ztschr. Pathol.*, 1954, **65**, 323-329. [Pathol. Inst., Univ. Kiel.]

Of 40 white mice given daily subcutaneous injections of "Nutrose", 20 were killed after 28 days and the rest after 28 weeks. In all the total leucocyte count increased sharply in the first 2 weeks, but segmented polymorphs by only 9.25 to 17.8 per cent. The lymphocytosis generally regressed between the third and ninth weeks, but seldom reached the normal. A further increase occurred in some after about 17 to 22 weeks. The lymphocyte curve ran almost exactly parallel to the total leucocyte curve, the increase averaging 71.5 to 87 per cent. Binucleated lymphocytes and mitoses were present in small numbers. Plasma cells were not found. It is assumed that in the white mouse their function is exercised by lymphocytes. At the end of the experiment spleen and lymph nodes showed neither injury nor hyperplasia. The bone marrow presented the picture of increased activity. A small amount of amyloid was present in the liver in 3 mice. According to these findings the mice had adapted themselves successfully to the prolonged administration of foreign protein.—M. B. Richards.

VÁRDI, P. (with TATÁR, I.) Studies on protein metabolism. 1. Correlation between dietary protein and stored protein as determined on the basis of changes in urinary nitrogen. *Acta physiol. hung.*, 1954, **6**, 313-320. [Inst. Nutrit. Sci., Budapest.] Russian summary.

Rats were depleted of N for 4 days, then given a test diet for 2 days and the low protein diet again. All diets contained dried yeast. Urinary N was measured during the 24 hr. before and after protein regeneration; the difference between these 2 values was called the "restitution N". There was a linear relation between restitution N and the amount of casein in the test diet up to 18 per cent. casein. Whole egg protein gave much higher and meat moderately higher restitution N values than casein; potatoes and a mixed, mainly vegetable, diet gave values similar to casein. It is concluded that urinary N excretion during the

post-regeneration protein-free periods depends primarily on the extent of restitution of protein stores by the test protein.—C. Warner.

2239

JEHOTTE, J. Etude de l'équilibre azoté chez le rat soumis à une irradiation létale. [Nitrogen equilibrium in the rat under lethal irradiation.] *C.R. Soc. Biol.*, 1954, **148**, 941-943. [Lab. Pathol. Anat., Univ. Liège.]

After lethal exposure of rats to X-rays their food consumption and N excretion dropped to a low level, rising again after about 4 days; N excretion, but not food consumption, fell again before death. Starvation did not alter the pattern of N excretion; starved, non-irradiated animals showed the fall and secondary rise of N excretion, but not the second fall.—C. Warner.

2240

ASCHKENASY, A. Action des protéines et de certains acides aminés alimentaires sur la survie de rats surrenalectomisés. Protection de ces rats contre l'effet léthal d' inanition protéique par la cortisone. [Effect of proteins and certain dietary amino-acids on the survival of adrenalectomised rats. Protection of such rats against the lethal effect of protein deficiency by cortisone.] *C.R. Acad. Sci.*, 1954, **239**, 1000-1002.

Adrenalectomised rats given a protein-free diet and 1 per cent. NaCl to drink survived much longer when cortisone was given by mouth; deoxycorticosterone had a smaller effect. Addition of protein to the diet also increased survival, 18 per cent. casein giving the best response. Single amino-acids, especially methionine, valine, lysine, tryptophan or threonine, also increased survival.

C. Warner.

LINAZASORO CALVO, J. M. Accion de los androgenos sobre la retencion de nitrogeno en los animales nefrectomizados. [Effect of androgens on nitrogen retention in nephrectomised animals.] *Rev. clín. española*, 1954, **54**, 8-9. [Inst. Invest. Méd., Madrid.] English, German and French summaries.

Nitrogen retention was studied in adult rats, males, females and castrated males, normal or 48 hr. after removal of the kidneys.

The increase in N retention after kidney removal was greater in females than in males and so was the production of urea N. In castrated males the values approached those observed in females, but injection of testosterone made castrated males comparable to males in this respect. Injection of testosterone into females did not reduce the increases in protein breakdown.—D. Duncan.

WINJE, M. E., HARPER, A. E., BENTON, D. A., BOLDT, R. E. and ELVEHJEM, C. A. **Effect of dietary amino acid balance on fat deposition in the livers of rats fed low protein diets.** *J. Nutrition*, 1954, **54**, 155-166. [Dept. Biochem., Univ. Wisconsin, Madison.]

Many groups each of 6 weanling rats were fed to appetite for 2 weeks on low-protein diets supplemented as required with amino-acids; the proteins included defatted and dried pork and beef, egg albumin and fibrin. At the end of the experiment liver fat was estimated by ether extraction.

Fat accumulated in the livers of the animals given the low-protein diets; as the dietary level of each protein rose the amount of fat deposited in the liver decreased. No fat accumulated in liver in the groups fed on diets low in fibrin. When the pork, beef or albumin diets were supplemented with gelatine, fibrin or threonine plus glycine the amount of liver fat deposited was reduced. In rats given the low-protein diet containing egg albumin, lysine in the presence of histidine and threonine further decreased the amount of liver fat deposited.—G. A. Garton.

CANNON, P. R., FRAZIER, L. E. and HUGHES, R. H. **Fat emulsions as caloric supplements in parenteral nutrition, with particular reference to amino acid utilization.** *J. Lab. Clin. Med.*, 1954, **44**, 250-260. [Dept. Pathol., Univ. Chicago, Ill.]

Protein-depleted rats were repleted by daily subcutaneous injections of protein hydrolysate while being fed on a diet providing only 12 Cal. daily, but adequate in salts, vitamins and roughage; 10 to 15 per cent. fat emulsion in 5 per cent. glucose solution, stabilised with Tween 60, were given intraperitoneally or intravenously to some animals, providing 20 Cal. daily. The fat was absorbed and utilised well. The animals receiving fat increased in weight, body water and body protein; those not receiving fat maintained weight for about 8 days, during which they lost about 70 per cent. of their body fat, then lost weight rapidly.—C. Warner.

OKREY, R. and LYMAN, M. M. **Dietary constituents which may influence the use of food cholesterol. 2. Protein, L-cystine and DL-methionine intake in adolescent rats.** *J. Nutrition*, 1954, **53**, 601-611. [Dept. Home Econ., Univ. California, Berkeley.]

Groups of 10 male and 11 female immature rats were used. One group was given the basal diet

of vitamin-free casein 5, egg albumin powder 10, fat 13.5, salt mixture 4, cholesterol 1, sucrose 64.5, a mixture of A, D, E and K vitamins 1 and a mixture of B group vitamins 1 per cent. The other 4 groups received the same diet with 15 per cent. more egg albumin or 0.9 per cent. DL-methionine or 0.3 per cent. L-cystine or 0.9 per cent. DL-methionine plus 0.3 per cent. L-cystine. After 21 days the rats were killed and liver tissue was removed for moisture estimation and lipid analysis.

The male rats which received extra egg albumin had significantly less liver cholesterol than those given the basal diet. Females had consistently less liver cholesterol than males, but showed no significant decrease with the increased egg albumin intake. DL-Methionine tended to decrease liver cholesterol content and L-cystine to increase it; differences were significant for the female rats only and were related to gain in bodyweight. These sex differences in response to both protein and cholesterol were so marked that it is essential to make separate evaluations for males and females.

EDWARDS, W. H. and WILSON, W. O. **Relationship of hyperthermy to nitrogen excretion in chickens.** *Amer. J. Physiol.*, 1954, **179**, 76-78. [Dept. Poultry Husb., Univ. California, Davis.]

Laying hens after being kept at 60° F. for about a week were starved for 20 hr. before blood and urine samples were collected; in some tests birds were kept at 90° or 100° F. for 1½ hr. to induce hyperthermy. The body temperatures of the birds at the 3 environmental temperatures were 105°, 110° and 112° F.

In 5 starved birds the uric acid N of the urine as a percentage of the total N.P.N. decreased significantly in hyperthermy; N.P.N., uric acid, purine and amino-acid N were increased irregularly, but not significantly. The blood uric acid N and percentage of uric acid in N.P.N. decreased significantly and purine N and percentage of purine in N.P.N. increased greatly. In 5 fed birds the changes in uric acid N were similar but the increase in purine N was slight.

It is suggested that overheating may affect some enzyme system necessary to convert purines to uric acid, especially in fasted birds.—D. Duncan.

Hsia, D. Y. Y., Hsia, H. H., Green, S., Kay, M. and Gellis, S. S. **Amino-aciduria in galactosemia.** *Amer. J. Dis. Child.*, 1954, **88**, 458-465. [Dept. Paediat., Beth Israel Hosp., Boston, Mass.]

Two brothers aged $3\frac{1}{2}$ and 2 years were the subjects and studies of amino-N in blood serum and urine were made on 3 separate occasions, (1) while on galactose-free diet, (2) after 50 g. *d*-galactose had been included in the diet for 10 days, and (3) after galactose had been discontinued for 10 days. Similar studies were made of both parents (1) while on normal diet without added galactose, and (2) after 75 g. *d*-galactose had been taken daily for 10 days. In blood and urine α -amino-N was estimated and in urine the amino-acid pattern was studied chromatographically. While the children were on a galactose-free diet the amount of amino-N in the urine was similar to that in the urine of normal children, but when galactose was given there was an increase between two- and three-fold. The increase was general, no single amino-acid being present in relatively excessive amount. The metabolism of α -amino-N in the parents was normal.

Possible pathways for the appearance of these increased amounts are discussed.—D. Harvey.

DENT, C. E., HEATHCOTE, J. G. and JORON, G. E. **The pathogenesis of cystinuria. 1. Chromatographic and microbiological studies of the metabolism of sulphur-containing amino-acids.**

DENT, C. E., SENIOR, B. and WALSHE, J. M. 2. **Polarographic studies of the metabolism of sulphur-containing amino-acids.** *J. Clin. Invest.*, 1954, **33**, 1210-1215; 1216-1226. [Med. Unit, University Coll. Hosp. Med. Sch., London.]

1. The subjects were a normal man and woman and 2 men with cystinuria. In separate tests each subject received, fasting, 5 g. L-cystine, 6.2 g. DL-methionine or 6.5 g. L-cystine hydrochloride, drunk dissolved or suspended in water. Blood and urine samples were taken at intervals for 7 hr. Amino-acids were estimated microbiologically and chromatographically.

In no subject was plasma cystine appreciably increased after ingestion of cystine, and there was no change in urinary cystine output. Methionine produced no consistent change in plasma cystine, but plasma and urinary methionine were increased in all subjects. After cystine plasma and urinary cystine rose considerably in all subjects, the latter especially in the cystinurics. Plasma α -amino-n-butyric acid rose in all subjects after methionine, and in one of the cystinuric subjects also after

cystine and cysteine. In no experiment was plasma or urinary lysine or arginine affected.

On ordinary hospital diet the cystinuric subjects excreted in urine 800 to 900 mg. cystine in 24 hr.

The results support the theory that the cystine output is increased in cystinuria because of a low renal threshold for cystine or kidney tubule dysfunction, and not because of any more general "error of metabolism".

2. The experiments described in the preceding paper were extended to 9 normal adults, 6 cystinuric adults, 1 cystinuric child and an apparently healthy adult who yet excreted 120 to 180 mg. cystine in 24 hr. and was regarded as heterozygous for the condition.

After ingestion of L-cystine the plasma levels were somewhat lower in cystinuric than in normal subjects, but urinary cystine clearance was about 30 times higher. As before, methionine gave no clear-cut result. L-Cystine produced marked increases in plasma and urinary cystine in all subjects. The "incomplete cystinuria" showed a small rise in cystine output after taking a mixture of arginine, lysine and ornithine, but not after glycine.

In one cystinuric the renal clearances for cystine and inulin were almost identical. Fasting plasma cystine levels in 9 cystinuric subjects were 5.88 μ g. per ml., S.D. 1.5, against 10.64 μ g. per ml., S.D. 1.87 in 17 normal subjects.

It is concluded that cystinuria results from reduction or absence of tubular re-absorption of cystine.—D. Duncan.

labelled with ^{35}S .] *Biochem. Ztschr.*, 1954, **326**, 28-47. [Med. Klin., Univ. Cologne.]

A procedure is described for measuring the daily turnover of serum protein and other protein fractions. It avoids the sources of error inherent in the estimation of the breakdown rate of labelled serum proteins, and has the further advantage that the experiment lasts only a few hours. After intravenous injection of ^{35}S -methionine in trace doses, measurements are made at intervals of the specific activity of the free methionine in the serum, and the uptake of ^{35}S -methionine in the separate protein fractions. From these data the rate of turnover is calculated. The daily turnover of free serum methionine in the fasting rabbit was found to amount to 702 mg. Of this 5 mg. was taken up by the serum protein and 346 mg. by the rest of the body protein; 351 mg. was used in irreversible combination or broken down. The total amount of free methionine in the rabbit amounted to 13.8 mg. This amount was turned over once in about 29 min. Breakdown of body protein provided about 686 mg. free methionine daily.—M. B. Richards.

WU, C. and BOLLMAN, J. L. Effect of ethionine on the free amino acids in the rat. *J. Biol. Chem.*, 1954, **210**, 673-680. [Sect. Biochem., Mayo Clin., Rochester, Minn.]

Intraperitoneal injection of DL-ethionine caused increases in the concentration of free amino-acids in tissues, plasma and urine of rats, particularly plasma alanine, cystine, glutamine and serine, liver cystine, glutamine acid and methionine, and kidney cystine and serine. Taurine was considerably increased in the urine of males; glutamic acid, glutamine, glycine and serine, as well as taurine, were increased in the urine of females. Simultaneous injection of methionine decreased these effects.—C. Warner.

PHILLIPS, W. A., and BERG, C. P. Effect upon growth of the D isomers in synthetic mixtures of the essential amino acids. *J. Nutrition*, 1954, **53**, 481-498. [Biochem. Lab., State Univ. Iowa, Iowa City.]

The essential amino-acids, divided into 2 groups, (1) valine, leucine, isoleucine, lysine and threonine, which previous work had shown to be poorly utilised in the D-form, and (2) tryptophan, methionine, phenylalanine, histidine and arginine, with D-forms believed to be readily available for growth, were given to rats as sole source of N. When both groups of amino-acids were given in the L-form at suboptimum levels, addition of the D-form of group 1 amino-acids led to increased growth, presumably by providing N for synthesis of non-essential amino-acids; addition of small amounts of glycine and ammonium citrate supported much better growth; addition of the D-form of group 2 amino-acids had no marked effect; substitution of the D- for the L-form of group 2 amino-acids gave poor growth, presumably because of slow inversion. Lack of response to addition of the D-forms of group 2 amino-acids, known to be readily inverted when consumed singly, was thought to be due to saturation of the inverting system.—C. Warner.

SCOTT, E. B. Histopathology of amino-acid deficiencies. 3. Histidine. *Arch. Pathol.*, 1954, **58**, 129-141. [Dept. Anat., Sch. Med., Univ. S. Dakota, Vermillion.]

For previous parts see Absts. 5098, Vol. 21 and 3334, Vol. 24.

Three young rats were given to appetite a purified diet consisting of 19 crystalline amino-acids, vitamins, sucrose, cottonseed oil and salts; 12 similar rats were given to appetite the same diet without histidine, and 10 rats were pair-fed on the complete diet so that their food intake was equal to that of the deficient rats. After 42 days all, except 2 deficient rats, were killed and the adrenals, testes and pituitary were removed for examination. The 2 deficient rats were given the complete diet and were killed 45 days later.

The histidine-deficient rats showed the weight loss and poor appetite and appearance typical of protein deficiency, and their final weights were considerably less than those of the other 2 groups. Descriptions and illustrations are given of the changes in pituitary, testes, thymus, adrenals and bone, in all of which retrogression occurred. In the 2 deficient animals returned to the complete diet there was complete recovery.—G. F. Garton.

NiÑO-HERRERA, H., HARPER, A. E. and ELVEHJEM, C. A. Histological differentiation of fatty

livers produced by threonine or choline deficiency. *J. Nutrition*, 1954, **53**, 469-480. [Dept. Biochem., Coll. Agric., Univ. Wisconsin, Madison.]

Similar groups of 6 weanling rats were given food to appetite during experimental periods of 2 weeks. The basal diet consisted of sucrose 81.4, casein 9, maize oil 5, salts 4, methionine 0.3, tryptophan 0.1 and choline chloride 0.13 per cent., supplemented with vitamins A, D, E, K and those of the B group; alterations in the diet were made by substitution for an equal weight of sucrose. In choline-deficient diets methionine was replaced by cystine. After the experiment each rat was anaesthetised and liver samples were removed for histological examination and estimation of fat.

Fatty infiltration and, occasionally, necrosis were found in rats given the basal low-protein diet; these were not apparent when the diet contained additional protein, threonine or threonine and glycine. The structure of the livers of rats given diets in which the sucrose was replaced by either glucose or dextrin appeared normal. When choline was omitted from the basal diet fatty infiltration of the liver became even more marked.

Relation to creatine metabolism.] *Klin. Wochenschr.*, 1954, **32**, 815-817. [Med. Klin., Justus Liebig-Hochschule, Giessen.]

Before and after administration of 300 mg. cocarboxylase, partly intravenously and partly subcutaneously on a single day, creatine was estimated in the urine and pyruvic acid in the blood of 23 diabetics who usually excreted creatine in the urine. Creatine disappeared from the urine

of all the subjects for at least 2 days after treatment with cocarboxylase. The contents of creatinine in the urine and of pyruvic acid in the blood were not significantly affected. It is suggested that cocarboxylase relieves creatine phosphate of its phosphorylating function, so that creatine is no longer excreted.—E. M. Hume.

BROUWER, E. Opbouw en afbraak van vetten in het dierlijke organisme. [Synthesis and breakdown of fats in the animal organism.] *Chem. Weekblad*, 1954, **50**, No. 26, 449-455.

To Liebig, in 1842, is ascribed the view that fat can be built from carbohydrate by animals. Voit did not share this view, but it was vindicated

about the end of last century. The first 30 or 40 years of this century saw the development of Knoop's theory of β -oxidation and Krebs's tricarboxylic acid cycle, and it became evident that the pattern of intermediary metabolism is the same for plants, micro-organisms and animals. More recent techniques, with studies of tissue metabolism *in vitro* and of metabolism *in vivo* with isotopes, have established the breakdown of fat by 2-carbon stages, to give a "metabolic pool" of acetic acid or some related 2-carbon compound, and of carbohydrate to the same end product, via pyruvic acid. Synthesis up to C_{16} acids is by the reverse process and coenzyme A, a pantothenic acid derivative, is the link.—I. Leitch.

One man and 6 women, who were normal except for obesity of exogenous origin, were studied for 4 months. All received solid foods with fat- and protein-rich supplements; sufficient food was allowed to maintain weight throughout the study, which was divided into periods of several weeks when the dietary fat was almost entirely of animal or of vegetable origin.

In all the subjects serum free and esterified cholesterol and phospholipins fell abruptly when plant fat was substituted at the same energy level for animal fat, rose when animal fat was given and fell again when plant fat was given a second time.

POMERANZE, J., BEINFELD, W. H. and CHESSIN, M. **Serum lipid and fat tolerance studies in normal, obese and atherosclerotic subjects.** *Circulation*, 1954, **10**, 742-746. [Dept. Med., New York Med. Coll.] Spanish summary.

A fat tolerance test was made on 5 men with normal serum lipid values, 4 men with abnormal serum lipid values, 6 men over 70 years old with clinically established atherosclerosis, 10 moderately obese and 11 extremely obese subjects. For the test 204 g. fat was given in a test meal; blood samples were taken before the meal and at intervals during the next 24 hr. for estimation of total cholesterol, phospholipins and total fatty acids. All subjects except the obese were then given a diet containing less than 20 g. fat daily for up to 6 weeks and the fat tolerance test was repeated. The moderately obese subjects were given a 1000-Cal. diet containing at least 60 g. fat daily for 5 weeks, during which serial studies of serum cholesterol were made. The extremely obese individuals were given a diet providing 1200 to 1500 Cal. daily, including at least 60 g. fat, for up to 50 weeks; total serum cholesterol was estimated at regular intervals and fat tolerance tests were made before and after weight reduction.

Blood fat after the test meal rose and remained high in obese and atherosclerotic subjects and in those with abnormally high blood cholesterol

values. In the last and in those with atherosclerosis, restriction of fat resulted in marked improvement of fat tolerance; a similar improvement followed reduction in weight of extremely obese subjects.—G. A. Garton.

VAN ITALLIE, T. B., MOORE, F. D., GEYER, R. P. and STARE, F. J. **Will fat emulsions given intravenously promote protein synthesis? Metabolic studies on normal subjects and surgical patients.** *Surgery*, 1954, **36**, 720-731. [Dept. Nutrit., Harvard Sch. Pub. Health, Boston, Mass.]

Emulsions containing 15 per cent. lipid were administered intravenously to 2 healthy volunteers and to 2 patients who had undergone subtotal gastrectomy. The emulsions were composed of olive oil or coconut oil or equal parts of each 15 g., soya bean lecithin preparation 1 g., Demal-14 (emulsifying agent) 1 g. and glucose 4.3 g. per 100 ml. Metabolic effects were studied by analysis of the diets and of faeces and urine for N, K and Na; eosinophil counts were also made.

Both normal subjects were given a constant diet inadequate in energy and marginal with respect to protein intake. In one negative N and K balance diminished when fat was administered and increased when its administration ceased. In the other normal subject no effect of intravenous fat on N balance was observed, though cessation of intravenous fat injection was followed by a marked increase in K excretion.

The surgical patients were given enough intravenous fat for 6 days after the operation to maintain a daily intake of 1800 to 2000 Cal. The characteristic metabolic response to this type of surgical procedure was not measurably affected by the extra energy derived from fat. These patients may have been receiving less than their basal energy requirement, though they received more than is usual after major surgical operations.

RAMSEY, H. A., WISE, G. H., TOVE, S. B. and WAUGH, R. K. **Effects of various diets on the diurnal patterns of blood plasma lipides of dairy calves.** *J. Dairy Sci.*, 1954, **37**, 1357-1367. [Dept. Animal Indust., N. Carolina State Coll., Raleigh.]

Four calves were fed on 4 semi-synthetic milks composed of casein, minerals, vitamins, NaHCO₃ and butter or hydrogenated cottonseed oil with

lactose or glucose in a rotation of 2-week periods. Hourly samples of blood were taken for 12 hr. on the 7th and 14th day of each period.

The diurnal patterns of total lipids, lipid P and total cholesterol were similar in all. "Plasma fat", measured by Allen's method, which approximates to the sum of neutral fat, free cholesterol and cholesterol esters (Abst. 1332, Vol. 21), showed different diurnal patterns. In calves given butterfat, "plasma fat" began to fall immediately; after hydrogenated cottonseed oil it rose to a peak after 2 hr., then fell below the initial level. Both patterns were similar to those of total lipids after 5 hr. Blood sugar from calves fed on glucose rose more rapidly to a higher peak, declined more precipitously and equilibrated more slowly than when the diet contained lactose. Neither carbohydrate affected the "plasma fat", nor did the type of fat influence the blood sugar.

In a similar experiment the effect of 2 diets, one containing cottonseed oil and lactose and the other containing non-fat milk solids instead of casein, lactose, vitamins and the mineral mixture, were studied. In 4 calves, after the diet containing non-fat milk solids, "plasma fat" increased during the first 3 hr., dropped slightly, then increased to the 7th hr. With the other diet "plasma fat" fell for 4 hr., then rose to a peak at the 8th hr., after which both patterns were the same. From the 2 experiments it was evident that "plasma fat" reflected not only the nature of the dietary fat but also other influences, which are discussed.—A. Hepburn.

PERETTI, G. and LIGUORI, G. L'assorbimento dei lipidi durante il digiuno proteico. [Absorption of lipids during protein deprivation.] *Arch. Sci. biol., Bologna*, 1954, **38**, 481-492. [Ist. Fisiol. Umana, Univ. Cagliari.]

Three groups, of 10, 4 and 10 rats, received initially 3 diets containing 8 to 9.56 per cent. casein and 3 to 4.3 per cent. ovalbumin, with 2, 10 and 20 per cent. olive oil. Each diet provided 35.2 Cal. per g. protein. The rats were kept in individual metabolism cages for quantitative collection of faeces and urine. After 9 days on these diets they received similar diets with the protein replaced by starch, until N excretion stabilised at a low level. They were then re-fed on the original diets until they again reached N equilibrium. Fat balances were studied. At the end of each phase some rats of each group were starved for 12 hr., given olive oil by stomach tube and killed 6 hr. later for estimation of the amount remaining in the stomach and intestine.

The results for 2 rats on different diets are presented in full, and mean fat balances for each rat in each period are tabulated for the rest. Fat

absorption was slightly reduced after protein depletion, as shown both by the balance studies and by the uptake of olive oil from the digestive tract. On protein repletion the fat uptake rose above the control level.—D. Duncan.

BURK, W. W. (JR.), DUNKELBERG, C., MCPHERSON, J. C. and TIDWELL, H. C. Blood levels of absorbed labeled fat and chylomicronemia. *J. Biol. Chem.*, 1954, **210**, 531-537. [Dept. Biochem., Southwestern Med. Sch. Univ. Texas, Dallas.]

Rats were given water and glucose to appetite for 48 hr. and then by stomach tube 0.3 ml. lipid, 1.3 per cent. palmitic acid-1-¹⁴C in olive oil, per sq. dm. body surface. Blood samples were taken hourly for radio-activity studies or chylomicron counts. Two and 4 hr. after the labelled acid was given, animals were anaesthetised and blood was obtained by heart puncture.

More than 90 per cent. of the total radio-activity of blood was in the lipid fraction. The radio-activity of blood lipids was proportional to the chylomicron counts, confirming the observation of Moreton (Abst. 3792, Vol. 20) that the increase in chylomicrons during alimentary lipaemia is due to active uptake of fat.—G. A. Garton.

2273

SWANK, R. L. Effect of high fat feedings on viscosity of the blood. *Science*, 1954, **120**, 427-428. [Div. Neurol., Dept. Med. Sch., Univ. Oregon, Portland.]

Hamsters fed on a diet in which about half the energy came from butterfat for 5 to 7 days were then given a single fat meal of 2 to 3 ml. of 35 per cent. cream. The animals were anaesthetised and their blood viscosities and haematocrits were studied 3, 6, 9, 14, 24, 48 and 72 hr. after the meal of cream.

The blood viscosity increased after about 3 hr. and continued to increase to a maximum at 6 to 9 hr., followed by a decline to normal by the end of 24 hr. During the first 9 hr. minor variations in the haematocrit were noted; this was followed by a significant fall and then a return to normal in between 24 and 72 hr.

Gross inspection of the viscera of the animals with increased blood viscosity revealed an unusual degree of cyanosis of the venous blood, hyperaemia, engorged arteries in the stomach and omentum and a reduced tendency to bleed from the vena cava when puncture wounds were made for blood sampling.—G. A. Garton.

HOLASEK, A. Über den Ursprung des Kofettes. 1. Untersuchungen an fettfrei ernährten

N.A. and R., April 1955

Ratten. [Origin of faecal fat. 1. Experiments with rats on a fat-free diet.] *Hoppe-Seyler's Ztschr.*, 1954, 298, 55-64. [Med. Chem. Inst., Univ. Graz.]

Fat in faeces was estimated: the faeces were extracted with hot acid alcohol, then repeatedly with ether. The ether was evaporated. The residue was dissolved in alcohol, saponified with NaOH and extracted with light petroleum: after evaporation of the solvent the residue was dissolved in 86 per cent. ethanol and the higher fatty acids were precipitated with urea and titrated with 0.1 N NaOH.

The results are presented in terms of dry weight of faeces, NaOH for the final titration in ml. and m. equiv. fatty acids for 10 rats. The diet was of separated milk, with 0.03 per cent. lipid as a maximum, sugar, extracted starch or bread and, in 3 of the 5 experiments, cellulose. In the experiments with cellulose, the dry weight of faeces per 10 rats was 18 to 21, 27 to 50 (unrestricted food for part of the time) and 22 to 30 g. daily. Corresponding fatty acid, m. equiv. per 10 rats, was 0.34 to 0.42, 0.44 rising to 0.47 with increase of food and falling to 0.25, and 0.47 falling to 0.03 on the third of 4 days when terramycin was given.

In the first of the 2 experiments without cellulose, with a diet of bread and milk, the dry weight of faeces was from 7.3 to 8.9 g. and m. equiv. fatty acids from 0.76 to 0.89 per 10 rats daily. When aureomycin was given with this diet, faeces became so soft they could not be collected completely and there was coprophagy. The fall of fatty acids to 0.24 m. equiv. is in part attributed to coprophagy and in part to the aureomycin.

The conclusions drawn are that the fat in faeces of rats on diets almost free from fat is bacterial fat and that the smaller total amount of fat when the diet contains cellulose is due to the faster passage of food through the gastro-intestinal tract. [No marker seems to have been used and no estimate was made of cellulose in faeces.]

HOCK, A., HUBER, G., PILCHAU, A. P. v. and SANDERSLEBEN, J. v. Chemische und morphologische Veränderungen im Lebergewebe von Ratten unter ernährungsbedingten Leberschädigungen. [Chemical and morphological changes in the liver of rats with dietary liver damage.] *Arch. Tierernährung*, 1954, 4, No. 4, Beihefte, 256-270. [Zellstoff Fabrik Waldhof, Giessen.]

Albino Wistar-type rats were fed on a diet of defatted casein 16, lard treated with ferric chloride to destroy tocopherol 51, maize starch 30 and McCollum salt mixture 3 per cent., with per kg. of the mixture, vitamin B₁ 2, riboflavin 2.5, pyri-

doxine 2, Ca pantothenate 10, nicotinamide 25, *p*-aminobenzoic acid 25, inositol 25 and biotin 0.2 mg.; and 500 I.U. of vitamins A and D. The diet was almost free from choline, tocopherol, vitamin B₁₂ and folic acid. The casein contained 1.56 per cent. methionine which, at 10 g. of the mixture daily, gave 25 mg. methionine, enough for all normal needs. The average initial weight was about 130 g. and rats were killed at intervals up to 230 days on experiment. In liver, total lipids, phospholipins, protein and nucleic acid were estimated. The results are presented in tables, a graph and photomicrographs.

Liver fat rose to 60 per cent. of dry matter and was deposited mostly in the centre of the lobules. Towards the end of the experiment, in survivors, small foci of necrosis appeared but there was little nuclear change and no fibrosis. Phospholipins, protein and nucleic acids were greatly reduced in relation to liver weight for a time but were normal again by the end of the experiment. About a tenth of the rats died after 160 days of acute necrosis.—I. Leitch.

NIEMAN, C., GROOT, E. H. and JANSEN, B. C. P. The nutritive value of butter fat compared with that of vegetable fats. 1. Biological experiments. *Proc. Kon. Ned. Akad. v. Wetensch. Amsterdam Ser. C*, 1952, 55, 587-604. [Netherlands Inst. Nat. Nutrit., Amsterdam.]

A survey is made of the results of a large number of growth experiments with rats to compare the nutritive value of arachis oil plus vitamins A and D with butter. The growth figures obtained in the older, similar experiments of Boer and Jansen (*Arch. néerl. Physiol.*, 1942, 26, 1) were also investigated statistically.

It is concluded that butterfat has a greater nutritive value than arachis oil, even when the latter is supplemented with β -carotene and calciferol or with the unsaponifiable matter of butterfat.

Part 2, Statistical Analyses, has been published by C. van Eeden (Report S 63 of the Statistical Department of the Mathematical Centre at Amsterdam), *Proc. Kon. Ned. Akad. v. Wetensch., Amsterdam Ser. C*, 1952, 55, 605-616, and is obtainable on request.—G. A. Garton.

DEUEL, H. J. (Jr.), MARTIN, C. R. and ALFIN-SLATER, R. B. The effect of fat level of the diet on general nutrition. 12. The requirement of essential fatty acids for pregnancy and lactation. *J. Nutrition*, 1954, 54, 193-199. [Dept. Biochem. Nutrit., Sch. Med., Univ. S. California, Los Angeles.]

See also Abst. 4821, Vol. 24.

Female weanling rats were given a fat-free diet for 10 weeks. They were then divided into 2 series of groups which received supplements of cottonseed oil or linoleate with a control group for each series, and were mated with proven stock males. In the first series most of the groups contained 25 females and the daily supplements of cottonseed oil given to the 6 groups ranged from 10 to 1000 mg. In the second series there were 16 animals to a group and the daily supplements of linoleate given to the 6 groups ranged from 2.5 to 80 mg.

In the control group of the first series 83 per cent. of females had litters of average size 6.4 at birth, compared with 92 to 100 per cent. litters of average size 8.3 to 9.9 in the supplemented groups. During the first 3 days of life mortality in the control young was 100 per cent. The level of cottonseed oil required for optimum lactation, as judged from percentage survival and average bodyweight of young at 21 days, was between 100 and 200 mg. daily, which was considered to be equivalent to between 50 and 100 mg. linoleate. In the second series 87 per cent. of control females had litters of average size 4.9 at birth, compared with 87 to 100 per cent. and average size 6.6 to 7.5 in the supplemented groups. None of the young in the control group or in the groups receiving 2.5 and 5.0 mg. linoleate daily survived 3 days. The group which received 80 mg. linoleate daily yielded lactation results comparable with the optimum recorded for cottonseed oil.—F. C. Aitken.

CHENG, A. L. S., ALFEN-SLATER, R. B. and DEUEL, H. J. (Jr.) The effect of fat level of the diet on general nutrition. 13. The effect of increasing dosages of x-irradiation on the protective action of fat on radiation injury. *J. Nutrition*, 1954, 54, 201-207. [Dept. Biochem. Nutrit., Sch. Med., Univ. S. California, Los Angeles.]

Male rats were given at weaning one of 3 test diets. These were 2 low-fat diets containing 20 per cent. vitamin-test casein or 20 per cent. commercial casein and one containing 24 per cent. commercial casein and 15 per cent. cottonseed oil. The test diets were given for 3, 5, or 8 weeks before animals were exposed to X-rays. The levels of irradiation were 300 r weekly for 1 to 5 weeks; 400 r weekly for 1 to 3 weeks; 500 r weekly for 1 or 2 weeks. In all 33 tests were made. With a few exceptions rats given the diet containing fat survived better than rats on the low-fat diets and rats on the low-fat diet containing commercial casein survived better than those on the diet containing purified casein. Three weeks of the fat diet sufficed for its protective effect to be shown.

ERSHOFF, B. H. Beneficial effect of low-fat diets on the swimming performance of rats and mice in cold water. *J. Nutrition*, 1954, 53, 439-449. [Dept. Biochem. Nutrit., Univ. S. California, Los Angeles.]

The swimming performance of young mice was studied at 20° and 37° C., that of adult mice at 20° C. and of rats at 20° and 37° C. At 20° C. all animals which had received a fat-free diet or a similar diet supplemented with 1 per cent. cottonseed oil or 1 per cent. hydrogenated cottonseed oil swam for a significantly longer time than did animals given a similar diet supplemented with 10 per cent. cottonseed oil or 10 per cent. hydrogenated cottonseed oil. When the fat-free diet was supplemented with 2.5 per cent. of oil, adult mice swam for a time intermediate between that swum by those on the fat-free and 10 per cent. fat diets. The protective effects of the fat-free diets were evident within 3 days of administration. In the swimming tests at 37° C. there was no significant difference in performance due to diet.

FAWCETT, D. W. and LYMAN, C. P. The effect of low environmental temperature on the composition of depot fat in relation to hibernation. *J. Physiol.*, 1954, 126, 235-247. [Dept. Anat., Harvard Med. Sch., Boston, Mass.]

Groups of hamsters were given, for 6 to 12 weeks, 3 diets: (1) Purina chow, (2) chow plus 20 per cent. peanut oil (iodine value 93) and (3) chow plus 20 per cent. beef tallow (iodine value 45). Half the animals in each group were kept in an environmental temperature of 20° to 25° C. and half in a cold room at 5° ± 2° C. in individual cages with suitable bedding. Of 2 groups of rats treated similarly, one group received chow and the other diet 3. Fat was obtained from subcutaneous tissue and abdominal depots for estimation of the I value.

The fat of hamsters, which hibernate, when they were maintained on stock diet at room temperature had an I value of 83.7, compared with 87.3 for animals on the same diet at 5° C. The corresponding I values of the fats of the hamsters given peanut oil or tallow were 87.4 and 92.1, and 71.5 and 77.7. It was concluded that a low environmental temperature occasions a significant decrease in saturation of depot fats, the extent of which is about the same whatever the pre-existing level of saturation determined by the dietary fat. No such change was found in the depot fats of the rats. No effect of cold on the I value of the fat of ground-squirrels (*Citellus tridecemlineatus*) was found, since they entered into hibernation so

quickly that there was not enough time for replacement of their depot fat (I value 93.5 on chow diet with fat synthesised in the cold environment.

TOVE, S. B., SMITH, F. H., YOUNG, C. T. and SHERWOOD, F. W. **Effect of source of dietary protein on the unsaturated fatty acids in the carcass fat of the rat.** *J. Nutrition*, 1954, **54**, 49-57. [Animal Nutrit. Sect., Dept. Animal Indust., N. Carolina Agric. Exp. Stat., Raleigh.]

Groups of weanling male rats were fed to appetite for 6 or 7 weeks on 17 diets, details of which are given in a table; several of the diets contained a high proportion of ether-extracted cottonseed meal or soya bean meal. The animals were then killed and their carcass fat was extracted and analysed for unsaturated fatty acids by alkali-isomerisation and spectrophotometric examination.

It was concluded that the unsaturated fatty acid composition of the dietary fat exerted a major influence on the unsaturated fatty acid composition of the depot fats. The results suggest that soya bean meal and cottonseed meal contain one or more substances which can affect the metabolism of unsaturated fatty acids, since these meals, although ether-extracted, increased the content of diethenoid acids and decreased that of monoethenoid acids in the carcass fats.

BERGSTRÖM, S., BLOMSTRAND, R. and BORGSTRÖM, B. **Route of absorption of distribution of oleic acid and triolein in the rat.** *Biochem. J.*, 1954, **58**, 600-604. [Dept. Physiol. Chem., Univ. Lund, Sweden.]

Male rats, some with thoracic duct fistulae, were given oleic acid or triolein labelled with ^{14}C by stomach tube. The lipids of lymph subsequently collected were fractionated into neutral fat and phospholipins on silicic acid columns for estimation of the radio-activity of their constituent fatty acids. The fatty acids of the lipids of the intestinal wall were also examined and the amount of radio-activity in the respired CO_2 was measured.

When labelled oleic acid was given, 66 to 92 per cent. of the activity was absorbed in 24 hr.; the figures for triolein were 57 to 92 per cent. The activity recovered from the lymph lipids,

mainly in the neutral fat, was 38 to 96 per cent. of that absorbed from the free acid and 51 to 83 per cent. of that from the triglyceride; only about 2 per cent. of the activity was in phospholipins.

The considerable variation in the results between different animals is discussed, and it is suggested that those rats on which the highest recoveries of radio-activity were made were those most approaching the normal physiological state. It is concluded that there is no detectable difference between the pathways of absorption from the intestine of oleic acid and triolein.—G. A. Garton.

BERGSTRÖM, S., BORGSTRÖM, B., TRYDING, N. and WESTRÖÖ, G. **Intestinal absorption and metabolism of 2:2-dimethylstearic acid in the rat.** *Biochem. J.*, 1954, **58**, 604-608. [Dept. Physiol. Chem., Univ. Lund, Sweden.]

Adult male rats, housed in metabolism cages, were fed to appetite on a diet of white bread and water and given by stomach tube 2:2-dimethyl-[1- ^{14}C]-stearic acid dissolved in olive oil. Respiratory CO_2 , faeces and urine were collected for measurement of radio-activity and identification of urinary metabolic products. In another experiment a rat with a cannula in the thoracic duct was similarly given the labelled acid and lymph was collected for 24 hr. The lymph fat was examined by chromatography on silicic acid and Amberlite columns.

The labelled acid was well absorbed and more than 90 per cent. of the radio-activity absorbed was accounted for as [^{14}C]-dimethyl-adipic acid in the urine; no radio-activity was detected in the respired CO_2 . The acid was present in lymph glycerides and phospholipins. Experiments *in vivo*, in which the labelled glyceride fraction of lymph lipids was incubated with pancreatic juice and bile, showed that the glyceryl ester bond was resistant to the action of lipase.—G. A. Garton.

REINIUS, L. and TURPEINEN, O. **Biosynthesis of ^{14}C -labeled linoleic acid and its fate in normal and fat-deficient rats.** *Acta chem. scand.*, 1954, **8**, 1001-1006. [Dept. Physiol. Biochem., Vet. Coll., Helsinki.]

Linoleic acid labelled with ^{14}C was prepared by culturing the yeast-like organism *Trichosporon pullulans* in a medium containing ^{14}C -labelled sugars. Fatty acids were isolated from the mycelium and the radio-active linoleic acid was prepared as ethyl ester by the bromination-debromination procedure. The ester was given to 2 female rats, one of which had been maintained on a stock diet and the other on a fat-deficient regimen. Six hr. later the animals were killed and lipids were extracted from liver, kidneys,

heart, brain, subcutaneous tissue, perirenal adipose tissue, mesentery and omentum, genital adipose tissue and gastro-intestinal tract, and from faeces, for estimation of their radio-activity.

In the fat-deficient rat the intestinal absorption of linoleate was more rapid and a proportionally greater part of the absorbed activity was found in liver, kidney and heart lipids than in the similarly treated animal fed on the stock diet. In the latter rat the subcutaneous adipose tissue contained relatively more of the absorbed ^{14}C .

HOLMAN, R. T. and ENER, S. Use of urea-inclusion compound containing essential fatty acid in an experimental diet. *J. Nutrition*, 1954, **53**, 461-468. [Hormel Inst., Univ. Minnesota, Austin.]

Four groups of 4-month-old rats which had been fed from weaning on a basal fat-free diet were then fed for several months on the basal diet plus, per kg. diet, (1) 80 g. urea-inclusion compound of the ethyl esters of the fatty acids of maize oil, or (2) 20 g. maize oil, or (3) 60 g. urea; the control group continued to receive the fat-free diet. The rats were inspected periodically for signs of deficiency of essential fatty acids. At the end of the experiment total carcass fat was analysed for arachidonic acid.

The changes in the skin and in arachidonic acid content of the carcass fat indicated that the essential fatty acid esters were equally active in the free state or as urea-inclusion compounds. The animals with urea in the diet suffered no injury, though the diuretic effect was reflected in increased water intake.

It is not recommended that urea-inclusion compounds should be used generally for the incorporation of fats in experimental diets, except when supplementation with unsaturated fatty acids or esters is an essential part of an experimental procedure; the acids or esters would then be protected from oxidation and could be incorporated directly into the diet instead of being given separately as has been common practice.

REID, M. E. Production and counteraction of a fatty acid deficiency in the guinea pig. *Proc. Soc. Exp. Biol. Med.*, 1954, **86**, 708-709. [Lab. Biochem. Nutrit., Nat. Inst. Health, Bethesda, Md.]

In 3 groups, each of 8 male and 8 female guinea-pigs, half the animals received the diet previously described (Abst. 3515, Vol. 24), the others a similar diet with fat replaced by cerelose.

After 6 to 8 weeks the guinea-pigs on the fat-free diet showed retardation of growth, dermatitis,

drying of the inside of the ears, and, in some, ulcers, loss of fur and swollen cyanotic feet. All these signs were abolished by administration of maize oil or linoleic acid by mouth, which showed that this acid or other fatty acids present in maize oil are essential in the diet of the guinea-pig.

ALFEN-SLATER, R. B., AFTERGOOD, L., WELLS, A. F. and DEUEL, H. J. (Jr.) The effect of essential fatty acid deficiency on the distribution of endogenous cholesterol in the plasma and liver of the rat. *Arch. Biochem. Biophys.*, 1954, **52**, 180-185. [Dept. Biochem. Nutrit., Sch. Med., Univ. S. California, Los Angeles.]

Adult rats were fed for 20 weeks on a low-fat diet to deplete them of essential fatty acids. Blood was then obtained by heart puncture and the livers were removed. Plasma lipids were studied after extraction with ethanol and acetone and liver lipids after extraction with light petroleum; in some the lipids of the adrenals were estimated after ethanol and ether extraction. All extracts were analysed for cholesterol by the method of Nefit and Deuel (Abst. 599, Vol. 19).

The cholesterol content of the liver and adrenals was higher and that of the plasma lower in animals which had received the low-fat diet than in controls which received a diet containing 12.5 per cent. cottonseed oil. The extra liver cholesterol was almost entirely in the ester form.

It is suggested that, in deficiency of essential fatty acids, cholesterol esters containing fatty acids other than polyunsaturated acids may be formed and be unavailable for normal metabolism.

MAYER, G. A., CONNELL, W. F., DEWOLFE, M. S. and BEVERIDGE, J. M. R. Diet and plasma cholesterol levels. *Amer. J. Clin. Nutrit.*, 1954, **2**, 316-322. [Dept. Med., Fac. Med., Queen's Univ., Kingston, Ont.] Spanish summary.

Five healthy men who had been in nutritional balance for 3 to 4 months received for 4 weeks a diet which supplied 100 to 180 mg. cholesterol

N.A. and R., April 1955

daily, and 10.9 to 18.9 per cent. of the total energy in the form of fat. For the next week they received a diet which supplied 900 to 980 mg. cholesterol daily with the same proportion of fat as in the first diet. For the sixth week the subjects received a diet which supplied 100 to 180 mg. cholesterol daily and 34 to 46 per cent. of the total energy as vegetable fat; during the last 2 weeks of experiment they received a diet which supplied 210 to 300 mg. cholesterol daily and 34 to 46 per cent. of the total energy as animal fat. The intakes of cholesterol and animal and vegetable fat were closely controlled, but carbohydrate foods such as potatoes, sugar, marmalade, bread and arrowroot biscuits were allowed to appetite in order to maintain bodyweight. Blood samples were taken before breakfast at intervals throughout the experiment, and total and free cholesterol were estimated in the plasma.

The diet low in fat and cholesterol produced a highly significant fall in plasma cholesterol; the addition of cholesterol in the form of egg yolk to the diet did not produce any change in plasma cholesterol. When the intake of vegetable fat was increased a significant rise occurred in plasma cholesterol; it remained high, but was not increased further, on substitution of animal for vegetable fat and consequent increase of cholesterol intake.—G. F. Garton.

WALKER, A. R. P. and ARVIDSSON, U. B. Fat intake, serum cholesterol concentration and atherosclerosis in the South African Bantu. 1. Low fat intake and the age trend of serum cholesterol concentration in the South African Bantu.

HIGGINSON, J. and PEPLER, W. J. 2. Atherosclerosis and coronary artery disease. *J. Clin. Invest.*, 1954, 33, 1358-1365; 1366-1371. [Human Biochem. Unit, S. African Inst. Med. Res., Johannesburg.]

1. The fat in the diet of Bantu in Southern Africa who are consuming their customary foods appears, from dietary studies, to provide less than 20 per cent. of their energy intake.

Preliminary to a comparative study the effects of ageing on the level of cholesterol in the blood serum of Bantu were studied. Two hundred and eighteen subjects, 167 men and 51 women between 15 and 93 years of age, were chosen from hospital patients with diseases unlikely to affect either

their nutritional state or the level of cholesterol in their blood. The findings were compared with those of Keys *et al.* (Abst. 5242, Vol. 20) for Minnesota inhabitants. Below 40 years the means for 10-year age groups did not differ, but after that age those for Bantu were significantly lower than those for Americans.

Five racial groups were investigated, one of which was subdivided into 2 age groups. Descriptions of these groups, the number of subjects and distributions of ages and levels of cholesterol per 100 ml. serum were as follows: (1) Johannesburg Bantu, 85 between 21 and 40, mean 31 years, 88 to 265 mg., mean 167 ± 33 mg.; (2) Bechuanas, 38 between 21 and 38, mean 30 years, 86 to 210 mg., mean 149 ± 36 mg.; (3) Basutos, 31 between 21 and 40, mean 29 years, 94 to 221 mg., mean 153 ± 37 mg.; (4) Europeanised Bantu, 69 between 21 and 40, mean 31 years, 100 to 249 mg., mean 178 ± 36 mg.; (5) South African Europeans, 55 between 21 and 30, mean 28 years, 145 to 322 mg., mean 206 ± 35 mg. and 46 between 41 and 50, mean 46 years, 186 to 328 mg., mean 238 ± 38 mg. The level for group 4 was significantly higher than the levels for groups 2 and 3 but not so in comparison with that for group 1.

This result and consideration of the findings of Groen *et al.* (Title 1803, Vol. 23) and of Donath *et al.* (Abst. 4919, Vol. 23) suggested that the low fat content of the diet of rural Bantu may not solely have been responsible for the low serum cholesterol levels; the high fibre content may also have played a part.

2. In post-mortem examinations of Bantu subjects, 300 men and 223 women, cardiovascular disease was established as the cause of death of 84 men and 66 women. From information available on the condition of the aorta and coronary vessels such comparisons as were possible were made with the data of Wanscher *et al.* (*Brit. J. Cancer*, 1951, 5, 172) for Danes, and those of Clawson (*Amer. Heart J.*, 1939, 17, 387) for Americans. The incidence of atherosclerosis among Bantu was concluded to be lower than in the white populations. These results in association with those in Part 1 support the view that a population with a low serum cholesterol level tends to have a low incidence of severe atherosclerosis.—D. Harvey.

HOLMAN, R. L. Cholesterol in the pathogenesis of arterial lesions. *Southern Med. J.*, 1954, 47, 537-543 (with discussion 543-544). Dept. Pathol., Sch. Med., Louisiana State Univ., New Orleans.]

The author distinguishes as arteriosclerosis changes in the walls of the arteries that are due to

age, and as atherosclerosis those of metabolic origin.

Arterial lesions resembling rheumatic arteritis and *periarteritis nodosa* were produced in 90 per cent. of dogs when they were fed on a high fat diet for 8 weeks or longer, after which renal insufficiency was produced by removal of both kidneys or subcutaneous injection of a heavy metal such as uranium nitrate. Search revealed no evidence of disturbance in lipid metabolism. Contrary to expectation, cholesterol, added to the diet before or during the induction of renal insufficiency, prevented the arterial lesions instead of modifying or increasing them.

A preliminary report is made on the state of the aorta in 96 human subjects aged from 1 to 17 years with juvenile atherosclerosis. Staining with Sudan IV showed focal deposits of lipid material on the intimal surface of the aorta in all but 7, and in all of those beyond the age of 3 years.

Fatty acid in some form is considered more likely to be culpable than cholesterol.

E. M. Hume.

COOK, R. P., KLIMAN, A. and FIESER, L. F. The absorption and metabolism of cholesterol and its main companions in the rabbit. With observations on the atherogenic nature of the sterols. *Arch. Biochem. Biophys.*, 1954, 52, 439-450. [Converse Mem. Lab., Harvard Univ., Cambridge, Mass.]

Rabbits 3 to 6 months old and weighing 2 to 3 kg. were fed for 23 to 25 days on diets containing 16.6 per cent. olive oil and 1 per cent. cholesterol, lathosterol (Δ^7 -cholesterol), 7-dehydrocholesterol or cholestanol. Faeces were collected daily and the sterols were extracted for estimation of "apparent" absorption. Blood sterols were estimated after 10 days and again at the end of the experiment. At post mortem the aortas were examined for atheromatous lesions and portions of liver and brain tissue were taken for histological examination and analysis for sterols; sterols were also estimated in the lipids of the carcass.

The unsaturated sterols were absorbed to the extent of about 90 per cent., corresponding to 0.25 g. per kg. bodyweight daily; the absorption of cholestanol was about 0.2 g. per kg. bodyweight daily. The concentration of sterol in serum and livers was much higher than in control animals; interconversion of unsaturated sterols occurred and it was established that Δ^5 -cholestenol (cholesterol) was the main sterol present in the equilibrium mixture. After the administration of cholestanol the percentage of this sterol found in serum, liver and carcass was much greater than with any of the other sterols, indicating storage. All the sterols gave rise to atheromatous lesions of the aorta.—G. A. Garton.

BYERS, S. O. and FRIEDMAN, M. (with GUNNING, B., OMOTO, C. and HAYASHI, W.) Observations concerning the production and excretion of cholesterol in mammals. 13. Role of chylomicra in transport of cholesterol and lipid. *Amer. J. Physiol.*, 1954, 179, 79-84. [Harold Brunn Inst., Mount Zion Hosp., San Francisco, Calif.]

The distribution of cholesterol and lipid was studied in the upper (chylomicron) and lower layers of centrifuged intestinal lymph and plasma from groups of male rats given excess of dietary cholesterol. Similar studies were made on the plasma of animals with high blood lipids and cholesterol occasioned by a diet supplemented with cholesterol and cholic acid, by the injection of rabbit anti-kidney serum or by biliary obstruction.

Absorbed dietary cholesterol was found almost exclusively in particulate (chylomicron) form in the lymph and a considerable proportion was found in particulate form in the plasma. Cholesterol produced endogenously in the normal rat was dissolved in the plasma, but in nephrotic animals (those injected with anti-kidney serum) some was in chylomicrons.—G. A. Garton.

RICE, L. I., SCHOTZ, M. C., POWELL, J. R. and ALFEN-SLATER, R. B. Effect of reticulo-endothelial blocking agents on plasma and liver cholesterol levels in the rat. *Amer. J. Physiol.*, 1954, 178, 483-485. [Dept. Biochem. Nutrit., Univ. S. California, Los Angeles.]

Groups of rats were fed on either a low-cholesterol diet or one containing 1 per cent. cholesterol and 0.5 per cent. sodium glycocholate, and were given repeated intravenous injections of saline or a mixture of 1 vol. of 4 per cent. Trypan Red in 0.85 per cent. saline and 2 vol. Thorotrast, a stabilised suspension of thorium dioxide. Blood was taken by heart puncture and plasma lipids were extracted for estimation of free and total

cholesterol; liver lipids were similarly examined and samples of liver tissue were studied histologically for fatty infiltration and blocking of Kupffer cells.

Treatment with Trypan Red and Thorotrast prevented the increased deposition of liver cholesterol normally found in rats fed on cholesterol; no effect was noted on the liver cholesterol of animals on the low-cholesterol diet. After injection of the blocking agents plasma cholesterol was less in animals on high-cholesterol or low-cholesterol diets than in animals on similar diets given saline injections.

The role of the reticulo-endothelial system in cholesterol metabolism is discussed.

G. A. Garton.

ALFEN-SLATER, R. B., WELLS, A. F., AFTERGOOD, L., MELNICK, D. and DEUEL, H. J. (Jr.) The effect of plant sterols on cholesterol levels in the rat. *Circulation Res.*, 1954, 2, 471-475. [Dept. Biochem. Nutrit., Sch. Med., Univ. S. California, Los Angeles.]

Weanling rats were fed for 6 weeks on diets containing either 1 per cent. cholesterol, 3 per cent. soya bean sterols (sitosterol and stigmasterols) or a combination of these. At the end of the experiment blood was obtained by heart puncture. Lipids were extracted from plasma, liver and carcase for estimation of free and total cholesterol.

Lower plasma cholesterol levels were not found when soya bean sterols and cholesterol were both included in the diet; no significant difference was noted in carcase cholesterol or carcase total lipid values. The cholesterol and total lipid contents of the livers of animals given both soya bean sterols and cholesterol were much less than in livers of rats which received cholesterol only.

BURKE, K. A., McCANDLESS, R. F. J. and KRITCHEVSKY, D. Effect of soybean sterols on liver deposition of cholesterol- C^{14} . *Proc. Soc. Exp. Biol. Med.*, 1954, 87, 87-88. [Div. Nutrit., Lederle Labs. Div., American Cyanamid Co., Pearl River, N.Y.]

Three groups each of 4 rats were used. The animals in groups 1 and 2 were fed for 120 days on rat chow supplemented with 3 per cent. cholesterol dissolved in 4 per cent. maize oil, and group 3 was given rat chow with 3 per cent. cholesterol and 5 per cent. mixed soya bean sterols for the same periods. Each rat was then given, by stomach tube, 10 mg. randomly-labelled C^{14} -cholesterol dissolved in 1 ml. maize oil; in group 2 the labelled sterol was followed immediately by 1 g. mixed soya bean sterols. Faeces and urine were collected from each animal for 4 days and pooled for C^{14}

assay; the rats were then killed and the livers were analysed for C^{14} activity in the cholesterol (unsaponifiable) and acidic fractions.

The average recovery of labelled cholesterol from the livers was 6.61 per cent. in group 1, 1.80 per cent. in group 2 and 0.47 per cent. in group 3; the average recoveries of C^{14} in the unsaponifiable matter of faeces were 20.14, 25.13 and 27.76 per cent.—G. A. Garton.

PETERSON, D. W., SHNEOUR, E. A. and PEEK, N. F.

Effects of dietary sterols and sterol esters on plasma and liver cholesterol in the chick. *J. Nutrition*, 1954, 53, 451-459. [Dept. Poultry Husb., Coll. Agric., Univ. California, Berkeley.]

Male chicks were fed on a stock diet until they were 3 weeks old and were then transferred to diets containing 4 per cent. cottonseed oil and cholesteryl acetate, caprate, myristate, palmitate, stearate or oleate; each ester was incorporated in the diet at a level equivalent to 1 per cent. of cholesterol. Total plasma cholesterol was estimated weekly for 4 weeks, after which the animals were killed and liver cholesterol was estimated.

Cholesteryl esters produced lower plasma and liver cholesterol levels than did free cholesterol. Cholesteryl, ergosteryl and dihydrocholesteryl palmitates, when given together with cholesterol, did not prevent the increases in tissue cholesterol which occurred with the free sterols alone.

In similar experiments cholic acid, oleic acid or cottonseed oil given with cholesterol enhanced increases in plasma cholesterol values; these increases were prevented by the addition of mixed soya bean sterols to the diet.

RIDOUT, J. H., LUCAS, C. C., PATTERSON, J. M. and BEST, C. H. Changes in chemical composition during the development of 'cholesterol fatty livers'. *Biochem. J.*, 1954, 58, 297-301. [Banting and Best Dept. Med. Res., Univ. Toronto.]

Groups of rats were fed on hypolipotropic diets without or with 0.2, 0.5, 0.8 or 1.6 per cent. crystalline cholesterol. Animals were killed after 3, 7, 14, 21, 35 and 49 days and the liver lipids were extracted and analysed as already described (Abst. 4235, Vol. 16).

During the first 3 weeks the increased weight of the livers was mainly accounted for by increased incorporation of glycerides and water. After this the nature of the deposited materials changed; the amount of glycerides decreased and the water content increased, though the sum of the 2 accounted for about 80 per cent. of the gain in liver

weight. The percentage of total liver lipids reached a limit in about 3 weeks, though the absolute amount of glycerides and cholesterol esters continued to increase.—G. A. Garton.

2302

RIDOUT, J. H., LUCAS, C. C., PATTERSON, J. M. and BEST, C. H. **Preventive and curative studies on the 'cholesterol fatty liver' of rats.** *Biochem. J.*, 1954, **58**, 301-306. [Banting and Best Dept. Med. Res., Univ. Toronto.]

In experiments similar to those described in the preceding abstract, choline, betaine hydrochloride, vitamin B₁₂ or inositol was given to rats fed on hypolipotropic diets containing 0.2, 0.4, 0.8 and 1.6 per cent. cholesterol.

The excessive deposition of glycerides and cholesterol esters was prevented by the addition of choline or betaine to the diet containing 0.2 per cent. cholesterol, but not with more. Vitamin B₁₂ had a much greater lipotropic effect on liver glycerides than on cholesterol esters. Inositol was without lipotropic effect.—G. A. Garton.

2303

RIDOUT, J. H., PATTERSON, J. M., LUCAS, C. C. and BEST, C. H. **Effects of lipotropic substances on the cholesterol content of the serum of rats.** *Biochem. J.*, 1954, **58**, 306-312. [Banting and Best Dept. Med. Res., Univ. Toronto.]

Free and total cholesterol were estimated in serum of some rats in the study reported in the preceding abstracts. When the diet contained lipotropic agents and excess cholesterol the post-prandial rise of bound serum cholesterol was related to the amount of cholesterol in the ration; increased amounts of dietary lipotropic substances, e.g., choline, produced no further effect. The elevated serum cholesterol values returned slowly to normal after about 18 to 24 hr. The bound serum cholesterol values of animals fed on purified hypolipotropic diets fell progressively during the experiment. Choline or betaine or vitamin B₁₂ quickly restored serum cholesterol to normal; inositol was ineffective.

It is concluded that lipotropic substances which prevent or cure fatty livers are also involved in the regulation of serum cholesterol, though the present findings do not support claims that lipotropic compounds reduce the level of bound cholesterol in serum.—G. A. Garton.

2304

DUFF, G. L., BRECHIN, D. J. H. and FINKELSTEIN, W. E. **The effect of alloxan diabetes on experimental cholesterol atherosclerosis in the rabbit. 4. The effect of insulin therapy on**

the inhibition of atherosclerosis in the alloxan-diabetic rabbit. *J. Exp. Med.*, 1954, **100**, 371-380. [Dept. Pathol., Pathol. Inst., McGill Univ., Montreal.]

For previous parts see Absts. 5155, Vol. 19 and 5431, Vol. 20.

Rabbits were fed on chow and water to appetite and 50 were injected with alloxan, but only 6 diabetic animals survived to complete the experiment. When their metabolism was stabilised they received 0.75 g. cholesterol in 15 ml. maize oil daily, and 4 to 6 days later insulin treatment began. From 57 to 90 days after first receiving cholesterol the survivors were killed. Controls were 18 rabbits which received cholesterol, but not alloxan or insulin; 9 of these died.

The extent of atherosclerosis in the aorta was not greater in the alloxan-diabetic rabbits treated with insulin than in controls.

In a second experiment there were 16 survivors after alloxan injection; all 16 and 13 controls received cholesterol and 10 of the diabetic rabbits received insulin. Diabetic rabbits had the highest average serum cholesterol levels, insulin-treated rabbits came next and controls had the lowest levels, but the differences were not great. The atherosclerosis was slight in diabetic rabbits and extensive in the other groups, especially in the treated diabetic group.

It was concluded that the inhibition of experimental atherosclerosis in alloxan diabetes was reduced by insulin and that it was associated with the diabetic state and not a direct effect of alloxan. The diabetes was never completely controlled by the insulin treatment.—D. Duncan.

2305

GOLDNER, M. G., LOEWE, L., LASSER, R. and STERN, I. **Effect of caloric restriction on cholesterol atherogenesis in the rabbit.** *Proc. Soc. Exp. Biol. Med.*, 1954, **87**, 105-108. [Jewish Chronic Dis. Hosp., Brooklyn, N.Y.]

Groups of adult rabbits were fed on restricted amounts of a commercial diet with or without 1 or 2 g. cholesterol daily for several weeks; control groups were allowed the same diet to appetite. Blood samples were taken periodically for estimation of fatty acids, lipid P, total cholesterol and lipoproteins. At the end of the experiments the animals were killed and the aortas were examined for arteriosclerotic changes.

Rabbits which received severely restricted diets with cholesterol showed significantly higher blood cholesterol, fatty acids, phospholipids and lipoproteins. The degree of these changes, and also of the arteriosclerosis induced, was greater than in control groups given the same amount of cholesterol.—G. A. Garton.

WEISS, S. B., HENKIN, G. and MARX, W. **Cholesterol balance studies in mice with modified thyroid activities.** *Proc. Soc. Exp. Biol. Med.*, 1954, **86**, 800-803. [Dept. Biochem. Nutrit., Sch. Med., Univ. S. California.]

Total cholesterol balance was studied on groups of 6 to 10 mice. Two groups of females and 2 of males were pair-fed on a Purina chow diet containing 0.65 per cent. cholesterol; one group of females was given 0.4 per cent. dried thyroid, one group of males 0.5 per cent. thiouracil, and the other group of males received both thyroid and thiouracil.

In animals which received thyroid the cholesterol output was significantly smaller than the intake and also significantly less than that recovered from the controls. The cholesterol recovery of animals given thiouracil exceeded 100 per cent. When a diet low in cholesterol (0.15 per cent.) was given to appetite to 2 groups of mice, one of which was given thyroid and thiouracil and the other thiouracil only, cholesterol recovery was significantly greater than intake in the hyperthyroid group and even greater than that of hypothyroid mice.—G. A. Garton.

BRAGDON, J. H. **Hyperlipemia and atheromatosis in a hibernator, *Citellus columbianus*.** *Circulation Res.*, 1954, **2**, 520-524. [Lab. Metabol., Nat. Heart Inst., Bethesda, Md.]

Groups of a total of 23 ground-squirrels (*Citellus columbianus*) were fed to appetite for 3 to 18 months on a high- or low-fat vegetable diet or commercial rabbit pellets with and without the addition of 1 per cent. cholesterol. From time to time the serum was analysed for total and free cholesterol, lipid P and total fat; triglyceride values were obtained by difference. Similar estimations were made on 5 animals after 10 weeks of hibernation in a cold room at 5° C. Twenty-one of the squirrels were killed at the end of the experiment and examined for atheromatous lesions of the heart and thoracic aorta.

Vol. 25, No. 2

Extremely high serum lipid values were often found in the non-hibernating animals, especially in the group fed on the high-fat diet. Triglycerides predominated and values were as high as 10 g. per 100 ml. serum; cholesterol and phospholipid values were among the highest recorded for any mammalian species. Cholesterol feeding did not produce high blood levels of sterol. Hibernation resulted in relatively low serum triglyceride values. Atheromatous lesions were found in the 3 animals with the highest serum cholesterol values.

PORTWICH, F., LEUFOLD, F. and BÜTTNER, H. **Über die alimentäre Plasmalogenämie beim Menschen.** [Plasmalogens of dietary origin in human blood.] *Deutsch. Ztschr. Verdauungs- u. Stoffwechselerk.*, 1954, **14**, 174-177. [Med. Klin., Univ. Kiel.]

When 10 normal subjects took 200 or 300 g. ox brain by mouth, acetalphosphatide in the serum rose to a peak after 10 or 12 hr. and returned to normal after 48 to 60 hr. The mean increase was 70 per cent. When the ox brain was given to 2 subjects as a homogenate by duodenal tube the peak was reached after 7 to 9 hr., otherwise results were similar. The peaks of serum lipid and cholesterol occurred earlier, 1½ to 2 and 2 to 3 hr. after the meal.—D. Duncan.

ANNISON, E. F. **Studies on the volatile fatty acids of sheep blood with special reference to formic acid.** *Biochem. J.*, 1954, **58**, 670-680. [Agric. Res. Coun. Inst. Animal Physiol., Babraham, Cambridge.]

A procedure is described for extraction of the volatile fatty acids in 10 to 20 ml. blood, for chromatographic analysis by the procedure of James and Martin (Abst. 77, Vol. 22). Formic acid was identified as a constituent of sheep blood to the extent of 10 to 30 per cent. (molar) of the volatile fatty acid present; the acid was also identified chromatographically in the blood of man, goats, cattle, horses, rabbits, cats and dogs. Arterio-venous comparisons did not show the uptake (or production) of appreciable amounts of formate by the actively secreting mammary gland of the goat or the head of the sheep. The total amount of formate in the digestive tract of the sheep was probably insufficient to account for the major part of the blood formate. Sheep urine contained traces of volatile fatty acids, including formate. In sheep and cattle, distribution of volatile fatty acids between cells and plasma indicated that formate was concentrated in the cells.

CLAASSEN, V., VOGELS, R. J., and WÖSTMANN, B. Extrahepatic formation of plasma phospholipids in rats. *Acta physiol. pharmacol. neerl.*, 1951-1952, 2, 553-559. [Netherlands Inst. Nutrit., Amsterdam.] French and German summaries.

Radio-active phosphate was injected into the marrow cavity of the femurs of adult rats. The

animals were killed 5, 12, 15 and 60 min. later. Liver and plasma phospholipids were isolated and their radio-activity was measured.

In all the specific activity of the plasma phospholipids was greater than that of the liver phospholipids, indicating that plasma phospholipids were synthesised outside the liver.—G. A. Garton.

ACKERMANN, P. G. and TORO, G. Calcium balance in elderly women. *J. Gerontol.*, 1954, 9, 446-449. [St. Louis Chronic Hosp., Mo.]

The subjects were 7 women aged from 68 to 83 years and one only 48 years old but at least 5 years past menopause; all were physically fairly healthy and without marked osteoporosis. They

were on an accurately regulated and well balanced diet providing 35 Cal. per kg. bodyweight daily and all were in positive N balance. Four subjects were tested on 3 levels of Ca intake and 4 on 2 levels. Balance tests lasted 45 or 60 days, with 15 or more days for adjustment beforehand.

The intake in mg. Ca per kg. bodyweight daily when plotted against the balance in the same units gave a regression line intersecting the horizontal axis at an equilibrium intake of 16.7 mg. per kg. The value for elderly men on the same diet at the same time (Abst. 798, Vol. 24) was 18.6 mg. per kg. The value of 16.7 mg. per kg. is much higher than those reported for young adults.—D. Duncan.

2318

ACKERMANN, P. G., TORO, G., KOUNTZ, W. B. and KHEIM, T. The effect of sex hormone administration on the calcium and nitrogen balance in elderly women. *J. Gerontol.*, 1954, 9, 450-455. [St. Louis Chronic Hosp., Mo.]

The subjects were 7 of the women used in the preceding study, and received the same diet. Six of them received 1 mg. oestradiol benzoate in oil intramuscularly twice weekly, the seventh acted as control. Menstruation was later induced in 3 subjects by cyclic withdrawal of oestradiol during one week in each month, and in the other 3 by administration of progesterone on 3 successive days each month.

No effect was found on the N balance, but the 3 subjects initially in negative Ca balance increased their retention. Later administration of large doses of testosterone propionate, 30 mg. daily for 30 days, to 2 subjects greatly increased their retention of both N and Ca, but similar doses of progesterone were less effective.—D. Duncan.

NORDIN, B. E. C. and FRASER, R. The effect of intravenous calcium on phosphate excretion. *Clin. Sci.*, 1954, 13, 477-490. [Dept. Med., Postgrad. Med. Sch., London.]

Five normal young adults and 9 patients not suffering from bone disease, 7 patients with osteomalacia and 10 with osteoporosis were given a

N.A. and R., April 1955

diet containing 100 mg. Ca and 500 to 700 mg. P daily for 3 days before administration of 15 mg. Ca per kg. bodyweight by intravenous infusion in 4 hr. Urine samples were collected at intervals for 24 hr. starting 4 hr. before infusion, and blood samples were taken at the beginning and end of the infusion and 4 and 20 hr. later for estimation of P, Ca and creatinine.

The infusions of Ca produced a decrease in urinary phosphate and a rise in blood phosphate and hence a decrease in the phosphate: creatinine clearance ratio, which reached its lowest level 12 hr. after the beginning of the infusion. The fall was less pronounced with infusions of 8 mg. Ca per kg. bodyweight and was even more pronounced with infusions of 30 mg. Ca per kg. bodyweight. In 2 hypoparathyroid patients there was a rise in the phosphate: creatinine clearance ratio and in urinary P. In the 7 osteomalacia patients the phosphate: creatinine clearance ratio was abnormally high; Ca infusion caused the greatest decrease in the ratio among this group. The administration of 200 U.S.P. units of parathyroid hormone after the infusion of Ca and at the point of maximum depression of phosphate output caused a phosphate diuresis; the absolute rise in hourly phosphate output was the same as that obtained without preceding Ca infusion, but the percentage increase in phosphate: creatinine clearance was greater when the hormone was given after Ca infusion.—G. F. Garton.

SHIRLEY, R. L., JETER, M. A., FEASTER, J. P., MCCALL, J. T., OUTLER, J. C. and DAVIS, G. K. Placental transfer of ^{99}Mo and Ca^{45} in swine. *J. Nutrition*, 1954, **54**, 59-64. [Dept. Animal Husb., Univ. Florida, Gainesville.]

Two sows weighing 299 and 308 lb. during their first pregnancy received, 6 days before the expected date of parturition, 0.9 mC. of ^{99}Mo as sodium molybdate and 0.3 mC. of ^{45}Ca as chloride, in water by stomach tube. Two other sows, weighing 335 and 300 lb. during their second pregnancy, received in the same way 3.16 mC. of ^{99}Mo and 0.87 mC. of ^{45}Ca . All were killed 30 hr. later, after urine and faeces had been collected.

The distribution of the isotopes in the foetal and maternal tissues is tabulated. Very little Mo crossed the placenta, although the concentration in the maternal tissues was high. ^{45}Ca was as widely distributed in the foetal tissues as in those of the sow, and was especially concentrated in the foetal bones.

Most of the ^{99}Mo given was absorbed; on the average 54.7 per cent. of the dose was excreted in urine in the 30-hr. experiment, and only 8.19 per cent. in the faeces, 3 per cent. remaining in the digestive tract. Of the ^{45}Ca , on the other hand,

47.03 per cent. was excreted in the faeces, 6.3 per cent. remained in the digestive tract and only 0.25 per cent. appeared in the urine.—D. Duncan.

2321

HANSARD, S. L. and PLUMLEE, M. P. Effects of dietary calcium and phosphorus levels upon the physiological behavior of calcium and phosphorus in the rat. *J. Nutrition*, 1954, **54**, 17-31. [Univ. Tennessee—Atomic Energy Commission Agric. Res. Programme, Oak Ridge.]

Four groups of weaned rats were fed on diets containing 0.013, 0.3, 0.5 and 1.0 per cent. Ca for 55 days. They were then given radio-active Ca and placed in metabolism cages for 4 days, and were finally killed for analysis.

The low-Ca group showed gross rickets after 55 days on the diet and their weight was only 62 per cent. of that of the other groups. There was no liveweight or other clinical difference between the other 3 groups.

Absorption of dietary Ca was 98 per cent. in the low-Ca group and 45 per cent. in the high-Ca group and there was an increase in endogenous faecal Ca from 8 mg. per kg. bodyweight in low-Ca to 50 mg. in high-Ca animals. From these data daily Ca maintenance requirements for the 3 groups which were apparently normal, receiving diets containing 0.3, 0.5 and 1.0 per cent. Ca, were 5, 11 and 21 mg. Ca.

A larger proportion of radio-active Ca was retained by rats on the low-Ca diets than by those on the high-Ca diet, but the distribution of retained Ca did not differ significantly.

Radio-active P administered to rats reared on low-Ca (0.013 per cent.) and on optimum-Ca (0.5 per cent.) diets was absorbed readily by both groups, but less was retained on the low-Ca than on the optimum-Ca diet.—R. Hill.

2322

BHARUCHA, R. P. and MCCAY, C. M. The retention of calcium from gypsum and phytin by the albino rat in relation to life span. 1. *J. Gerontol.*, 1954, **9**, 439-445. [Dept. Animal Nutrit., Cornell Univ., Ithaca, N.Y.]

The 160 weanling rats were divided into 4 groups on different diets, and 6 males and 6 females from each group were used for 10-day balance studies every 30 or 40 days up to 180 days of age and every 90 to 100 days thereafter. When animals died or became ill they were replaced by healthier animals; this may explain a rise in the Ca balance at 462 days. At the time of each balance trial a rat of each sex from each group was killed for bone studies, but after 270 days only one more lot were killed, at 460 days. The diets contained

(1) 0.3 per cent. Ca phytate and white flour; (2) 0.3 per cent. CaSO_4 and whole wheat flour; (3) 0.6 per cent. CaSO_4 and whole wheat flour; and (4) 0.3 per cent. CaSO_4 and potato flour. These 4 mixtures made up 69 per cent. of the diet, and the other 31 parts consisted of brewer's yeast 10, casein 5, salt mixture without Ca 3, cottonseed oil 10 and cod liver oil 3. The protein content was 15 per cent.

Growth of females was similar on all 4 diets. Males on diet 3, with the highest CaSO_4 intake, became larger than the others, their greatest mean weight being 475 g. against 400 g. Rats on the Ca phytate and white flour diet had rough yellow coats, those on potato flour were very smooth. There was no significant difference in mortality at the 5 per cent. level related to diet, but females outlived males by 113 days.

There was greater retention of Ca from CaSO_4 in the first year. The rats with least available Ca, on the first 2 diets, went into negative balance later than those on the other 2 diets. Except on diet 3, males tended to go into negative balance before females. All were still in positive balance at 280 days of age, and bone volume continued to increase. Differences in percentage of bone Ca were highly significant at the 1 per cent. level; the availability of Ca in the 4 diets by this criterion was, in descending order, diets 4, 3, 2 and 1.

CANALS, E., MARIGNAN, R. and CORDIER, S. Recherches sur la médication phosphorée et calcique. Étude des inosito-hexaphosphates. [Research on phosphorus and calcium therapy. Study of the inositol hexaphosphates.] *Bull. Soc. Chim. biol.*, 1954, **36**, 1015-1020. [Lab. Phys., Fac. Pharm., Montpellier.]

Barley was grown in culture solution containing orthophosphoric acid labelled with ^{32}P , and labelled phytin was obtained from the grain and administered to growing cats, rabbits, mice and rats.

Rabbits fixed in their tissues more phytin ^{32}P than did cats of similar age; a kitten of 15 days, fed only on milk, fixed more than one aged $2\frac{1}{2}$ months and fed on meat, but still less than the rabbits. Rats fixed slightly more in the brain, liver and kidneys than rabbits, much more in muscle and bone, which supports the view that the rat has an intestinal phytase. Mice were intermediate between cats and rabbits; they fixed in bone on the average 13 per cent. of the total ^{32}P of phytin, but 24 per cent. of that from tricalcium phosphate.

Commercial phytin reduced the utilisation of ^{45}Ca from a labelled salt in young mice, but only when they received the high dose of 10 mg. phytin daily for 4 days.—D. Duncan.

2324

CLAASSEN, V. and WÖSTMANN, B. S. J. Verschillen tussen de opnemng van Ca^{45} en P^{32} in het skelet van jonge ratten na intraveneuze injectie. [Difference between uptake of ^{45}Ca and of ^{32}P in the skeleton of young rats after intravenous injection.] *Chem. Weekblad*, 1954, **50**, No. 2, 18-21. [Lab. Physiol. Chem., Univ. Amsterdam.]

When ^{45}Ca and ^{32}P are injected into growing rats on a rachitogenic diet with or without vitamin D, about 85 per cent. of ^{45}Ca is taken up by the skeleton in the first hour but only 19 per cent. of ^{32}P . Equations are set up to express the rate of uptake on the assumption that it occurs by exchange at the surface of the bone crystal. Absorption of P by the skeleton is profoundly affected by its ready uptake in other tissues.

When rachitic and normal animals are compared, there is little difference in uptake of ^{32}P by the rat femur at 15 min., but at 24 hr. twice as much has been taken up by the normal femur and very little more by the rachitic femur than was taken up in 15 min. Since the rate of decrease of specific activity of plasma was similar in normal and rachitic groups, the failure of deposition of ^{32}P in rickets is probably to be attributed to the deficit of inorganic P in plasma, 30 μg . per ml., as compared with 65 μg . per ml. in normal rats.

BERGER, M., CIER, A. and CIER, J. F. Étude de la croissance et de la minéralisation de greffes de tissu osseux chez le rat blanc. [Growth and mineralisation of bone grafts in the white rat.] *Arch. Sci. physiol.*, 1954, **8**, 357-375. [Lab. Phys. Biol., Inst. Physiol., Lyons.]

Pieces of tail from young rats aged about 20 days were implanted under the skin of the back of host rats of different ages. After from 3 to 64 days the host received 1 μC . of ^{32}P as phosphate by intraperitoneal injection and was killed 24 hr. later. The tail of the host served as control. Total Ca, P and N and ^{32}P were estimated in homogenated digests of graft and control.

In normal tails protein N increased rapidly during growth, but after reaching about 3.10 per cent. of fresh tissue at the 40th day it remained remarkably constant, though in animals aged 500 days or more it tended to be less. The ratio Ca : N rose slowly from the 20th to about the 70th day and then rapidly until the 100th, when it stabilised at about 5. In the old rats it was about 2.4. The P : N ratio behaved similarly. The Ca : P ratio was about 2.3 at all ages. The amount of ^{32}P fixed in 24 hr. fell regularly and rapidly until the 100th day and thereafter did not vary significantly with age. It was considered to indicate the relative rate of calcification of the protein matrix.

N.A. and R., April 1955

Grafts placed in hosts of the same age as the donor accumulated Ca and P at the same rate as the hosts' tails; the curves were almost identical. Until the 21st day after grafting the grafts took up ^{32}P at about the same rate as the controls, but after this they took up a little more. The adaptation of the graft tissue was thus rapid and complete.

Grafts placed in hosts of 100 days were less regular in behaviour. Of 14 grafts examined 16 to 64 days after insertion 9 had not grown, 3 had grown well and 2 had grown well and also calcified. Total N in the grafts fell in the first week and then rose rapidly in the grafts which took, but in the others it remained low. Ca and P rose from the second week onwards in most grafts. Calcification tended to be more rapid but less regular than in grafts in young hosts. Fixation of ^{32}P was from 5 to 37, on the average 12, times that in the host's tail.

Grafts placed in senescent rats aged about 500 days made little or no linear growth in 5 rats but grew well in 2. Calcification was regular, not rapid and erratic as in the adult rats. The Ca:P ratio was low, mean 1.9. The graft fixed 7 to 41 times as much ^{32}P as the control. N increase was irregular.—D. Duncan.

TAYLOR, S. **Calcium as a goitrogen.** *J. Clin. Endocrinol.*, 1954, **14**, 1412-1422. [Dept. Surg., Post-grad. Med. Sch., Univ. London.]

Two groups of rats were fed on low-iodine diet containing 358 mg. Ca per 100 g. One group was given 2 per cent. CaCO_3 in addition. A third group was given KI in drinking water. At the end of 6 weeks the rats weighed on the average $150 \text{ g.} \pm 1.0$, 169 ± 3.3 and 200 ± 6.9 respectively. They were then given ^{131}I in $5\text{-}\mu\text{C.}$ doses by intraperitoneal, subcutaneous, or stomach tube injections according to the requirements of the experiments. The radio-activity of the thyroids was measured every 2 hr. and the radio-activity of the alimentary tract after death. The addition of CaCO_3 to the diet increased thyroid weight and ^{131}I uptake, but Ca had little or no effect on the absorption of ^{131}I from the gut. Injection of 50 mg. sodium thiocyanate showed that much of the accumulated ^{131}I was not protein-bound, and most of it was discharged. On the other hand, excess I prevented the goitrogenic action of the high Ca intake, and in this respect Ca differed in its goitrogenic effect

from the thiourea compounds. The mode of action of CaCO_3 in producing goitre is discussed.

KLEIN, P. D. and JOHNSON, R. M. **Phosphorus metabolism in unsaturated fatty acid-deficient rats.** *J. Biol. Chem.*, 1954, **211**, 103-110. [Detroit Inst. Cancer Res., Mich.]

Male rats weaned at 18 days of age were fed on a fat-deficient diet or a similar diet containing 5 per cent. maize oil. After 14 weeks 4 animals from each group were each given a single subcutaneous injection of $0.45 \mu\text{C.}$ of $\text{Na}_2\text{H}^{32}\text{PO}_4$ per g. body-weight; 4 hr. later they were killed and the livers were removed for estimation of acid-soluble inorganic and organic P, phospholipin, phosphoprotein, deoxypentose nucleic acid (DNA) and pentose nucleic acid (PNA); fractions were assayed for radio-activity and, if appropriate, N content.

No difference in the uptake of ^{32}P into phosphoprotein, phospholipin, DNA or PNA was found between normal and fat-deficient rats. Since after 4 hr. the incorporation of ^{32}P into the acid-soluble P fractions had passed its maximum (Abst. 3258, Vol. 13), the lower specific activity of the acid-soluble organic P found in the livers of fat-deficient animals could not definitely be ascribed to a difference in the rate of incorporation of ^{32}P . The experiment was therefore repeated and the animals were killed 75 min. after injection of the isotope, to correspond with the rate of maximum incorporation of ^{32}P into the acid-soluble P fraction and to precede the time of maximum ^{32}P incorporation into the acid-soluble organic P fraction. No significant difference was observed between the specific activities of the acid-soluble inorganic P in the livers of either group, but the specific activity of the acid-soluble organic P in the livers of the animals given the fat-deficient diet was significantly lower than that found in the rats fed normally.

Further studies *in vitro* on the liver tissue from both diet groups of rats showed no difference in anaerobic glycolysis, suggesting that the decreased uptake of ^{32}P into the acid-soluble organic P fraction in the livers of the fat-deficient animals is related to a dissociation of oxidation from phosphorylation accompanying the oxidation of intermediates in the Krebs cycle by the DPN-linked dehydrogenases.—G. A. Garton.

KUNKEL, H. G. and BEARN, A. G. **Phospholipid studies of different serum lipoproteins employing P_{32} .** *Proc. Soc. Exp. Biol. Med.*, 1954, **86**, 887-891. [Hosp., Rockefeller Inst. Med. Res., New York.]

Each of 3 normal subjects and 3 with mild liver disease was given about 0.2 mC. of $\text{Na}_2\text{H}^{32}\text{PO}_4$ by

mouth, and blood samples were taken after 6, 12, 24 and 48 hr. Serum lipoproteins were separated electrophoretically and the radio-activity of the different fractions was estimated after extraction of the phospholipins with ethanol and ether.

The phosphate labelled the α_1 , α_2 and β -lipoproteins; after ordinary meals both the phospholipoid P and the radio-activity of the α_2 -lipoprotein fraction increased. Specific activities of several lipoproteins were similar at different times after the administration of ^{32}P . In experiments *in vitro* the transfer of phospholipid radio-activity from labelled β -lipoproteins to unlabelled α_1 -lipoproteins and from labelled α_1 -lipoproteins to unlabelled β -lipoproteins was demonstrated.

SHERLEY, R. L., DRIGGERS, J. C., MCCALL, J. T., NIENBERG, M. and DAVIS, G. K. The rate of deposition and turnover of P^{32} and Ca^{45} in the tissues of the laying hen. *Poultry Sci.*, 1954, 33, 932-936. [Dept. Animal Husb., Univ. Florida Agric. Exp. Stat., Gainesville.]

Ten laying hens and 2 just out of production were injected in the gastrocnemius and breast muscles with 100 μC . of ^{32}P and 50 μC . of ^{45}Ca and were killed after 0.25, 0.5, 1, 2, 3, 8, 24, 96, 98, 240 and 504 hr.

In the bones, both elements reached a maximum concentration 1 to 3 hr. after administration, which remained constant to 240 hr. and then fell. Of the bones studied the pubis and atlas contained least isotope.

^{32}P reached a maximum concentration of 0.05 per cent. in the lungs, spleen, pancreas, brain and bile and slightly more in the heart. Within 2 hr. of the injection, the liver contained 17 per cent., and still 1 per cent. between 240 and 504 hr. The kidney contained a maximum of 6.5 per cent. after 3 hr. Muscles, magnum and uterus reached a maximum after 24 hr., ovaries at 96 hr., but no turnover was observed in the last during 21 days.

^{45}Ca was found in the non-osseous tissue at a very low level, only traces remaining after a few hours.

The daily excreta of the first 3 days contained 15, 7 and 4 per cent. of the ^{32}P dose and 2, 1 and 0.8 per cent. of the ^{45}Ca dose. Thereafter the excreta contained daily about 2.2 per cent. of the ^{32}P and 0.2 per cent. of the ^{45}Ca .—M. J. Head.

WILCOX, R. A., CARLSON, C. W., KOHLMAYER, W. and GASTLER, G. F. The availability of phosphorus from different sources for poult fed purified diets. *Poultry Sci.*, 1954, 33, 1010-1014. [Dept. Poultry Husb., S. Dakota Agric. Exp. Stat., College Station.]

In each of 5 experiments, 10 groups of 20 to 22 day-old poult were given a synthetic ration with 0.06 per cent. P for 4 weeks. The following P supplements were given at 0.8 and 1.0 per cent. levels: (1) dibasic Ca phosphate U.S.P., (2) monobasic Ca phosphate, (3) tribasic Ca phosphate, (4) β tricalcium phosphate, (5) steamed bonemeal, (6) (7) and (8) different defluorinated calcium phosphates, (9) and (10) different commercial dicalcium phosphates, (11) and (12) different rock phosphates, (13), (14) and (15) different colloidal phosphates. CaCO_3 was used to balance the supplementary P.

Supplements 1, 2, 7 and 8 were the most suitable and 11, 12, 13, 14 and 15 were unsuitable; the remainder were intermediate. It is not known why there was such a large variation in the usefulness of the same product from different sources.

EDELMAN, I. S., JAMES, A. H., BROOKS, L. and MOORE, F. D. Body sodium and potassium. 4. The normal total exchangeable sodium;

N.A. and R., April 1955

its measurement and magnitude. *Metabolism*, 1954, 3, 530-538. [Dept. Surg., Peter Bent Brigham Hosp., Boston, Mass.]

For parts 2 and 3 see Abst. 865, Vol. 25.

Total exchangeable Na in tissue and red cells from men, women and dogs, all healthy, was calculated after intravenous injection of ^{24}Na as the difference between ^{24}Na injected and that excreted in the urine, divided by the serum specific activity ($^{24}\text{Na}/^{23}\text{Na}$). From the ratio of serum to tissue specific activities equilibrium of distribution was deemed complete 15 to 24 hr. after injection in skin, skeletal and smooth muscle, gastric mucosa and red cells in man, and in skin, skeletal muscle, kidney, brain, liver, heart and red cells in dogs. The mean total exchangeable Na in 21 men was 40.9 and in 6 women 37.8 m. equiv. per kg. bodyweight. The results agree with those in the literature and no trend based on age or sex was revealed, although numbers were insufficient to eliminate statistical differences. The normal standard for human adults was estimated to be 41.0 ± 5 m. equiv. per kg. bodyweight.—A. Hepburn.

2338

IKKOS, D., LUFT, R. and SJÖGREN, B. Distribution of fluid and sodium in healthy adults. *Metabolism*, 1954, 3, 400-404. [Div. Endocrinol., Dept. Int. Med., Serafimerlasarettet, Stockholm.]

Five healthy men and 4 women, aged 21 to 60 years, were subjects in a simultaneous estimation of total body water with antipyrine, of total exchangeable Na with ^{24}Na and of extracellular water with inulin and thiosulphate.

With inulin, intracellular water appeared to represent 70.1 ± 0.7 per cent. and extracellular water 29.9 ± 0.7 per cent. of total body water; the ratio of intracellular to extracellular water was 2.4 ± 0.1 . With thiosulphate the figures were 69.5 ± 0.8 , 30.5 ± 0.8 and 2.3 ± 0.1 . If the figure for inulin space was used, intracellular Na represented 39.7 ± 1.5 per cent. of total exchangeable Na; the mean intracellular Na content was 42.4 ± 2.0 m. equiv. per litre of intracellular water. Extracellular Na represented 60.3 ± 1.5 per cent. of total exchangeable Na. With the figure for thiosulphate space, the corresponding Na figures were 38.8 ± 1.4 , 41.7 ± 1.7 and 61.2 ± 1.4 .

CHEEK, D. Total body chloride of children in potassium deficiency and under circumstances of poor nutrition. *Pediatrics*, 1954, 14, 193-200. [Dept. Paediat., Univ. Toronto.] Spanish summary.

The methods and technique used in a previous study of normal children (Cheek, *J. Appl. Physiol.*,

1953, 5, 639; Abst. 653, Vol. 25) were applied to the study of 9 children with malnutrition and 8 with K deficiency. The first group consisted of 2 with liver disease and low blood protein, 2 with undiagnosed dystrophy and 5 with fibrocystic disease of the pancreas. In this group there was an increase of extracellular water and of total chloride per unit bodyweight, except in one infant with fibrocystic disease of the pancreas who was studied during a heat wave. This infant showed, in terms of bodyweight, loss of extracellular water and of chloride. Subjects with K deficiency were in 2 groups of 4. One group had chronic diarrhoea and were receiving glucose and hypotonic saline intravenously. The other children were in a state of electrolyte depletion, untreated. The first group showed raised extracellular water and total chloride. In the second group there were chloride deficits and, with one exception, reduction of extracellular water. This last responded to KCl administration with an increase in total chloride and clinical improvement. Administration of potassium lactate by vein and KCl and calcium gluconate by mouth to one of the first group caused a reduction of extracellular water and a return to normal total chloride.—F. C. Aitken.

ROMNEY, S. L., MERRILL, J. P. and REID, D. E. Alterations of potassium metabolism in pregnancy. *Amer. J. Obstet. Gynecol.*, 1954, 68, 119-130. [Dept. Obstet., Harvard Med. Sch., Boston, Mass.]

The histories of 4 patients are discussed: one with low blood K and 3 with high. Electrocardiograms were used to confirm the alteration of blood K levels. The first woman's blood K became low in association with the severe dehydration of *hyperemesis gravidarum*: intravenous K resulted in dramatic improvement. The 3 high levels arose from anuria in association with, respectively, eclampsia, toxic separation of the placenta, and uterine atony after caesarean section. Of these patients the first died 5 days after induction of labour and spontaneous delivery, dialysis with an artificial kidney having been considered and a decision deferred. The second recovered well after dialysis. In the third, dialysis caused improvement which was not maintained, probably because of severe renal damage, but ACTH therapy produced a favourable response.—A. M. Thomson.

FREED, S. C., ROSENMAN, R. H. and SMITH, M. K.
Effect of adrenalectomy upon the pressor action of potassium in hypotensive, potassium-deficient rats. *Circulation Res.*, 1954, 2, 494-498. [Harold Brunn Inst. Cardiovascular Res., Mount Zion Hosp., San Francisco, Calif.]

The low blood pressure of rats depleted of K on a low-K diet was restored to normal in intact rats by parenteral administration of K. In K-depleted rats adrenalectomised 1 or 3 days previously there was only a slight rise in blood pressure in response to parenteral K. The spontaneous retention of K which occurred in K-deficient rats during 30 days after adrenalectomy failed to induce spontaneous recovery of their low blood pressures.

RACE, G. J. and PESCHEL, E. Pathogenesis of polyarteritis nodosa in hypertensive rats. *Circulation Res.*, 1954, 2, 483-487. [Dept. Pathol., Sch. Med., Duke Univ., Durham, N.C.]

High blood pressures were produced in 80 young female rats by a technique to be described in another paper (Kempner *et al.*, *Circulation Res.*, 1955, 3, 73). These rats were then divided into 5 groups of 10 to 22 and received the following diets: rice with 25 to 50 mg. NaCl daily; rice and meat with 25 to 75 mg. NaCl daily; rice with 75 mg. NaCl daily for 1 to 3 weeks, then without NaCl; a mixed diet of carbohydrate and small amounts of protein, with 75 mg. NaCl daily; rice with 50 to 250 mg. NaCl daily. The 20 normal controls received dog chows containing 200 mg. NaCl daily. The rats with high blood pressure died at ages of from 54 to 454 days with a mean of 127 days, and the means for the different diet groups were similar. Controls were killed at intervals. All were examined histologically for arterial lesions.

The incidence of *polyarteritis nodosa* in the experimental rats was 31.2 per cent. None was found in controls. The initial arterial lesion produced fibrinoid necrosis of the intima, the repair of which led to fibroblastic proliferation throughout the wall and extensive scarring.

LESCHI, J. Action d'un régime riche en chlorure de sodium sur le poids des glandes surrénales du rat blanc en période de croissance. [Effect of a diet rich in sodium chloride on the weight of the adrenals of the white rat during growth.] *C.R. Acad. Sci.*, 1954, 239, 720-721.

Groups of young rats received from weaning to the age of 2 or 2½ months diets differing in salt content. The low-salt diet contained, per cent., wheat 87, casein 10, cod liver oil 2 and CaCO₃ 1, with distilled water to drink; the high-salt diet

contained NaCl 2 and NaHCO₃ 2 per cent., at the expense of wheat, with 1 per cent. salt solution to drink. In an experiment run from January to March the adrenals of both diet groups were heavier in relation to bodyweight than those in a similar experiment run from April to June. In both experiments the rats given salt had significantly larger adrenals than those on low salt intake.—D. Duncan.

ROSS, E. J. and SPENCER, A. G. Observations on cation exchange resins in the small and large intestines. *Clin. Sci.*, 1954, 13, 555-566. [Med. Unit, University Coll. Hosp. Med. Sch., London, W.C.1.]

Cation exchange resins were placed in isolated loops of rat small and large intestine and observations were made on the transfer of Na and K ions. By means of radio-active Na and K the absolute rates of transfer and the net exchange were calculated. In the small intestine the uptake per g. resin was 1.7 m. equiv. Na in the first hour; there was a simultaneous transfer off the resin of 0.7 m. equiv. during this time. The net rate of Na uptake was 1.0 m. equiv. per g. resin per hr. Corresponding values for K were 0.5 m. equiv. on and 0.2 equiv. off with a net transfer on to the resin of 0.3 m. equiv. per g. per hr. In the large intestine the rate of transfer of Na was 0.1 m. equiv. per g. hr. on the resin and 0.45 m. equiv. per g. per hr. off the resin with a net exchange of -0.35 m. equiv. per g. per hr. Corresponding values for K were 0.4 m. equiv. on and 0.02 m. equiv. off with a net exchange of 0.38 m. equiv. per g. per hr. Restriction of Na intake produced slower turnover rates for both Na and K in the small intestine and no significant difference in the rates of transfer in the large intestine, but the faecal excretion of Na bound to resin in a group on a low Na diet was only 25 per cent. of that in a normal group.

Adrenalectomised rats on normal Na intake excreted more Na and less K on the resin in the faeces than did normal rats; injection of deoxycorticosterone restored the faecal excretion of these cations to normal. Adrenalectomised rats on a low Na diet excreted less Na on the resin than did adrenalectomised rats on a normal diet, but the ability to conserve Na was considerably less in the adrenalectomised animals.—G. F. Garton.

VAN MIDDLESWORTH, L. Radioactive iodide uptake of normal newborn infants. *Amer. J. Dis. Child.*, 1954, **88**, 439-442. [Dept. Physiol., Univ. Tennessee Coll. Med., Memphis.]

The thyroid uptake of radio-active I in 7 normal newborn male infants was studied with a specially constructed scintillation counter. The

test dose of ^{131}I was drawn into a 0.25 ml. syringe with a 27-gauge needle. The gamma radiation in the syringe was counted. The test dose, which was between 1 and 1.5 μC ., was injected deeply into the gluteus maximus muscle of the infant and the gamma radiation in the syringe and needle was again counted, the difference being taken as the amount injected. After 24 hr. the thyroid area was examined and 3 counts of 1 min. each were recorded. The background was counted over the thigh and subtracted from the thyroid count. Corrections for radio-activity decay were also made. Thyroid uptake was computed as a percentage of the injected dose.

In 6 of the 7 infants, 60 per cent. of the ^{131}I was taken up and retained by the thyroids. Two of the infants accumulated 90 per cent. and the lowest amount collected was 46 per cent. These figures suggest that the newborn infant may experience a period of hyperthyroidism.

The results confirm previous investigations which established that in infants 1 to 3 days old, protein-bound I and butanol-extracted I values were compatible with hyperthyroidism. Stress is laid on the fact that the risks attendant on the use of radiation in the very young are unknown. The implications and precautions of the procedure are discussed.—B. W. Simpson.

HICKEY, F. C. and BROWNELL, G. L. Dynamic analysis of iodine metabolism in 4 normal subjects. *J. Clin. Endocrinol.*, 1954, **14**, 1423-1436. [Med. Res. Lab., Providence Coll., R.I.]

Iodine was assumed to be present in the body in 3 identifiable compartments: (1) inorganic iodide in plasma, extracellular fluid and thyroid tissue; (2) organic iodine in the thyroid; (3) organic iodine in the blood and extrathyroidal tissues. The object of this investigation was to find whether this 3-compartment model would explain the metabolism of iodine in normal man. Four comparable subjects from 32 to 48 years, weighing from 182 to 229 lb. and with B.M.R. from ± 0 to -10 per cent. were selected and injected with ^{131}I . Thyroid uptake, renal clearance rate and serum protein-bound iodine were studied for 3 weeks. The data were analysed and I equilibrium values were estimated with an analogue computer. Three of the 4 subjects appeared to be in I balance according to this method of assessment.

GLASCOCK, R. F. The secretion of a single tracer dose of labelled iodide in the milk of the lactating cow. *J. Dairy Res.*, 1954, **21**, 318-322. [Nat. Inst. Res. Dairying, Univ. Reading.]

A tracer dose of about 50 μg . radio-active potassium iodide was administered to a 12-year-old lactating Shorthorn cow and the radio-activity in the milk was measured. The maximum specific activity of the milk occurred on the first day and by the fifteenth day it fell to 0.5 per cent. of the maximum. The radio-activity in the milk was in the chemical form of iodide ion. There was some evidence that the specific activity of the urine was much higher than that of the milk.

HOGNESS, J. R., WONG, T. and WILLIAMS, R. H. ^{131}I excretion after injection of radiothyroxine into hyperthyroid, hypothyroid or normal rats. *Metabolism*, 1954, **3**, 510-517.

Rats of 200 to 240 g. weight were divided into 5 groups of 10: controls, rats given 0.2 per cent. propylthiouracil in the diet for 3 weeks before and during the experiment, rats thyroidectomised 3 weeks before the experiment, rats given subcutaneous injections of 50 μg . L-thyroxine twice daily for 8 days before and during the experiment and rats given subcutaneous injections of 5 mg. thyrotropin in saline twice daily for 4 days before and during the collection period of 4 days, when urine and faeces were separated and collected daily. On the first day all the rats were injected with 10 μC . (0.6 to 0.9 μg .) of ^{131}I -labelled L-thyroxine subcutaneously. Aliquots of the excreta were assayed for total radio-activity and other aliquots for radio-activity associated with thyroxine-like compounds.

The total faecal excretion was much the same for all except the thyroidectomised rats, whose faecal excretion was approximately half that of the others owing to constipation. At the end of 4 days the carcasses were assayed for residual activity and 90 per cent. of the initial activity was

accounted for in all groups. Calculated as a percentage of the dosage, the urinary radio-activity of the groups in order was 32, 17, 34, 41 and 29 and the faecal radio-activity 51, 64, 26, 43 and 51. The most striking features were the fall in urinary radio-activity and the rise in faecal radio-activity in the rats given propylthiouracil, the reduction in faecal activity associated with reduced faecal output in the thyroidectomised rats and the marked contrast between the second and third groups; and the similarity in total radio-activity excreted over the 4 days in all but the thyroidectomised group. Most of the changes observed may be explained on the basis of altered rates of renal and intestinal excretion.—B. W. Simpson.

FAWCETT, D. M. and KIRKWOOD, S. Role of the salivary glands in extrathyroidal iodine metabolism. *Science*, 1954, **120**, 547-548. [Dept. Chem., McMaster Univ., Hamilton, Ont.]

The submaxillary, parotid and sublingual glands of rats under Nembutal anaesthesia were removed and 100 μg . of diiodotyrosine labelled with 100 μC . of ^{131}I was injected into the jugular vein. A 0.5-ml. sample of blood was collected from the tail vein as soon as possible after the injection to give zero-time values for iodide and diiodotyrosine. Further samples were collected after 10, 30, 60 or more minutes. The proportions of iodide and diiodotyrosine were compared by counting over the appropriate spots on paper chromatograms with a Geiger counter. Control rats were treated in the same way, but the glands were left intact.

Injected diiodotyrosine remained in the blood of the operated rats, but disappeared very rapidly from the blood of the intact rats. The salivary glands had removed the I from the diiodotyrosine and returned it to the thyroid. It is suggested that the salivary glands have a major role in extrathyroidal metabolism of organic I in the body and act as "reverse thyroids".—B. W. Simpson.

ALLGRETTE, N. and AZABAGIĆ, S. Effect of iodine on the insular apparatus of the pancreas in the rat. *Arch. internat. Pharmacodyn.*, 1954, **98**, 369-372. [Inst. Physiol., Med. Fac., Univ. Zagreb.]

Three comparable groups of 10 rats weighing 106 to 152 g. were fed on a standard ration to appetite. Instead of water they were given solutions of 0.01 N NaCl, NH_4I and NaI, the average volumes consumed being 8.48, 8.26 and 6.65 ml. per rat daily. After 60 days the rats were killed; the pancreas of each was fixed and stained by the method of Gomori, and alpha and beta cells of the islets of Langerhans were counted.

N.A. and R., April 1955

The proportion of beta to alpha cells was normal in the group which had NaCl, but in both groups given iodides the ratio was significantly depressed. Na, NH_4 and Cl ions did not induce any change in the ratio, but the depressive effect of the iodide ions was highly significant at $P < 0.001$. The average beta to alpha cell ratio for the 3 groups was 15.24, 9.84 and 8.50, respectively. It is suggested that the iodide first became organically bound, and in this form was responsible for the action on the pancreas.—B. W. Simpson.

SHELLABARGER, C. J. and GODWIN, J. T. **Studies on the thyroidal uptake of astatine in the rat.** *J. Clin. Endocrinol.*, 1954, **14**, 1149-1160. [Brookhaven Nat. Lab., Div. Pathol., Med. Dept., Upton, Long Island, N.Y.]

Experiments were made to test the ability of the thyroid gland to concentrate the heavy radio-halogen element 85 (astatine, At) and to compare its effects with those of ^{131}I . In experiments with rats At was concentrated by the thyroid, but not to such an extent as ^{131}I . Thiouracil enhanced the uptake of At. In histological preparations of thyroid tissue, clusters of x-ray tracks were thought to represent clusters of At atoms.—B. W. Simpson.

2360

HAMILTON, J. G., DURBIN, P. W. and PARROTT, M. **The accumulation and destructive action of astatine²¹¹ (eka-iodine) in the thyroid gland of rats and monkeys.** *J. Clin. Endocrinol.*, 1954, **14**, 1161-1178. [Div. Med. Phys., Crocker Lab., Univ. California, Berkeley.]

Both ^{211}At and ^{131}I slowed growth in rats and monkeys. The early effect was ascribed to radiation injury and the late effect to lack of thyroid hormone. Myxoedema was observed in 4 of the monkeys injected with ^{211}At . In the rats, ^{131}I completely obliterated the thyroid gland, parathyroids and adjacent peritracheal tissues. ^{211}At had no such effect on parathyroids or peritracheal tissues, but did destroy thyroid tissue. A high incidence of neoplastic-looking mammary tumours was found in rats after injection of ^{211}At , and some pulmonary metastases occurred. The tumours were ascribed to endocrine changes, not to the direct action of radiation.—B. W. Simpson.

IRON AND COPPER

2361

OTTINGER, L. (Jr.), MILLS, W. B. and HAHN, P. F. **Iron absorption in premature and full-term infants.** *J. Pediat.*, 1954, **45**, 302-306. [Dept. Paediat., Sch. Med., Vanderbilt Univ., Nashville, Tenn.]

Vol. 25, No. 2

A single test dose of ^{59}Fe was given in the first week of life to 14 full-term and 10 premature infants. The iron was given as ferrous chloride and amounted to about 1.0 μg . elemental Fe. Two to 6 weeks later samples of blood were withdrawn. The blood of premature infants contained from 0.29 to 6.8, mean 2.8, per cent. of the test dose of ^{59}Fe and that of full-term infants contained from 0.4 to 8.2, mean 3.2, percent. No relation was found between the percentage of the test dose of Fe in the infant's blood and the Hb value of the mother's. F. C. Aitken.

2362

INGALLS, R. L. and JOHNSTON, F. A. **Iron from gastrointestinal sources excreted in the feces of human subjects.** *J. Nutrition*, 1954, **53**, 351-363. [New York State Coll. Home Econ., Cornell Univ., Ithaca.]

The subjects were 8 women 23 to 37 years of age, 145 to 168 cm. in height and 48.6 to 64.4 kg. in weight, but only 5 completed the experiment. Before each experimental period the subject avoided foods rich in Fe for 3 days; the experimental diet was then taken for 2 days of adjustment and 6 days of balance studies. In 3 such experimental periods the diets supplied about 1, 2 and 3 mg. Fe daily. The diet containing 1 mg. Fe consisted of 2 kg. milk daily and sugar dissolved in distilled water to meet the energy requirements. In the second period bread, apple sauce and peaches replaced part of the sugar, and in the third period egg and more peaches.

When the mean Fe intake was 1.03 mg. the mean excretion was 0.99 mg. The differences rose to 0.23 and 0.51 mg. when the intakes were 2.15 and 3.22 mg., and variability also increased. A regression was calculated of faecal excretion on intake, using also 3 pairs of values given by Johnston *et al.* (Abst. 886, Vol. 25) for women on intakes of 1.48 and 1.70 mg. Fe. The regression line when extended to zero intake gave a faecal excretion of 0.17 mg.

When it was assumed that gastro-intestinal Fe in the faeces is constant at all Fe intakes, and that the percentage absorbed at all the 3 low intakes of 1 to 3 mg. is nearly the same, the percentage absorbed was estimated to lie between 18 and 25 per cent. and the gastro-intestinal Fe output between 0.12 and 0.27 mg., which agrees with the estimate by the regression method.

The positive correlation between faecal dry weight and Fe output was highly significant except in 2 subjects given mineral oil.

- DICK, A. T. Preliminary observations on the effect of high intakes of molybdenum and of inorganic sulphate on blood copper and on fleece character in crossbred sheep. *Austral. Vet. J.*, 1954, 30, 196-202. [Div. Animal Health Prod., C.S.I.R.O., Animal Health Res. Lab., Parkville, Victoria.]

Four groups of 4 wether sheep received for 2 months a basal diet of chaffed oat hay 80 and wheat bran 20 per cent., with copper sulphate and ammonium molybdate to make their total daily intake 10 mg. Cu and 5 mg. Mo. Potassium sulphate was added to make the sulphate intakes of the 4 groups 1.1, 1.8, 3.1 and 5.7 g. daily. Blood samples were taken twice, with 2 days between, and after the second sample the 4 sheep on each sulphate intake received a different dose of Mo, 15, 30, 60 and 90 mg., respectively. Blood samples were taken after 24 hr., and the Mo drench and blood sampling were repeated for 3 days.

Blood Mo rose in all sheep during the days of high Mo intake, and at each level of sulphate the rise of blood Mo was related to the Mo intake. For each Mo intake the rise was less as sulphate intake increased. The rise in blood Cu for each sulphate intake also was greater the higher the Mo intake, and the effect of the Mo increased with higher sulphate intake.

In another experiment 3 sheep received a basal ration of equal parts by weight of chaffed alfalfa and oat hays. The mineral intakes were adjusted to 8 g. sulphate, 80 mg. Mo and 4.6 mg. Cu daily. Blood Cu rose within 3 days to about 0.125 mg. per 100 ml. Within 7 days the wool lost its crimp and became straight and steely (see Abst. 2669, Vol. 18). When after 6 weeks the Mo intake was reduced to 20 mg. daily the wool regained its crimp. The experiment was repeated in one sheep; in another, withdrawal of Mo from the diet had no effect on the fleece. The liver Cu values did not fall.

It is suggested that with high intakes of Mo and sulphate a large proportion of the circulating Cu is not physiologically available.—D. Duncan.

The difference in caries-producing effect between 2 synthetic diets rich in sucrose (see Abst. 957, Vol. 24) was considered to have possibly arisen from the presence of a small amount of Al in the Emory salt mixture and its absence from the Harvard one. Groups of Wistar rats were therefore given a synthetic diet of sucrose 64, casein 20, fat 8, extract of yeast and liver 4, and salt mixture 4 per cent., without added Al or with Al at levels of 0.16, 2 or 20 p.p.m. Experiments were made with normal rats and with rats desalivated at 120 days old; all were killed at 180 days old.

Desalivation increased both the number of lesions and their severity, but the differences produced by the variation in Al intake were small and not statistically significant. At these levels, too, the appetite and growth of the rats were unaffected.—D. Harvey.

WEIR, W. C. and RENDIG, V. V. **Serum inorganic sulfate sulfur as a measure of the sulfur intake of sheep.** *J. Nutrition*, 1954, **54**, 87-96. [Dept. Animal Indust., Univ. California, Davis.]

Yearling wethers received different quantities of sulphur and serum inorganic sulphate was estimated.

A daily intake of 1.7 to 2.3 g. S, of which almost half was from methionine added to the hay diet, gave serum values during 8 days of 2.2 to 3.9 mg. per 100 ml. This was followed by 10 days during which the intake was 1.0 to 1.5 g., derived from the same hay without methionine added. The serum S fell to just under 1.0 mg. per 100 ml. Finally the same sheep were fed on unsupplemented hay to appetite for 11 days. The daily S intake increased to 1.6 to 2.3 g., and serum sulphate S to about 2.7 mg. per 100 ml.

In a second experiment a semi-synthetic diet containing only 0.02 per cent. S was given with and without elemental S. Serum values fell to about 0.07 μ g. per 100 ml. on the unsupplemented diet providing 0.2 g. S daily, but rose rapidly to 2.9 to 4.1 μ g. per 100 ml. when elemental S was given in amounts from about 4.0 to 6.0 g. daily.

It is suggested that serum sulphate concentration is useful for detecting low S intake in sheep.

FRIBERG, U. and RINGERTZ, N. R. **Uptake of radiosulphate and radiophosphate in various tissues of normal and scorbutic guinea pigs.** *Exp. Cell. Res.*, 1954, **6**, 527-528. [Dept. Histol., Karolinska Inst., Stockholm.]

Young female guineapigs weighing about 200 g. were given a scorbutogenic diet with or without addition of ascorbic acid. Some deprived and non-deprived animals were given an injection of radioactive ^{35}S in Na_2SO_4 , and some were given radioactive ^{32}P as orthophosphate. They were killed 48 hr. later. With ^{35}S the radio-activity in counts per min. per mg. wet tissue of blood, liver, spleen, brain, kidney, skin, muscle and bone from scorbutic animals was only about one-third that in tissues from non-deprived animals. In cartilage the radio-activity was less, but not significantly so. With ^{32}P there was no significant difference except in bone, where the uptake was less by about one-third in the scorbutic animals.

Vol. 25, No. 2

It is concluded that the results probably, at least in part, reflect diminished formation of sulphomucopolysaccharides.—E. M. Hume.

2373

JETER, M. A. and DAVIS, G. K. **The effect of dietary molybdenum upon growth, hemoglobin, reproduction and lactation of rats.** *J. Nutrition*, 1954, **54**, 215-220. [Dept. Animal Husb., Florida Agric. Exp. Stat., Gainesville.]

Rats were given a synthetic diet with Cu at 2 levels and Mo at 2 or 4. With Cu at 20 p.p.m., Mo was either < 1 or 80 p.p.m. and with Cu at 5 p.p.m., Mo was < 1, 20, 80 or 140 p.p.m. Growth was studied from weaning to 11 weeks of age, and reproductive performance thereafter.

With the high Cu intake, Mo did not affect growth in rats of either sex; at 5 p.p.m. of Cu growth of males was retarded at all levels of Mo intake and more so as the levels rose, but in females no retardation of growth was seen until the Mo level reached 80 p.p.m. In contrast to findings reported with ruminants, Hb values provided no evidence that Mo produced anaemia in rats. Achromotrichia, sometimes with alopecia, appeared with 80 or 140 p.p.m. Mo, but it was not universal. At these levels reproduction in females was reduced by infertility which, from matings with females of proven fertility and from histological examination of testes, was shown to be in the males. At the higher levels loss of weight by the females per young rat nursed and lower weight of the young at weaning showed that lactation had been adversely affected.—D. Harvey.

2375

FEASTER, J. P., HANSARD, S. L., McCALL, J. T., SKIPPER, F. H. and DAVIS, G. K. **Absorption and tissue distribution of radiozinc in steers fed high-zinc rations.** *J. Animal Sci.*, 1954, **13**, 781-788. [Florida Agric. Exp. Stat., Gainesville.]

Of Zn given by mouth to growing steers about 70 per cent. appeared in faeces and 0.3 per cent. in urine. When it was administered by vein, about 20 per cent. was recovered in faeces and 0.25 per cent. in urine.

Radio-active Zn given 6 days before the steers were killed was retained chiefly in the soft tissue, particularly the pancreas, liver, pituitary, kidney and adrenals. Zn in the skeleton was distributed approximately according to the metabolic activity.

of bones or parts of bones; *i.e.*, cancellous bone retained more than compact bone.

Steers given zinc carbonate supplying 1000 p.p.m. Zn in the diet gave the same results as those given 50 p.p.m. Zn.—R. Hill.

2376

WOLFF, H. and RINGLEB, D. Histochemische Untersuchungen über das Inselzink. [*Histochemical studies of zinc in the islets of Langerhans.*] *Ztschr. ges. exp. Med.*, 1954, **124**, 236-256. [Med. Poliklin., Univ. Marburg a.d. Lahn.]

Zn was studied in the pancreas of several species of small animals after intravenous injection of dithione in aqueous solution.

Of 24 rabbits all showed a strongly positive reaction for Zn in the islet cells. Under high magnification the reaction was shown mostly by violet-stained intracellular granules distributed near capillaries, in both alpha and beta cells. In

20 rats the alpha cells were strongly positive, the beta cells lightly stained. In 12 guineapigs no Zn was detected in cells of either type. Normal dogs showed a high concentration in the beta cells but none in the alpha cells and alloxan-diabetic dogs showed no reaction.

Mice received the dithione intraperitoneally instead of by vein; the positive reaction for Zn was almost confined to beta cells.

The Zn content of alpha cells in rats fell during starvation and was small after 72 hr.; it was also reduced after insulin, in the compensatory hypoglycaemic phase after glucose injection, after adrenaline injection and after stimulation of sympathetic nerves, though intraperitoneal infusion of acetylcholine was without effect.

In rabbits the Zn content of the beta cells rose during starvation for 96 hr., and decreased somewhat after administration of glucose or adrenaline, though not after insulin.—D. Duncan.

ACID BASE EQUILIBRIUM

2377

VAN GOIDSSENHOVEN, G. M. T., GRAY, O. V., PRICE, A. V., and SANDERSON, P. H. The effect of prolonged administration of large doses of sodium bicarbonate in man. *Clin. Sci.*, 1954, **13**, 383-401. [Med. Unit, St. Mary's Hosp., London, W.2.]

Thirty-three patients with peptic ulcer were given up to 140 g. NaHCO₃ daily for 3 weeks without ill effect. There was no evidence of kidney damage except in one patient who developed persistent albuminuria. All showed marked alkalosis. Large quantities of Na were retained, and this was associated with a greatly expanded extracellular space. Two patients with pyloric stenosis are discussed separately because of their unusual response to alkali. Plasma CO₂ rose much higher than would have been expected in normal subjects, but blood urea was not much increased.—F. C. Aitken.

2378

LIPSKY, S. R., ALPER, B. J., RUBINI, M. E., VAN ECK, W. F. and GORDON, M. E. The effects of alkalosis upon ketone body production and carbohydrate metabolism in man. *J. Clin. Invest.*, 1954, **33**, 1269-1276. [Dept. Int. Med., Sch. Med., Yale Univ., New Haven, Conn.]

The effect of large infusions of sodium acetate or equimolar solutions of sodium bicarbonate was studied in normal and diabetic subjects. In normal subjects there was no appreciable change in blood sugar after acetate or bicarbonate. Blood ketones increased slightly but significantly after acetate but not after bicarbonate. In diabetes,

blood sugar decreased after acetate or bicarbonate; blood ketones increased significantly in mild diabetes after acetate and in severe diabetes after acetate or bicarbonate. In 2 diabetic subjects acetate caused depression of splanchnic glucose output and peripheral glucose concentration and increase of splanchnic ketone production and peripheral blood ketones.—F. C. Aitken.

2379

BONTING, S. L. The effect of a prolonged intake of phosphoric acid and citric acid in rats. *Thesis, Univ. Amsterdam*, 1952, pp. viii + 97.

The literature on regulation of acid base equilibrium and the effects of acid intake is reviewed: there are 170 references. The work was done because of the widespread use of phosphoric acid and citric acid in soft drinks.

Rats were fed to appetite on a basal diet containing, per cent., casein 6, dried whole milk 10, whole wheat flour 34.5, potato flour 33, groundnut oil 6.5, cod liver oil 0.5, linseed oil 0.5, brewer's yeast 5 and salt mixture 4. Phosphoric acid was added at 0.05, 0.15, 0.40 and 0.75 per cent. for some groups, and others received 0.15, 0.45 or 1.20 per cent. citric acid. Only the groups with the 2 highest intakes of phosphoric acid and the highest of citric acid were kept in the experiment after 6 months, and observations continued through 2 filial generations.

There was no harmful effect of even the highest intakes of either acid on growth in 3 generations, or on reproduction, or on the blood picture of the first 2 generations. No pathological change could be attributed to the acids. The incidence of

caries was the lowest ever recorded in the colony, but calcium was deposited in the dentine and the molar teeth of rats receiving phosphoric acid were very white. Dental attrition was greatest in rats receiving phosphoric acid. Two metabolism experiments were made, one with control periods at beginning and end and acid given for 8 weeks, the other comparing control rats with rats given acid for the preceding 8 months. P turnover was higher in both experiments in rats given phosphoric acid; P excretion in urine increased, but not that in faeces. There was a probable, but not significant, increase in Ca retention. Total N balance was unchanged, but phosphoric acid, though not citric, caused a considerable increase in ammonia excretion at the expense of urea. Total base

excretion was unchanged, but titratable acidity of the urine was increased and its pH was reduced by phosphoric acid. Serum inorganic P was raised by both acids. Serum Ca was less in rats receiving citric acid than in other groups. There was no acidosis even with the highest acid intake in the second generation after a year. There was no important change in liver weight or total P, K, Na or Cl content, or in the kidneys. Tests with ^{32}P indicated no change in the P metabolism of bone.

It is concluded that since in man the mechanisms involved in neutralisation and excretion of ingested acids resemble those in the rat, no ill effect is to be expected from prolonged consumption of beverages acidulated with phosphoric acid or citric acid.—D. Duncan.

METABOLISM OF WATER

2380

YAMAGUCHI, Y., ASANO, S., MATSUKI, S., HIWATARI, S., TANIDA, R., DOI, K. and KATO, E. The effect of muscular exercise on the body fluid balance. *Keio J. Med.*, 1953, 2, 49-58. [Dept. Int. Med., Sch. Med., Univ. Keio.]

Three healthy young men were maintained on a constant diet for 9 weeks, during the middle 3 of which they exercised continuously for 50 min. twice a day on a bicycle ergometer and received an additional 500 Cal. daily as fat and carbohydrate. Bodyweight, water intake and output, plasma volume and thiocyanate space were measured. It was concluded that body fluid to the extent of about 1 litre was retained, chiefly in extracellular space, during the period with exercise, and was excreted within a few days after the exercise ceased.

E. M. Hume.

2381

TENG, H. C., SHAPIRO, A. P. and GROLLMAN, A. Volume of the fluid compartments in human and experimental hypertension. *Metabolism*, 1954, 3, 405-411. [Dept. Int. Med., Southwestern Med. Sch. Univ. Texas, Dallas.]

Plasma volume, extracellular fluid volume and total body water were estimated in 20 hypertensive patients and 20 normal subjects of nearly similar age, height, weight and body conformation. Antipyrine space was estimated in 16 hypertensive and 12 normal dogs, total body water was estimated with antipyrine in 5 dogs before and after induction of hypertension, and deuterium oxide space in 5 male hypertensive dogs and 5 male control animals matched for size, weight and breed.

There was a significantly greater extracellular fluid volume in the 20 hypertensive patients, slightly but not significantly more total body water and no greater plasma volume than in the normal subjects. Significant increases in total body water

occurred in dogs after induction of hypertension; in the other groups of dogs studied the difference was not significant.—G. F. Garton.

2382

LINAZASORO, J. M., JIMÉNEZ DÍAZ, C. and CASTRO MENDOZA, H. El riñón y la regulación de la sed. [The kidney and the regulation of thirst.] *Rev. clín. española*, 1954, 54, 138-141. [Sección Bioquím., Inst. Invest. Med., Madrid.] English, German and French summaries.

In nephrectomised animals thirst is not in proportion to their water requirement, but thirst occurs normally in nephrectomised animals given an injection of active renal extract after operation. For 20 normal fasting rats the average daily intake of water for 2 days was 8.62 ml., for 24 nephrectomised animals it was only 5.04 ml., and 25 rats given renal extract after operation drank 7.08 ml.

It is suggested that the kidney contributes to osmotic regulation by producing a thirst hormone. M. B. Richards.

2383

CRAMPTON, E. W. and LLOYD, L. E. The effect of water restriction on the food intake and food efficiency of growing rats. *J. Nutrition*, 1954, 54, 221-224. [Dept. Nutrit., Macdonald Coll., McGill Univ., Que.]

In 4 tests 164 rats aged from 4 to 8 weeks were fed to appetite on stock diet. They were paired and one of each pair was allowed half the water voluntarily taken by the other.

The 50 per cent. restriction of water intake led to an average reduction of 27 per cent. in food intake and 51 per cent. in weight gain, and the ratio of gain to food intake was reduced by 30 per cent.—D. Duncan.

TEDESCHI, G. G. Eliminazione urinaria della coarbossilasi e degli acidi lattoflavinfosforico, serinfosforico, treoninfosforico e creatinfosforico. [Excretion in the urine of coarboxylase and of the phosphates of riboflavin, serine, threonine and creatine.] *Quad. Nutrizione*, 1952, 12, 486-493. [Ist. Fisiol. Gen., Univ. Rome.] French, English and German summaries.

Experiments were made on groups of 3 rats weighing about 100 g. and maintained on stock diet, but allowed only water for 24 hr. before each test. The substances to be studied were injected subcutaneously. Urine was then collected for an hour and the bladder was emptied at the end. The composition of the urine was studied by paper chromatography.

All the phosphorylated compounds given, coarboxylase and riboflavin, serine, threonine and creatine phosphates, were excreted at least partly unchanged.—D. Duncan.

SIRNES, T. B. Voluntary consumption of alcohol in rats with cirrhosis of the liver. A preliminary report. *Quart. J. Studies Alcohol*, 1953, 14, 3-18. [Dept. Pharmacol., Univ. Oslo.]

Twenty rats, 3 months old, maintained on stock diet, were injected twice a week with 0.2 ml. carbon tetrachloride. Some were killed and histological changes characteristic of cirrhosis were found in the liver. Injection with CCl_4 was stopped and, 3 weeks later, the rats were given the choice of water or 20 per cent. ethanol solution to drink. The amounts consumed were measured daily for from 36 to 55 days. Some rats died and others were killed. The presence of cirrhosis was confirmed at autopsy. Rats without experimental cirrhosis were given alcohol in the same way for comparison. For 10 rats with confirmed cirrhosis the mean daily consumption was 0.82 ml. absolute alcohol per 100 g. bodyweight, compared with 0.19 for normal rats of the same age.

Estimations of alcohol in the blood and urine showed that alcohol could be oxidised rapidly by cirrhotic rats.—E. M. Hume.

VITALE, J. J., NAY, J. and HEGSTED, D. M. Partial starvation and alcohol metabolism. An example of adaptation to undernutrition. *J. Nutrition*, 1954, 53, 533-541. [Dept. Nutrit., Harvard Sch. Pub. Health, Boston, Mass.]

Adult rats were given to appetite a standard purified diet containing 20 per cent. protein;

intake was on the average 12 to 14 g. per rat daily. Six similar rats were given 10 g. per rat daily. When no loss of weight occurred in 5 days the intake of both groups was reduced to 8 g., then to 6 g. daily. Another group of rats which received food to appetite was changed immediately to an intake of 5 g. daily. At different times animals from each group were injected with 20 per cent. ethanol containing ethanol- $1\text{-}^{14}\text{C}$, at 2 g. per kg. bodyweight; the ability to oxidise the ethanol was estimated from the excretion of $^{14}\text{C}_2\text{O}$ in the next 6 hr.

Oxidation of ethanol became slower as the rats lost weight; normal rats metabolised 80 per cent. of the injected ethanol in 6 hr., a bodyweight loss of 10 g. produced a 12 per cent. decrease in the amount of ethanol oxidised and there was a 40 per cent. decrease when the animals had lost 40 g. bodyweight. When weight became stabilised on the lower food intakes the ability to oxidise ethanol returned to normal. When the rate of weight loss was increased by more severe restriction the results were similar but more rapid. In vitamin- B_1 -deficient rats the amount of ethanol oxidised fell as the deficiency progressed, but, as bodyweight never became stabilised, the fall in ethanol oxidation continued until death.

G. F. Garton.

VITALE, J. J., HEGSTED, D. M., McGRATH, H., GRABLE, E. and ZAMCHECK, N. The effect of acetate, pyruvate, and glucose on alcohol metabolism. *J. Biol. Chem.*, 1954, 210, 753-759. [Dept. Nutrit., Harvard Sch. Pub. Health, Boston, Mass.]

The oxidation of injected ethanol- $1\text{-}^{14}\text{C}$ as measured by expired radio-active CO_2 in rats was decreased by about half by injection of pyruvate or acetate; the disappearance of alcohol from the blood was delayed. In rats deficient in vitamin B_1 the inhibition of oxidation of alcohol produced by pyruvate was less.

The alcohol was presumably oxidised to acetaldehyde by alcohol dehydrogenase, which requires diphosphopyridine nucleotide (DPN) as a coenzyme, and then further to acetate, which is oxidised in the tricarboxylic acid cycle along with pyruvate. The inhibition may be due to competition for DPN, which is also essential in the tricarboxylic acid cycle. This view was supported by the observation that nicotinamide, which is the active constituent in the DPN molecule, when given in large amounts also prevented the inhibition.

Sucrose administered by mouth raised the blood sugar and decreased the rate of disappearance of alcohol in human subjects.—A. Hepburn.

- WARMING-LARSEN, A. Ketone metabolism in obesity. 2. *Acta med. scand.*, 1954, **150**, 47-52. [Med. Afrd., Blegdamshosp., Copenhagen.]

For part 1 see Title 3366, Vol. 18.

Blood ketones were studied during fasting in 42 obese persons, including the 16 described in the earlier paper. The controls were the same 25 subjects as before.

At the beginning of starvation blood ketone concentrations, expressed as β -hydroxybutyric acid, did not differ significantly between obese and normal subjects, but on the 4th morning of fasting the values in the obese persons showed a much wider range of variation than in the normal. No endocrine disturbance was found in these patients. The metabolic change involved is discussed.

- HOVE, E. L., COPELAND, D. H. and SALMON, W. D. Choline deficiency in the rabbit. *J. Nutrition*, 1954, **53**, 377-389. [Dept. Animal Husb., Agric. Exp. Stat., Alabama Polytech. Inst., Auburn.]

Weanling rabbits fed on a basal diet deficient in choline gained a little weight and then remained about the same or else lost weight. They lost their hair, and death ensued within 66 to 217 days. There was moderate or severe nodular cirrhosis of the liver and extensive tubular necrosis of the kidneys. Two adult rabbits fed on the same diet immediately began to lose weight and died after 45 and 53 days with severely cirrhotic and fatty livers.

The addition of choline to make up 0.13 per cent. of the diet prevented these disorders and maintained growth. There was no further increase in growth rate with 0.20 per cent. choline, and 0.05 per cent. was insufficient. Methionine could replace choline to a certain extent, and with monomethylethanolamine, but not ethanolamine, there was immediate growth. Vitamin B₁₂ with folic acid appeared to improve the utilisation of methionine, but did not spare suboptimum levels of choline or promote the methylation of monomethylaminoethanol by methionine to form choline.

Moderate anaemia developed and the plasma was bright golden yellow after 70 days. There was no jaundice, and a test for bile pigments was

only slightly positive at a much later stage of choline deficiency. A substance, apparently porphobilinogen, a proposed intermediate in Hb formation, was found in the urine. Methionine or suboptimum levels of choline partly prevented the anaemia. Vitamin B₁₂ with folic acid produced no further improvement.—A. Hepburn.

2391

- HOVE, E. L. and COPELAND, D. H. Progressive muscular dystrophy in rabbits as a result of chronic choline deficiency. *J. Nutrition*, 1954, **53**, 391-405. [Dept. Animal Husb., Agric. Exp. Stat., Alabama Polytech. Inst., Auburn.]

Rabbits fed on a diet deficient in choline developed progressive muscular dystrophy after 70 to 100 days. Muscular weakness occurred especially in the hind legs, with hyaline degeneration. Urinary creatine progressively increased to more than 40 mg. per kg. bodyweight daily, and urinary creatinine gradually decreased, both effects characteristic of human dystrophies. Choline rapidly effected a cure.

Since all the rabbits received 10 mg. α -tocopheryl acetate daily and had normal plasma tocopherol values and tissues rich in tocopherol, vitamin E deficiency was not the cause of the dystrophy.

The effect of a single dose of α -tocopheryl acetate in vitamin-E-deficient rabbits was prolonged when acetylcholine chloride, 0.1 or 1.0 per cent., was added to the diet.—A. Hepburn.

- MIRONE, L. Effect of choline-deficient diets on growth, reproduction and mortality of mice. *Amer. J. Physiol.*, 1954, **179**, 49-52. [Dept. Nutrit., Univ. Georgia, Athens.]

Weanling mice fed on a diet with little or no choline grew normally during the first 9 weeks. Blood red and white cell counts and Hb were not significantly different after 3 and 7 months. The conception rate and viability of the young were lower than in mice fed on stock diet. Most of the litters from mice fed to appetite on the basal diet containing 50 mg. choline chloride per 100 g. died during the first 4 days. Survival was increased by the addition of 5 μ g. vitamin B₁₂, but death occurred before weaning. In the absence of choline vitamin B₁₂ was not beneficial. Mortality in adult mice was highest during the third and fourth months of life, and death at parturition was due to incomplete expulsion of the foetus accompanied by profuse bleeding. Loss of contractility of the uterus was considered a possible cause.

CANDELA, J. L. R., VALLADARES, Y. and CANDELA, R. R. Mecanismo patogénico de la disminución de la tolerancia a los hidrocarbonados en la enfermedad de Cushing. [Pathogenesis of the reduced tolerance to carbohydrates in Cushing's syndrome.] *Medicamenta*, 1954, 22, 295-298. [Cat. Patol. Gen., Madrid.]

The method is described by Candela *et al.* (*Rev. Ibér. Endocrinol.*, in the press). The "insulin effect" of plasma was estimated from the glucose consumption and glycogen formation of isolated diaphragm muscle from rats. The plasma of 4 subjects with Cushing's syndrome had the same "insulin effect" as that from 4 normal subjects, but when extra insulin was added the plasma from the 4 patients inhibited the activity of the insulin. It is suggested that there is a synergy between glucagon and insulin.—D. Duncan.

KHESIN, R. B. Vkluychenie mechenykh aminokislot v syvorotochyi al'bumin kletok pecheni krysa. [Inclusion of labelled amino-acids into the serum albumin of the cells of rat liver.] *Biokhimiya*, 1954, 19, 304-312. [Inst. Biol. Khim., Akad. Med. Nauk SSSR, Moscow.]

The rate of inclusion of tracer amino-acids into the serum albumin component of structural entities of the liver cell was studied by comparing the curves of radio-activity of the free amino-acid fraction of liver cells with changes in radio-activity of the albumin of these structural entities within the cells. Live male rats were injected and killed, and liver slices were homogenised and centrifuged at different speeds to separate intracellular structures. The precipitates were washed with butanol and/or water to extract the albumin. After subcutaneous injection of ^{35}S -methionine and

N.A. and R., April 1955

^{14}C -tyrosine the labelled amino-acids were incorporated most quickly in that fraction of serum albumin "tightly bound" in the large cytoplasmic granules. The radio-activity of the "tightly bound" moiety in the large granules was dependent on that of the free acid fraction. It was concluded, from comparison of changes in radio-activity of the albumin of different cell fractions, that albumin formed in the large granules is transferred to other cell structures, e.g., microsomes, not as a result of mechanical disintegration of these granules, but by an active process necessitating aerobic conditions.

The serum albumin liberated from rat liver exists in large granules similar to the secretory granules of the pancreas.—D. W. Taylor.

STERN, I. and SHAPIRO, B. **The transport of lipids into adipose tissue.** *Metabolism*, 1954, **3**, 539-543. [Dept. Biochem., Hadassah Med. Sch., Hebrew Univ., Jerusalem.]

Fat-depleted adipose tissue from starving male rats was incubated in air at 38° C. in human serum, rat serum or lipid suspensions containing triolein, egg lecithin, sorbitan monolaurate, sorbitan monopalmitate, sorbitan mono-oleate, sodium oleate or ^{14}C -labelled sodium stearate; in some experiments 0.05 *M* NaF was added to the incubation medium. Samples of the medium were removed after incubation for 7 min., 2 hr. or 4 hr. for analysis of the lipid components; the first sample represented the initial values.

When adipose tissue was incubated in serum the total fatty acid content of the serum decreased; no decrease was observed in the phospholipid and cholesteryl ester fractions. Fatty acids were absorbed from emulsions of triolein and of the sorbitan esters; absorption was inhibited by NaF. Egg lecithin was not absorbed. The fatty acids

of the soap emulsions were taken up by the tissue and absorption was not inhibited by NaF. Good recovery of absorbed fatty acids (in a combined form) from the incubated tissue was obtained.

It is concluded that uptake of fatty acids from serum into adipose tissue probably occurs as a result of enzymic cleavage of the ester linkages of triglycerides and other neutral esters.

EVANS, J. D., RIEMENSCHNEIDER, R. W. and HERB, S. F. **Fat composition and *in vitro* oxygen consumption of marrow from fed and fasted rabbits.** *Arch. Biochem. Biophys.*, 1954, **53**, 157-166. [Dept. Physiol., Sch. Med., Temple Univ., Philadelphia, Pa.]

Six young male rabbits were given no food for 4 to 11 days, during which they lost on the average 28 per cent. of their original bodyweight; water was unlimited. Bone marrow from the long bones was pooled for study of oxygen consumption in a Warburg apparatus and estimation of Fe and of polyunsaturated fatty acids by alkali-isomerisation. Another 6 control rabbits were given a stock diet and fresh vegetables.

Unsaturated fatty acids comprised 62 per cent. of the total marrow fat of both groups, though the linoleic acid contents were different, accounting for 33 per cent. of the fat of the control group and 25 per cent. in the fasted group. The absolute amounts of all fatty acids decreased during starvation, and the relative amounts of linoleic and linolenic acids decreased while the percentages of arachidonic, pentaenoic and oleic acids increased. The rate of oxygen consumption was not related to the concentration or fatty acid composition of the marrow fat. It is concluded that the polyunsaturated fatty acids of marrow fat are not metabolised *in situ*.—G. A. Garton.

HANEL, H. K., CHRISTENSEN, F. and DAM, H. **Alimentary production of gallstones in hamsters. 4. Cholesterol synthesis *in vitro* from 2-C- 14 -acetate in the liver of hamsters with**

and without gallstones. 5. Cholesterol synthesis from 2-C-14-acetate by the liver *in vivo*. *Acta pathol. microbiol. scand.*, 1954, **35**, 237-239; 423-425. [Dept. Biochem. Nutrit., Polytech. Inst., Copenhagen.]

For part 3, see Abst. 1033, Vol. 25.

4. Liver slices were prepared from male hamsters which had been fed on normal diets or a diet which gave rise to gallstones (Abst. 4874, Vol. 23). The slices were incubated in the presence of ^{14}C -labelled acetate for 3 hr. at 37.5°C . in an atmosphere of oxygen with 5 vol. per cent. CO_2 . After saponification, cholesterol was isolated as the digitonide and its radio-activity was measured.

The results showed no significant difference in the rate of cholesterol synthesis in the liver tissue of hamsters with and without gallstones.

5. Male hamsters were reared for about 2 months on diets similar to those used in the study just reported. They were then given ^{14}C -labelled acetate by subcutaneous injection and liver slices were prepared and examined as described above. Again, the rates of liver cholesterol synthesis were not significantly different in the animals given the normal and the lithogenic diets.—G. A. Garton.

2407

PILGEMAN, L. O. and GREENBERG, D. M. Susceptibility to experimental atherosclerosis and the methylation of ethanolamine-1, 2- C^{14} to phosphatidyl choline. *Science*, 1954, **120**, 760-761. [Dept. Physiol. Chem., Sch. Med., Univ. California, Berkeley.]

The formation of lecithin from free ethanolamine was studied in liver slices from rats, guinea-pigs and chickens. The total liver capacity for lecithin formation in the guinea-pig was 3.8 per cent. and in the chicken 3.1 per cent. of its value in the rat, and the capacity relative to bodyweight was even less in the 2 species first named. The higher activity of rat liver was seen also when $^{14}\text{CH}_3$ -methionine was used as methyl donor for unlabelled ethanolamine.

The findings are discussed in relation to the susceptibility of guinea-pigs and chickens to atherosclerosis, and it is suggested that this may be related to a low capacity for phospholipin formation.—D. Duncan.

SOBEL, A. E. and BURGER, M. Calcification. 14. Investigation of the role of chondroitin sulfate in the calcifying mechanism.

HEIMER, C. B., MASLOW, H., SOBEL, A. E. and GRAYZEL, D. M. 15. *In vitro* calcification of rachitic bone cartilage of thyroparathyroidectomized rats. *Proc. Soc. Exp. Biol. Med.*, 1954, **87**, 7-13; 13-16. [Dept. Biochem., Jewish Hosp., Brooklyn, N.Y.]

14. Calcification *in vitro* of bone sections from rachitic rats was inhibited by toluidine blue or by protamine, but inhibition was less when Ca was present as well, and could be reversed if the sections were treated with Ca after toluidine blue or protamine.

Metachromasia, but not calcification, was prevented by high concentrations of Ca ions, and calcification, but not metachromasia, was prevented by protein denaturants.

When rachitic bone was shaken with a Ca solution and afterwards with a phosphate solution calcification took place, but not when the phosphate treatment preceded the Ca treatment. It is suggested that an initial part of the process of calcification is the formation of a Ca compound with the matrix.

Complexes of collagen and chondroitin sulphate were prepared and treated in the same way as the rachitic bone sections. Metachromatic staining and calcification took place and were inhibited in the complexes under conditions similar to those affecting rachitic bone.

It is concluded that complexes similar to those prepared in these experiments are involved in calcification.

15. Rickets was produced as readily in thyroparathyroidectomized rats as in controls by a diet high in Ca and low in both P and vitamin D. Calcification was similar in bone sections from thyroparathyroidectomized and from control rats.

ENGELFELDT, B. and HJERTQVIST, S. O. Biophysical studies on bone tissue. 10. The *in vivo* and *in vitro* uptake of radioactive isotopes and ionic exchange reactions in bone tissue. *Acta pathol. microbiol. scand.*, 1954, **35**, 205-216. [Dept. Phys. Cell Res., Karolinska Inst., Stockholm.]

See also Abst. 796, Vol. 24.

By means of autoradiography and microradiography the uptakes of ^{32}P , ^{45}Ca and ^{35}S were studied *in vivo* and *in vitro* in the bone tissue of dogs. All the isotopes were taken up by the newly laid down, poorly mineralised areas of bone tissue, but S uptake differs from that of P and Ca. Part of the sulphate goes to the organic and part to the inorganic phase, whereas ^{32}P and ^{45}Ca both go to the inorganic phase. All 3 isotopes, both *in vivo* and *in vitro*, show exchange reactions with ions in the surrounding fluid. ^{45}Ca seems to be more firmly fixed to the bone tissue than ^{32}P , and ^{35}S less.

The more pronounced ionic exchange in the poorly mineralised areas may be due to the smaller size and hence greater surface area of the crystallites or, since they are presumably still growing, to the presence of many imperfect zones in their crystal lattices.—M. B. Richards.

¹³¹I was injected intraperitoneally into adult rats 18 hr. before they were killed. Injections of thyroxine and thyroid-stimulating hormone (TSH) were given to some. Thyroids were removed quickly and incubated at 37°C. \pm 1° for 4 hr. From the results of 6 experiments it was concluded that thyroxine *in vitro* had not the inhibitory effect on thyroid activity which it exerts *in vivo*. There was no evidence from the studies *in vitro* of any influence of thyroxine on the release of inorganic or organic I from thyroid tissue. The primary effect of TSH *in vitro* was to release thyroid hormone from the gland and to increase the content of inorganic and organic ¹³¹I within the gland. The effect of thiocyanate *in vitro* was to inhibit the uptake of I by the gland.

- BITTNER, J. J. Mammary cancer in mice observed in different laboratories and during the war period. *J. Nat. Cancer Inst.*, 1954, **15**, 359-366. [Div. Cancer Biol., Dept. Physiol., Med. Sch., Univ. Minnesota, Minneapolis.]

Changes in the incidence and age of incidence of spontaneous mammary cancer in 2 inbred strains of mice moved from Bar Harbor, Maine to Minnesota in 1942 and fed throughout on Purina fox chow and tap water are ascribed to war and post-war changes in the composition of the chow. The manufacturers state that during the war the content of animal products and hence of animal-protein factor and vitamin B₁₂ was reduced. It is suggested that the physiological effects of the hormonal patterns were thereby altered, though not sufficiently to affect breeding behaviour.

- BABSON, A. L. and WINNICK, T. Protein transfer in tumor-bearing rats. *Cancer Res.*, 1954, **14**, 606-611. [Radiation Res. Lab., Coll. Med., State Univ. Iowa, Iowa City.]

In young adult rats bearing Walker carcinomas in both hind legs and killed 8 days after transplantation, when the combined weight of both tumours was from 12 to 23 g., free and combined amino-acid concentrations were higher in the liver than in normal rats, and combined amino-acids were higher in muscle, though free and total amino-acids were less. The tumours had high concentrations of bound and free amino-acids.

Plasma protein containing leucine labelled with ¹⁴C appeared to be incorporated into the tumours without much release of free leucine, and to be more readily utilised than free leucine. A labelled tumour when transplanted released labelled amino-acids into the host's tissues.—D. Duncan.

- SASSENATH, E. N. and GREENBERG, D. M. (with KEFFER, L. S. and SILLS, R. A.) Tumor host relationships. 1. Effects on free amino acid concentrations of certain tissues. *Cancer Res.*, 1954, **14**, 563-569. [Dept. Physiol. Chem., Sch. Med., Univ. California, Berkeley.]

Amino-acids were estimated microbiologically and by ion exchange column chromatography in deproteinised filtrates of blood, liver and skeletal muscle from normal and tumour-bearing adult rats. The latter were killed 7 to 9 days after transplantation of Walker carcinoma 256, when the tumours weighed from 2 to 5 g.

No characteristic pattern of free amino-acid concentrations was found in tumour-bearing rats. The most evident changes, increases in alanine and glutamic acid and decrease in glycine, are

considered to be related to increased energy demands in the organism. The difficulties of the microbiological method are discussed.—D. Duncan.

HOCH-LIGETI, C. Effect of prolonged feeding of methyleholanthrene to rats kept on a low

protein diet. *Cancer Res.*, 1954, 14, 749-752. [Dept. Pathol., Med. Sch., Univ. Virginia, Charlottesville.]

Sixty male and 40 female rats were given a diet of vitamin-free casein 7, sugar 6.5, maize starch 56, cellulose 12, lard 6.5, vegetable oil 8, salt mixture 3 and cod liver oil 1 per cent., supplemented with α -tocopherol and vitamins of the B group. To the diet of 40 males and 20 females was added 10 mg. methyleholanthrene per 100 g. food; after 22 weeks 10 males and 10 females from this group were transferred to the basal diet without methyleholanthrene. After 50 weeks rats were killed at intervals and organs were removed for histological examination.

The average growth for all rats was 1 g. weekly. Mortality among rats receiving methyleholanthrene was very high during the first 4 months, when 12 males and 7 females died as compared with 1 female and 2 males in the control group; after this time mortality was low in both groups. There was no appreciable difference in lesions between rats given methyleholanthrene for 5 months and those given methyleholanthrene during the whole experiment. In the livers of rats on the basal diet fatty changes and cirrhosis developed; in rats which received methyleholanthrene the cirrhosis was more severe. Male rats were more prone to liver damage than females. Ulcers, squamous hyperlasia and papillomata developed in the stomachs of all the rats, but were more pronounced in those which received methyleholanthrene.—G. F. Garton.

WEGMAN, M. E. Weight at birth and survival of the newborn. *Pediatrics*, 1954, 14, 396-400. [Washington, D.C.]

These extracts from Shapiro and Unger, "Weight at birth and its effect on survival of the newborn in the United States, early 1950" (*Vital Statistics Spec. Reps., Selected Studies* 39 (1), July 23, 1954) include a table and graphs of the distribution of birthweights of white and non-white infants born in the United States in the first quarter of 1950, with the corresponding neonatal mortality rates. Although it has been shown (Abst. 1455, Vol. 13) that for given birthweight negro infants are more mature than white, the neonatal mortality rates for the lower birthweights, i.e., the premature infants, are similar, and for the higher birthweights the rate is higher for non-whites. The conclusion is that the latter do not receive the same care.

The data also demonstrate the poorer chance of survival of the "overweight" infant.

MIETTINEN, M. On triplets and quadruplets in Finland. *Acta paediat.*, 1954, 43, Suppl. 99, pp. 103; *Acta paediat.*, 1954, 43, 493-496. [Child. Clin., Univ. Turku.]

This detailed survey is based on 603 sets of triplets and 18 sets of quadruplets, out of 633 and 20 sets born in Finland between 1905 and 1952. Triplet births were significantly more frequent in rural areas than in towns; about 68 per cent. of the parents were farmers or farm workers, many of them living under poor social conditions. Heredity played a considerable part. Multiple births were associated with increasing age and parity. The stillbirth rate for triplets was 12.60 ± 0.8 per cent., between 4 and 5 times that for all births

N.A. and R., April 1955

in Finland in the period. Of 791 triplet infants born between 1931 and 1952, 84.3 ± 1.3 per cent. had birthweights below 2500 g., and the lower the birthweight, the greater the mortality. During the last 50 years general infantile mortality in Finland has fallen from 12.28 ± 0.03 to 3.36 ± 0.04 per cent., but that of triplets has fallen much less and nearly half die in the first year. There was evidence of mental retardation in nearly 7 per cent. of 469 surviving triplets, but no connection with birthweight was found.—W. M. Deans.

LANGLOIS, M., RICHARD, M. and IASELLO, E. Contribution à l'étude de la fluctuation pondérale des premiers jours chez le nouveau-né normal. [Fluctuations in weight of the normal newborn infant in the first days of life.] *Laval méd.*, 1954, 19, 479-496. [Maternity and Child Welfare Service, Laval Univ., Quebec.]

A survey was made from birth of 86 infants of multiparous mothers, in 1953. The children were classified according to sex and to diet, breast milk or pasteurised cow's milk, whole or skimmed. No relation was found between the mean daily intake of energy or liquids and the loss and recovery of weight in the first few days of life. It was concluded that fluctuations of weight in the first few days depend much more on changes in fluid content than on amount of fat deposited, and on prenatal or constitutional influences more than on diet.

JORGE JANZ, G. Contribuição para o estudo do estado de nutrição da população de S. Tomé. [State of nutrition of the population of São Tomé.] 2. Pesos e alturas das crianças em idade escolar. [2. Weight and height of children of school age.] 3. O peso à nascença de crianças nascidas em S. Tomé. [3. Birth-weight of children born on São Tomé.] *An. Inst. Med. trop., Lisbon*, 1953, 10, 1515-1525; 1527-1533. English summary.

2. Measurements of height and weight were made on 920 children of São Tomé aged from 7 to 17 years, and regression equations were calculated showing the relations of weight to age and weight to height for black children and for those of mixed race of both sexes. The children of São Tomé were much inferior both in weight and height to what is regarded as normal in the white race, but similar to what is found in undernourished European children. There was no significant difference between the 4 groups considered in the average weights and heights.

3. A study was made of the birthweights of children of natives of São Tomé and of imported workers for the years 1949-1951. The average weight for boys was 2978 g. and for girls 2765 g., which gives an average weight for the 2 sexes of 2871 g. or 13 per cent. below the normal for European infants. Of the 625 infants studied 82.5 per cent. weighed at birth less than 3300 g. No difference was found between the children of natives of São Tomé and those of workers coming from Angola, Mozambique or Cape Verde.

SUTOW, W. W., TERASAKI, T. and OHWADA, K. Comparison of skeletal maturation with dental status in Japanese children. *Pediatrics*, 1954, 14, 327-333. [Dept. Paediat., Atomic Bomb Casualty Commission, Hiroshima.] Spanish summary.

Japanese children free from disease had X-ray photographs taken of their left hands and wrists and the numbers of the permanent teeth were recorded. There were 678 boys and 682 girls of ages from 6 to 14 years. The degree of skeletal maturation was assessed by the system of Greulich and Pyle ("Radiographic Atlas of Skeletal Development of the Hand and Wrist", Stanford Univ. Press, 1950) and the subjects were arranged in order of increasing maturity for each year of age. By dividing the series into 2 the categories designated as above or below average were obtained.

At each age girls had more permanent teeth than boys and children who were more advanced skeletally had more teeth than those less advanced.

For the sexes at individual ages consistent differences were not found. It is concluded that more mature skeletal development is associated with more mature dental status and that the data emphasise that investigations of this kind should not be limited to one or two age groups.

ELLIS, F. G. and JOSEPH, J. Time appearance of the centres of ossification of the fibular epiphyses. *J. Anat.*, 1954, **88**, 533-536.

[Dept. Anat., Guy's Hosp. Med. Sch., London.]

The times of ossification of the epiphyses of the fibula were studied in the rabbit, guinea-pig, cat, pig and kangaroo. In all species the centre of ossification for the distal appears earlier than that for the proximal end. In this respect the human fibula, although different from other human long bones, agrees with the fibulae of other mammals. The pattern is not related to any set of mechanical conditions existing in the human skeleton.

BURWELL, C. S. Circulatory adjustments to pregnancy. *Bull. Johns Hopkins Hosp.*, 1954, **95**, 115-129. [Dept. Med., Harvard Med. Sch., Boston, Mass.]

Some research is reported in this lecture and there is a review of recent literature.

Oxygen consumption, "under scrupulous basal conditions", amounts at a maximum to about 20 per cent. above the non-pregnant level; 70 to 80 per cent. of this increase is accounted for by the uterus and its contents, which consume about 5 to 7 ml. per kg. per min.

The heart rate rises to a maximum at about the thirtieth week of pregnancy and then declines towards term. At its height it is on the average about 10 beats per min. above non-pregnant levels. The systolic blood pressure remains relatively stable throughout pregnancy, but there is a slight fall in diastolic pressure. The maximum pulse pressure coincides with the time of maximum pulse rate.

There is a considerable increase in the cardiac output in pregnancy, amounting, at its maximum about the thirtieth week, to 40 to 50 per cent. above the non-pregnant level, after which it declines to term. The increase is not related to foetal weight or to the mother's total oxygen consumption, "it increases out of proportion to both". The maternal arterio-venous difference in oxygen saturation is therefore diminished. The main recipient of the increased cardiac output is the pregnant uterus and its contents. The uterine minute blood flow is about 500 ml. in women with a single foetus at term. There is no increased blood flow to the maternal liver, kidneys or brain, but a substantial increase in the flow to the hands has been demonstrated; this may play a part in heat elimination.

The blood volume rises in pregnancy until about the thirty-second week and then declines quite rapidly towards term, although the total body water continues to rise until the end of pregnancy. There is no substantial evidence where the increased blood volume is to be found. Much of it is in the uterine and placental circulation, but it is thought that the legs may store some, since the venous pressure in the legs of recumbent women is some 10 to 15 cm. water above normal. There may also be an increased pulmonary blood volume; the

N.A. and R., April 1955

lung in pregnancy is in a relatively expiratory position and there is a reduced expiratory reserve volume although vital capacity is maintained. Some observations on the heart rate during labour are included.—F. E. Hytten.

CAMPLING, J. D. and NIXON, D. A. **The inositol content of foetal blood and foetal fluids.** *J. Physiol.*, 1954, **126**, 71–80. [Dept. Physiol., St. Mary's Hosp. Med. Sch., London.]

Samples of human maternal and foetal blood and amniotic fluid were taken at parturition or during therapeutic abortion. Samples of allantoic fluid were also taken at several stages of pregnancy from sheep, cats, goats, rabbits and monkeys. The concentration of *meso*-inositol estimated microbiologically was unaltered by pregnancy; in foetal blood it was much greater, but bore no relation to that in maternal blood. The inositol concentration in blood from newborn kittens and rabbits fell to the maternal level in 14 days.

Amniotic fluid contained more inositol than maternal blood and less than foetal blood in man, sheep, monkey, cat and goat. Two of the 3 samples obtained during therapeutic abortion contained considerably more inositol than the foetal blood at normal parturition. Except in the sheep, the inositol concentration in the allantoic fluid was much greater than in foetal blood, especially in the rabbit.

Raising inositol in maternal blood did not significantly affect the concentration in the foetus, and raising the inositol concentration in the foetus only slightly affected that in the maternal blood of the ewe. Hence the placenta was considered impermeable to inositol transfer in one direction and in the other transfer was negligible. The substitution of a pump for the foetus and the circulation of maternal blood showed that inositol was not synthesised in the placenta.—A. Hepburn.

HEYDE, W. Beitrag zum Glucuronsäurestoffwechsel in der Schwangerschaft und im Wochenbett. [Glucuronic acid metabolism in pregnancy and the puerperium.] *Arch. Gynäkol.*, 1954–55, **185**, 1–18. [Frauenklin., Univ. Hamburg, Eppendorf.]

During the second half of pregnancy urinary excretion of glucuronic acid is distinctly higher than at other times, with excretory peaks at intervals of 30 days. A further increase in excretion occurs for several days before, and ends 24 hr. after, parturition. The increased glucuronic acid excretion is probably connected with increased hormone excretion in the urine. After parturition, urinary excretion of glucuronic acid is frequently below normal. The glucuronic acid content of the

amniotic fluid was of the same order as that of the serum. Experiments are described on the effect of administering glucuronic acid intravenously or by mouth.—M. B. Richards.

2437

HEYDE, W. Das Verhalten der Serumpolysaccharide ante und post partum. [Behaviour of serum polysaccharides before and after parturition.] *Arch. Gynäkol.*, 1954–55, **185**, 128–139. [Frauenklin., Univ. Hamburg, Eppendorf.]

For 20 normal subjects the average content of protein-bound hexoses in the serum was 116, and of protein-bound glucosamine 103 mg. per cent. The former value is in accord with that of other authors, but the latter is considerably higher. The average value for total serum polysaccharides was 220 mg. per cent. Towards the end of pregnancy there was a distinct increase of both the separate fractions and the total polysaccharides of the serum. In the course of 96 hr. after parturition the total polysaccharides fell, rising again during the following days. The minimum was almost entirely due to a decrease of glucosamine, and the rise to an increase of protein-bound hexoses. Serum glucosamine was inversely proportional to glucuronic acid, but no relation was found between the latter and protein-bound hexoses in the serum.—M. B. Richards.

PAGE, E. W., GLENDENING, M. B., DIGNAM, W. and HARPER, H. A. **The causes of histidinuria in normal pregnancy.** *Amer. J. Obstet. Gynecol.*, 1954, **68**, 110–118. [Dept. Obstet. Gynaecol., Univ. California Sch. Med., San Francisco.]

Plasma and urinary values and renal clearances were studied on 10 normal pregnant women at from 12 to 35 weeks of gestation, who received intravenous infusions of inulin and L-histidine at a constant rate. Control data were provided by repeating the procedure on the same patients 4 to 7 weeks after delivery. Histidine was estimated microbiologically.

In all 10 subjects, increased glomerular filtration rates for inulin, and therefore for water and amino-acids, were found during pregnancy. It is added, from the literature, that discrepant findings are due to the fact that the filtration rate returns almost to non-pregnant levels during the last lunar month of pregnancy. Histidine

clearances were relatively greater than glomerular filtration rates, pointing to diminished tubular re-absorption. Calculation from the data suggested the existence of a reduced rate of histidine metabolism during pregnancy.—A. M. Thomson.

GOVAN, A. D. T. and MACGILLIVRAY, I. **Renal function and chloride metabolism in pre-eclamptic toxæmia.** *J. Obstet. Gynaecol. Brit. Empire*, 1954, **61**, 491-496. [Res. Dept., Royal Maternity Hosp., Glasgow.]

A short salt-loading test was made on 2 normal non-pregnant women and 15 pregnant women; 8 of the latter had fairly severe pre-eclampsia and 4 had hypertensive disease with renal insufficiency. After preliminary observation, 200 ml. of 5 per cent. NaCl were injected intravenously, and observations were continued for 3 hr. In normal pregnancy, urinary volumes were slightly and in pre-eclampsia considerably diminished; in chronic nephritis complicating pregnancy they were greatly raised. In all groups, salt injection caused a peak urinary output in the first hour. The total chloride excretion tended to run parallel with the urinary output curve. In toxæmic and nephritic patients the blood chloride clearances tended to run parallel with urinary volume, but in normal patients, both pregnant and non-pregnant, parallel with urinary chloride concentration. The latter was somewhat similar in all groups, reaching a peak in the second hour in all pregnant women, but still rising in the third hour in the non-pregnant. Allowing for "endogenous" levels of chloride excretion, 9 per cent. of the injected Cl was eliminated in 3 hr. in normal pregnancy, compared with 4.5 per cent. in pre-eclampsia and 30 per cent. in nephritis complicating pregnancy. The difficulty toxæmic patients have in eliminating water and chlorides, manifested by low urinary volume and low total Cl excretion, is considered to be due not to renal damage but to active re-absorption by the renal tubules, a phenomenon differing only in degree from that present in normal pregnancy. By contrast, interference with the re-absorptive mechanism in chronic nephritis results in relatively high excretion levels.—A. M. Thomson.

During the first 2 weeks of pregnancy in rats there was a considerable increase in carcass moisture and a smaller increase in carcass fat, which accounted for most of the increase in total bodyweight; N retention was slightly greater than in non-pregnant controls. From about the 15th day of gestation there were marked increases in body, foetus and liver weights, a rapid fall in carcass fat, a rise followed by a fall in carcass N and continued water retention. N retention increased, and blood amino-N and urea formation and alanine-glutamate transamination in the liver decreased. At and after parturition there was a rise in blood urea, and the other values returned to normal.—C. Warner.

NELSON, M. M. and EVANS, H. M. **Maintenance of pregnancy in the absence of dietary protein with estrone and progesterone.** *Endocrinology*, 1954, **55**, 543-549. [Inst. Exp. Biol., Univ. California, Berkeley.]

Female rats in groups of 10 to 14 received a protein-free diet from the day of mating. Different groups received daily from the third day subcutaneous injections of 0.5 µg. oestrone, 4 mg. progesterone, 0.5 µg. oestrone plus 4 mg. progesterone, or sesame oil alone, or no injection. They were killed 13 or 21 to 23 days after mating.

In protein-deficient rats not given hormones, red cells appeared after 9 to 10 days in the vaginal smear, indicating foetal resorption. All the rats killed on day 13 showed small implantation sites, but at the end of gestation sites were found in only 60 per cent. From 90 to 100 per cent. of foetuses were resorbed.

Oestrone was somewhat beneficial, foetal deaths began later and 20 or 30 per cent. of the rats examined contained living young. Progesterone maintained pregnancy in 70 or 80 per cent. of the 30 rats. The number of implantation sites was normal, but the average number of living young per litter was only 6. Progesterone with oestrone maintained pregnancy in all the 30 rats, and the number of living young per litter was nearly normal. These animals lost less bodyweight than other groups, but were oedematous. They did not eat more.

In a second experiment the best dose of oestrone was found to be 2 to 3 µg. daily, with which 70 to 80 per cent. of the rats had living young. Higher and lower levels were less valuable.

- SCOTT, J. M. **The metabolism of iron in pregnant patients treated with massive drip infusions.** *J. Obstet. Gynaecol. Brit. Empire*, 1954, **61**, 641-645. [Res. Dept., Royal Maternity Hosp., Glasgow.]

Fe balance was studied in 6 anaemic patients in the last trimester of pregnancy, after treatment by massive drip infusion of Fe, each patient receiving the equivalent of 1 g. Fe intravenously over 8 hr. Three patients received a saccharated compound of ferrous Fe and the other 3 a ferric compound of similar type. During the 24 hr. after the infusion began the average urinary excretion of Fe was 1.1 per cent. with the ferric and 0.1 per cent. with the ferrous compound; none of the Fe was detected in the faeces. The average maximum serum Fe value in the ferrous salt group was 1.59 and in the ferric salt group 3.75 mg. per cent. Ferrous Fe was thus more readily taken up by the tissues than ferric. Food produced a rise in the serum Fe. It is emphasised that as reactions to drip infusion may be severe in some patients the method cannot be recommended for routine use.—G. F. Garton.

2447

- NYLANDER, G. **The placental transfer of intravenously administered high molecular ferric carbohydrate.** *Acta Soc. Med. upsalien.*, 1954, **59**, 372-382. [Dept. Histol., Univ. Upsala.]

The Fe preparation was Ferrigen (in U.S. called Astrafer), in which the active principle is a high-molecular ferric carbohydrate, with about 20 mg. elemental Fe per ml. Each of 51 rats received 1 ml. Ferrigen intravenously 24 hr. before being killed; they were in 5 groups, pregnant for 15, 17, 19, 20 and 21 days. The 83 controls at the same stages of pregnancy received no Fe injection.

In all rats the plasma Fe values were almost doubled 24 hr. after Ferrigen injection; the mean was 265 ± 13.1 μ g. per cent., irrespective of duration of pregnancy. All the Fe was protein-bound. Hydrolysable Fe in the liver was about 4 times the normal amount. The total and hydrolysable Fe of the foetus were increased above those of un-injected controls in the earlier stages, but only slightly in those at the end of gestation. The final Fe concentration in the foetus was simply reached earlier than usual. The placental membranes collected much Fe at all stages, and especially towards the end of pregnancy in rats given Ferrigen. In these animals the membranes con-

tained much hydrolysable Fe at all stages instead of only at the twentieth and twenty-first days.

D. Duncan.

2448

- NYLANDER, G. **Histochemically demonstrable iron in the placental organs of the rat after intravenous administration of a high molecular ferric carbohydrate.** *Acta Soc. Med. upsalien.*, 1954, **59**, 363-371. [Dept. Histol., Univ. Upsala.]

The same rats were used as in the preceding abstract. Foetal membranes from 10 of these Ferrigen-treated females were examined histologically and compared with those from untreated pregnant rats.

In the villous portion of the yolk sac and in the allantoic placenta there were numerous crystals of ferritin, more and larger from the rats which had received Ferrigen. Reichert's membrane in these animals also stained more intensely with Turnbull's blue, as did phagocytic cells of the allantoic placenta.

It is concluded that the placental barriers effectively prevented the ferric carbohydrate compound from reaching the foetus.—D. Duncan.

- HYTTEN, F. E. **Clinical and chemical studies in human lactation. 8. Relationship of the age, physique, and nutritional status of the mother to the yield and composition of her milk.** *Brit. Med. J.*, 1954, **ii**, 844-845. [Dept. Midwifery, Univ. Aberdeen.]

The yield and composition of milk on the seventh day of lactation was studied in 155 primiparae. There was a highly significant negative correlation between milk yield and age and between milk yield and net weight change in pregnancy. Fat content was not related to either age or weight change. In general, women of good health and physique tended to have higher milk yield of higher fat content than women of poorer health and physique. Data from a diet survey of 55 of the women in the seventh month of pregnancy showed no relation between diet and yield or composition of milk.—F. C. Aitken.

- MOHR, H. **Klinische Untersuchungen zur Steigerung der Laktation. [Clinical studies in stimulating lactation.]** *Deutsch. med. Wochenschr.*, 1954, **79**, 1513-1516. [Frauenklin., Univ. Tübingen.]

Since vitamin B₃ and Alyt, a proprietary extract of *Agnus castus* (*Vitex agnus-castus*), had been reported as increasing proliferation of the breast epithelium and secretion of milk, a trial was made in which, in all, 362 mothers were not

treated, 353 were given Alyt, 15 drops thrice daily before food, and 102 were given vitamin B₁, 1 tablet thrice daily [amount per tablet not stated]. Up to the time of discharge of the well mothers there was no apparent difference between the average milk yields of the groups, but of those with complications, who remained in hospital for 11 to 20 days, those with Alyt produced significantly more milk than the others and the difference increased with duration of stay in hospital. [Yield appears to have been assessed by test weighing of the babies.]—I. Leitch.

FLUX, D. S. Note on variations in the udders of monozygotic cattle twins. *N.Z. J. Sci. Technol.* [A], 1954, 36, 287. [Dairy Res. Inst. (N.Z.), Palmerston North.]

In 6 pairs of identical twin heifers the yields of the 4 quarters of the udder were measured separately on 4 occasions during lactation. Statistically significant differences were found between twin pairs in the relative amounts of milk obtained from the front and rear quarters. The amounts of milk produced by the right and left sections of the udder did not differ significantly.

Post-mortem examination of the udders of a pair of twins of which one gave no milk from one front teat and the other none from either front teat showed that these teats had small sinuses which ended as blind sacs. It was concluded that the abnormality was inherited.—J. N. Aitken.

HANCOCK, J., BRUMBY, P. J. and TURNER, C. W. Hormonal induction of lactation in identical twin dairy cattle. *N.Z. J. Sci. Technol.*, 1954, 36, 111-116. [Ruakura Animal Res. Stat., Dept. Agric., Hamilton, N.Z.]

Lactation was induced by hormones in one member of each of 7 pairs of monozygous heifers. Mammary growth was obtained by injecting 50.05 mg. progesterone and diethylstilboestrol, in the ratio 1000 : 1, daily for 60 days, followed by 75.075 mg. daily for 30 days and 100.1 mg. daily for 60 days. Induction of lactation was begun on the 30th day of the last period by injecting an additional 2 mg. diethylstilboestrol daily, increased to 4 mg. on the 40th and 8 mg. on the 50th day and continued until each animal's twin calved. Regular milking twice daily then began. The lactation fat-corrected milk yield of the treated animals ranged from 10.8 to 106.9 per cent. of that from their normally bred twins. The poor milk yield of 3 of the treated animals was due to genetic limitations. The other 4 heifers yielded "normal" amounts with lactation totals from 2404 to 4366 lb. fat-corrected milk.—J. L. Corbett.

DONKER, J. D., KOSHI, J. H. and PETERSEN, W. E. The effects of hourly milking with the aid of intravenous injections of oxytocin. *J. Dairy Sci.*, 1954, 37, 1261-1268. [Dept. Dairy Husb., Univ. Minnesota.]

2454

SHAFFHAUSEN, D. D., JORDAN, R. M. and DRACY, A. E. The effect of relaxin upon milk ejection. 1. The let-down effect upon sheep. *J. Dairy Sci.*, 1954, 37, 1173-1175. [Dept. Animal Husb., S. Dakota Agric. Exp. Stat., Brookings.]

Ten ewes were hand-milked after the lambs had been removed for 12 hr. Immediately after this milking 500 guineapig units relaxin were injected intravenously and the ewes were milked again after 1 min. Milking was again repeated after 10 I.U. oxytocin were given intravenously. The first milking gave 39.1 per cent. of the milk, the second 43.5 and the third 17.4. Relaxin may have a contracting effect upon the alveoli as well as a relaxing effect upon the symphysis pubis.

SWANSON, E. W. The effect upon milk production and body weight of varying withdrawal periods after thyroactive supplement feeding. *J. Dairy Sci.*, 1954, 37, 1212-1219. [Dairy Dept., Univ. Tennessee, Knoxville.]

In experiments with 28 Holstein and Jersey cows the effects of different rates of withdrawal of a thyroid-active supplement on milk production were studied. Withdrawal of the material occupied 10, 15, 18, 25 or 30 days, after treatment for 14 weeks.

Withdrawal in 10 days resulted in a rapid drop in milk yield to below the expected normal. When withdrawal took 15 days or more the decline in milk yield was slower and yield did not fall below the expected normal. Treated cows lost weight, but rapidly recovered after cessation of treatment. Paunch girth showed that the increased body-weight gains were largely due to an increase in gastro-intestinal contents.

In 2 sets of identical twins, 1 of each pair treated and its mate used as control, body water estimated by the antipyrine method showed no effect of treatment.—J. N. Aitken.

N.A. and R., April 1955

After injection of ^{35}S -methionine into the jugular vein of a lactating goat, maximum activity was found in the milk within 1.5 hr., about half the ^{35}S appearing in protein within 8 hr. The activity of the casein was at all times slightly higher than that of the whey proteins, possibly because the latter contained some low-activity blood protein. When ^{14}C -labelled glycine, valine and lysine were injected, the activities of these amino-acids isolated from casein, purified β -lactoglobulin E and crystalline β -lactoglobulin G were identical, suggesting that the N pool for the formation of casein and of lactoglobulin was identical and in equilibrium with circulating blood amino-acids. Serine isolated from the casein, and presumably formed from the labelled glycine, had a higher activity than that from the lactoglobulin.—C. Warner.

BLACK, A. L. and KLEIBER, M. **Level of fixed carbon in amino acids of casein measured in the intact dairy cow.** *J. Biol. Chem.*, 1954, **210**, 895–902. [Univ. California Sch. Vet. Med., Davis.]

^{14}C -Labelled NaHCO_3 was injected intravenously into a cow which was then milked at intervals, and the radio-activity of amino-acids prepared from the casein of the milk was measured. High specific activity was first found in aspartic acid and persisted longest in glycine; alanine at 11 hr. showed the highest specific activity of all tests. From 4 to 8 per cent. of the carbon of aspartic acid, glutamic acid, serine, glycine, alanine and arginine was derived from blood CO_2 , about 1 per cent. of the C of proline, valine, methionine and lysine, and 0.1 to 0.6 per cent. of that of threonine, the leucines, tyrosine, phenylalanine and histidine.

KLEIBER, M., BLACK, A. L., BROWN, M. A., LUTCK, J., BAXTER, C. F. and TOLBERT, B. M. **Butyrate as a precursor of milk constituents in the intact dairy cow.** *J. Biol. Chem.*, 1954, **210**, 239–247. [Coll. Agric., Univ. California, Davis.]

Four lactating cows were injected with sodium butyrate- $1\text{-}^{14}\text{C}$ and $2\text{-}^{14}\text{C}$. The specific activity of the expired CO_2 was greatest after 10 and 30 min., respectively, and was greatest in the CO_2 derived from the carboxyl group, which was oxidised at a rate between those of the similar groups in acetate (Abst. 729, Vol. 23) and propionate (Abst. 778, Vol. 24).

About 6 and 22 per cent. of the $1\text{-}^{14}\text{C}$ and $2\text{-}^{14}\text{C}$ appeared in organic milk constituents, much less in fat than in lactose and casein. Acetate labelled in the 1 or 2 position produced the greatest activity in milk fat. This suggests that not much of the

transfer of C from butyrate to lactose takes place through acetate, and if β -oxidation is involved the 2-carbon units evidently favour carbohydrate over fat synthesis.

Data indicate that the transfer of the carboxyl carbon of butyrate to lactose, casein and milk fat was about 27, 18 and 8 per cent. by CO_2 fixation. The corresponding figures for $2\text{-}^{14}\text{C}$ were 15, 6 and 6.—A. Hepburn.

PEETERS, G., COUSSENS, R. and SIERENS, G. **The detection of a ketoheptose sugar in colostrum and udder tissue from cows.** *Naturwissenschaften*, 1954, **41**, 428–429. [Dept. Physiol., Vet. Sch., Univ. Ghent.]

Extracts of colostrum, normal milk and udder tissue were compared by paper chromatography with standards of pure mammoheptulose and of juice expressed from fresh *Sedum spurium* and known to contain sedoheptulose. In normal milk no ketoheptose was detected, but sometimes in colostrum and often in udder tissue extracts there was a substance with the characters of sedoheptulose. The ketoheptose sugar, it is suggested, may be an intermediate product in the carbohydrate metabolism of the mammary gland.—D. Harvey.

SMITH, A. H., WILSON, W. O. and BROWN, J. G. **Composition of eggs from individual hens maintained under controlled environments.** *Poultry Sci.*, 1954, **33**, 898–908. [Coll. Agric., Univ. California, Davis.]

Six hens in each of 2 experiments were given a practical laying ration with P contents of 0.8 and 1.0 per cent., respectively. Sunlight was excluded from all houses, and continuous artificial light was given. Eggs were collected twice daily and stored at 55° F. until analysed within 1 or 2 days. In trial 1, the hens were kept at temperatures of 60° F. for 26 days, then at 80° F. for 30 days, with acclimatisation periods of 34 and 33 days. In trial 2, the experimental conditions were 60° F. and 90° F. for 40-day periods, preceded by 50 days and no acclimatisation period, respectively.

The eggs of the experimental birds differed from accepted standards. The shells were relatively light and the whites relatively heavy. The levels of Na and K on water content basis were the same in the white and the yolk, which suggested that these elements were in solution; the Ca levels were similar in the white and the yolk on a dry fat-free basis, suggesting that Ca was protein-bound. The P levels of yolk and white were dissimilar on any basis; 8.7 per cent. of the total P was inorganic in the white and 4.7 per cent. in the yolk. A significant positive correlation was found between inorganic P of the yolk and laying rate. There was also a slight correlation between the level of P compounds in the white and laying rate, which indicated that the deposition of inorganic P in the white was intermittent. Level of P in the shell was not affected by the laying rate. A difference was found in the Na:K ratio of white and yolk, and its bearing on embryo growth is discussed. The composition of eggs varied much between birds, but individually was nearly constant. There was a suggestion that the age of the bird influenced the composition of the egg.

The rise in ambient temperature decreased both egg size and laying rate in direct proportion. The dry matter of the yolk decreased, that of the white increased. At higher temperatures the total P level of the white and the yolk rose, but the inorganic P level of the yolk fell. These changes in composition are also associated with a low laying rate. The high temperature increased the Na and K content of the yolk, especially the Na.

M. J. Head.

SMITH, A. H., WINGET, C. M. and BLACKARD, J. R. The transfer of phosphorus to the hen's egg, under controlled environment, as traced with radiophosphorus (F^{32}). *Poultry Sci.*, 1954, **33**, 908-919. [Coll. Agric., Univ. California, Davis.]

The conditions of this experiment were the same as in the previous Abst. At the beginning of each experiment each hen received intramuscularly 180 to 350 μ C. of 32 P.

Less than 2 per cent. of the injected P appeared in the shell within 12 days unless an egg was laid soon after injection; 2 per cent. appeared in the shell of an egg laid 2 hr. after injection. The maximum amount of radio-activity always occurred in the first shell laid.

Less than 1 per cent. of the injected 32 P reached the white in the first 12 days and maximum activity was encountered in the second egg laid except when it was 3 or more days afterwards.

Of the injected dose 10.8 per cent. reached the yolk in the first 12 days and 4.2 per cent. in the next 12. Maximum activity was in the fourth or

fifth egg, that of inorganic P preceding that of organic P by 38 hr.

Kinetic analysis of the rate of 32 P transference indicated the existence of 2 major P pools, one renewed every 1.4 days and holding 18 per cent. of the total P, and the other renewed in 14 days holding 82 per cent.—M. J. Head.

TYLER, C. A further study of the effect of sulphanilamide on the metabolism of calcium and phosphorus in the laying hen. *J. Agric. Sci.*, 1954, **45**, 156-163. [Dept. Agric. Chem., Univ. Reading.]

As an extension of earlier work (Abst. 1208, Vol. 21) a calcium and phosphorus balance experiment was made with 6 pullets for 10 consecutive periods each of 8 days. In the second and third periods each bird received a daily supplement of either 0.036 or 0.072 g. sulphanilamide.

The sulphanilamide appeared to have no significant effect on the number of eggs laid by the birds either immediately or in the next 8 months. The daily ration contributed 2.75 g. Ca and 1.06 g. P, and in the preliminary period the birds were all in positive balance or equilibrium for both minerals. At the time of, and for 5 weeks after, receiving sulphanilamide Ca retention was reduced. During sulphanilamide feeding the eggs laid were thinner shelled so that the balance was little affected. Afterwards shell thickness returned rapidly to normal, so that for several weeks the birds were in negative Ca balance as a result of persisting impairment of retention.

Statistical analyses were made in an attempt to relate individual differences in Ca retention to the level of egg production, and to concurrent changes in P metabolism.—K. J. Carpenter.

TYLER, C. and GEAKE, F. H. Studies on egg shells. 5. Some physical and chemical characteristics of the egg shells of five different types of

N.A. and R., April 1955

pheasant. *J. Sci. Food Agric.*, 1954, **5**, 612-619. [Dept. Agric. Chem., Univ. Reading.]

Egg shells from 5 types of pheasants, 4 reared in captivity and the other trapped before laying, were examined for shell thickness, porosity coefficients, pore counts, membrane-, pore- and matrix-protein, citric acid, carbonate, Ca, Mg and P. There were considerable differences between the types, with the wild type usually at one or other end of the range. Equations relating shell weight to Ca content and carbonate to Ca content were similar to those from hen egg shells (Abst. 3494, Vol. 24) but the relation between shell thickness and weight per unit area was different.—A. Hepburn.

2467

RAMSAY, W. N. M. and CAMPBELL, E. A. Iron metabolism in the laying hen. *Biochem. J.*, 1954, **58**, 313-317. [Dept. Biochem., Univ. Edinburgh.]

Plasma Fe and Hb were estimated in samples of blood taken at intervals of about 3 weeks from pullets before laying and throughout a laying season. Plasma Fe rose from below 250 μg . per 100 ml., 10 days before laying, to become 500 and 900 μg . per 100 ml. during egg production. High plasma Fe values were significantly correlated with high values for total egg Fe.

From analyses of liver, spleen and kidney it was concluded that the increased Fe requirement during egg laying was provided by increased efficiency of absorption rather than by depletion of tissues.—R. Hill.

EXPERIMENTAL STUDIES OF IMMUNITY AND MICRO-ORGANISMS

2476

FABIANI, G. and ORFILA, J. Action du régime lacté sur le paludisme expérimental de la souris blanche. [Effect of a milk diet on experimental malaria in the white mouse.] *C.R. Soc. Biol.*, 1954, **148**, 1239-1241.

Adult mice received a milk diet without added vitamins; 9 had fresh and 23 condensed cow's milk. After 3 to 5 days on the diet they were

inoculated with *Plasmodium berghei*, and the percentage of parasitised red cells was counted every second day.

The effect of the milk diet was irregular; in some mice there was little development of the parasites, in others an irregular fluctuation, in others again the parasites began after about 12 days to increase slowly but regularly, and these mice eventually died. The development of reticulocytosis also was

erratic and dissociated from that of the parasites, and in some animals there were large numbers of free reticulocytes when few parasites were present. Mice which survived the infection on milk diet were later returned to stock diet and re-inoculated; they developed a slight infection which was cured, thus demonstrating the persistence of immunity acquired in resisting the massive infection on milk diet.

The complex effect of the milk diet is discussed.

BUYZE, H. G. Het verschil tussen moedermelk en koemelk ten aanzien van de Bifidusfactor. [Difference between human milk and cow's milk in respect of the bifidus factor.] *Voeding*, 1954, 15, 488-493. [Centraal Inst. Voeding-sonderzoek T.N.O., Utrecht.] English summary.

The recent work of György and his colleagues (Abst. 3509, Vol. 24), who isolated a group of oligo- or polysaccharides containing an acetylglucosamine group from breast milk, meconium, semen, tears and gastric mucus, and Tomarelli *et al.* (Abst. 3510, Vol. 24), who isolated from pig stomach mucus a similar compound with a stimulating effect on the growth of a pure culture of a mutant of *Lactobacillus bifidus* (var. *Penn.*) is reviewed. The activity of the compound from stomach is small compared with that of breast milk. In comment it is said that these results cannot fully explain the difference between human and cow's milk. The mutant used represents only a small part of the normal bifidus flora of breast-fed infants and the production of a complete, or near-complete, bifidus flora is not explained.

JACKSON, G. G., GABUZDA, G. J. and FINLAND, M. (with HIRSCHBERG, E. A., DE CARLI, L., WILCOX, C. and BRODERICK, M. K.) Effect of antibiotics on organisms used in certain microbiologic assays of essential nutrients. *J. Lab. Clin. Med.*, 1954, 44, 449-462. [Thorn-dike Mem. Lab., Boston City Hosp., Mass.]

This work was undertaken to find how far antibiotics may affect the results of microbiological estimation of amino-acids, folic acid, riboflavin, nicotinic acid, pyridoxine and citrovorum factor.

The sensitivity of assay organisms, *Streptococcus faecalis*, *Lactobacillus casei* (2 strains), *Lactobacillus delbrueckii*, *Leuconostoc citrovorum*, *Lactobacillus arabinosus* and *Saccharomyces carlsbergensis*, to 9 antibiotics was studied in heart infusion agar, brain-heart infusion broth and the defined media employed for the particular microbiological estimation for which each organism was used.

The antibacterial effects of penicillin, chlortetracycline and chloramphenicol were influenced by the medium less than those of the other antibiotics; the antibacterial titres of bacitracin and erythromycin were always much less in assay media than in meat infusion media; with streptomycin, neomycin, polymyxin and oxytetracycline results differed with the test organism.

Because antibiotic-containing materials submitted for microbiological assay may be autoclaved before assay, the effect of autoclaving at 15 lb. for 15 min. upon the antibacterial titres of the antibiotics was investigated. Autoclaving completely inactivated chlortetracycline and oxytetracycline below the level of 200 µg. per ml.; chloramphenicol was stable and remained bacteriostatic above 12.5 µg. per ml.

N.A. and R., April 1955

Chlortetracycline, oxytetracycline or chloramphenicol, added before or after autoclaving, could not replace essential amino-acids for growth of *S. faecalis*, nor could they replace phenylalanine or tyrosine for *L. casei* or *L. delbrueckii*. Autoclaved chlortetracycline could not replace nicotinic acid, riboflavin, pyridoxine or citrovorum factor for the growth of the appropriate assay organisms.

Graded amounts of riboflavin, up to 0.1 µg. per ml. medium, were without effect upon the bacteriostatic titre of chlortetracycline towards *L. casei*. The presence of riboflavin, folic acid and citrovorum factor in the relatively high concentrations of 10 or 50 µg. per ml. assay medium did not alter the sensitivity of *L. casei* to chlortetracycline.

EADIE, J. M. and OXFORD, A. E. A remarkable disintegrative effect of skatole upon certain rumen ciliate protozoa. *Nature*, 1954, 174, 973. [Rowett Res. Inst., Bucksburn, Aberdeenshire.]

Anaerobic protozoa from the sheep's rumen, *Isotricha*, *Dasytricha* and *Ophryoscolex*, which could be kept active in buffer solution for several hours, were found not only to be killed by indole and skatole, as previously reported by Hogg and Elliott (*J. Biol. Chem.*, 1951, 192, 131) for *Tetrahymena pyriformis*, but, at near saturation point, to be rapidly and completely disintegrated with liberation of intracellular inclusions. Isatin and 2- and 7-methylindoles produced a similar though sometimes less rapid result; some indole derivatives related to tryptophan were of low toxicity and without disruptive effect. It appeared that toxicity was determined not only by molecular structure but also by physical properties.

It is concluded that toxic indole derivatives in the rumen, resulting from bacterial proteolysis there, may be expected to affect the protozoal population.—J. C. Appleby.

BRYANT, M. P. and DOETSCH, R. N. A study of actively cellulolytic rod-shaped bacteria of the bovine rumen. *J. Dairy Sci.*, 1954, 37, 1176-1183. [Dairy Husb. Res. Branch, U.S. Dept. Agric., Beltsville, Md.]

Of Gram-negative cellulolytic rods isolated from rumen contents, 8 strains showing fundamental physiological agreement were selected for more detailed biochemical examination, including carbohydrate fermentation tests. A technique for preparing anaerobic cultures for estimation of end products is described.

No growth was obtained unless the authors' more usual Trypticase and yeast extract were supplanted by 20 per cent. rumen fluid. Only

glucose, cellobiose, cellulose and pectin were attacked by all strains. The end products of cellulose fermentation of the 2 strains with the widest morphological differences were closely comparable and were legitimate constituents of rumen liquor. The organisms were identified as *Bacteroides succinogenes*, although they had not all its fermentative powers. With glucose medium, the relations of one strain with temperature and reaction were studied, and some growth requirements were investigated. Substitution of bovine saliva, faeces extract, alfalfa meal extract, or a complex synthetic solution for rumen fluid failed to produce comparable growth of this strain. It is concluded that a hitherto unknown growth substance, stable to heat, acid, and alkali, is present in rumen fluid.—E. S. M. Mackay.

2485

MACKAY, E. S. M. and OXFORD, A. E. Some facultatively anaerobic gram-negative rods from the rumen of the calf and the sheep. *J. Gen. Microbiol.*, 1954, 11, 472-476. [Rowett Res. Inst., Bucksburn, Aberdeenshire.]

The rumen contents of 12 calves aged 1½ to 15 weeks were collected at slaughter. Gram-negative rods were isolated by plating on a crystal violet medium and anaerobic incubation.

Numbers of coliform bacteria in individual calves ranged from none to 10⁶ per g. rumen contents. Of 39 isolates 34 were negative to the Voges Proskauer reaction and methyl red positive, and 5 were V.P. positive and M.R. negative. Capsulated *Aerobacter aerogenes* was not encountered; this organism was isolated readily from the rumen of a sheep fed on starch and concentrates, but not of sheep fed on hay.

From the older calves a urea-splitting Gram-negative rod was isolated on 9 occasions. This was not assigned to any known genus, but a description is given.—J. C. Appleby.

BELASCO, I. J. Comparison of urea and protein meals as nitrogen sources for rumen micro-organisms. Urea utilization and cellulose digestion.

The production of volatile fatty acids. *J. Animal Sci.*, 1954, 13, 739-747; 748-757. [Polychem. Dept., E.I. du Pont de Nemours and Co., Wilmington, Del.]

In an artificial rumen the efficiency of urea as a source of N for cellulose digestion by rumen micro-organisms was compared with that of high-protein meals.

Urea alone (in the presence of starch), soya bean meals alone, and urea and soya bean meals in 1:1 mixtures were investigated at 93.5, 187 and 374 mg. N levels. This plan was repeated with maize

gluten meals, cottonseed meals and linseed meals replacing soya bean meals. Estimations of urea and ammonia provided an indication of the rate of urea utilisation, but a similar procedure was not applicable with the protein meals. The rate of cellulose digestion always proved a reliable indicator of N utilisation, and within limits the relation between N supply, N utilisation and cellulose breakdown was linear.

At equivalent N levels, and especially at the lower levels, urea gave better cellulose breakdown than did any protein meal, and it was more completely utilised in the urea-protein mixtures. Increasing amounts of urea from 1.3 per cent. to 35 per cent. protein equivalent levels, but not more, resulted in comparable increases in cellulose digestion. Detailed results are tabulated.

In similar tests volatile fatty acids were estimated by chromatographic technique, of which details are given. Urea as N source gave a consistent increase in propionic acid, presumably as a result of more active cellulose digestion. Higher production of butyric and possibly of valeric acid in the presence of protein meal supplements was attributed in part to protein degradation. The proportion of acetic acid did not vary significantly.

BROOKS, C. C., GARNER, G. B., GEHRKE, C. W., MUHRER, M. E. and PFANDER, W. H. The effect of added fat on the digestion of cellulose and protein by ovine rumen microorganisms. *J. Animal Sci.*, 1954, **13**, 758-764. [Univ. Missouri, Columbia.]

To a cellulose-containing medium in artificial rumens was added maize oil in amounts varying from 10 to 170 mg. per 25 ml., and these were inoculated with rumen fluid from a sheep on a high-cellulose diet. Cellulose breakdown, estimated after 40 hr. at 39° C., was significantly less than in control preparations, by 93.9 per cent. with 160 mg. oil.

The effect of fats on digestion of cellulose and protein *in vivo* was investigated in crossbred yearling wethers. From 32 to 64 g. maize oil or lard was added to about 1 kg. basal diet of casein and cottonseed hulls, and protein and cellulose were estimated in 4-day collections of faeces. Digestion of cellulose and protein was impaired, with some loss of appetite, particularly by maize oil. Addition of alfalfa ash to the diet prevented to some extent the inhibition of digestion by the fat. In the rumen, volatile fatty acid production was less in the presence of fats. The total number of rumen bacteria did not appear to be altered, but the flora became predominantly coccoid.

SCHENDEL, H. E., BORG, A. F. and JOHNSON, B. C.
The effect of antibiotics on the intestinal and cecal microflora of baby pigs fed a "synthetic milk". *J. Animal Sci.*, 1954, **13**, 904-911. [Div. Animal Nutrit., Univ. Illinois, Urbana.]

Sixteen baby pigs were fed on "synthetic milk" with water-soluble vitamins added; half were given terramycin also, at the rate of 50 mg. per kg. dry matter of the feed. Growth rates were recorded.

When the pigs were killed after 5 weeks portions of the intestine were immediately isolated by ligaturing and contents of sections of the duodenum, jejunum, ileum and caecum were removed for bacteriological examination. Colony counts were made on beef liver infusion agar, malt agar, Rojosa's medium and deoxycholate agar. Mean peak counts for each specimen from 14 pigs showed that in the pigs given antibiotic the total count in each portion of the gut above the caecum was

about 10 times that in control pigs. These regions corresponded with those where, in the rat, highest concentrations of antibiotic were to be found by microbiological assay. There was no correlation between caecal counts and increased growth rates. From counts upon each medium it was concluded that the antibiotics produced no great qualitative change in the flora.

It was postulated that the increase in growth rates of animals given antibiotic might be related to a general increase in intestinal bacteria capable of synthesising nutrients.—J. C. Appleby.

MISCELLANEOUS FEEDING EXPERIMENTS

2497

BIXBY, J. N., BOSCH, A. J., ELVEHJEM, C. A. and SWANSON, A. M. **Factors affecting the nutritive value of cow's milk.** *J. Agric. Food Chem.*, 1954, **2**, 978-982. [Dept. Biochem., Coll. Agric., Univ. Wisconsin, Madison.]

Groups of 6 weanling rats weighing 40 to 45 g., housed individually, were fed on stock diet or on diets of milk treated in different ways with added Fe 3, Cu 0.15 and Mn 0.15 mg. per 100 ml. After 6 weeks they were killed and liver fat was estimated.

On the milk diets growth as measured by average weekly weight gains was good, though not quite as good as on the stock diet. Pasteurisation or homogenisation of the milk had no effect, nor was there a seasonal effect. These results are contrary to those of Elvehjem and others before the war (Absts. 3821, Vol. 4; 2286, Vol. 6; 3156, Vol. 7; 1970, Vol. 8); the reason suggested is that milk produced now may be higher in nutritive value than formerly. Liver fat was higher in all milk-fed rats; the effect was slightly less with homogenised milk. Supplements of choline, folic acid, vitamin B₁₂, methionine, lysine, threonine or glycine had little or no effect on growth or liver fat; a mixture of the first 3 reduced liver fat slightly. Mg slightly reduced growth. Addition of 10 per cent. sucrose or dried skimmed milk low in lactose slightly reduced liver fat. Further experiments with skimmed milk enriched with homogenised cream showed that liver fat increased

with the butterfat content of the milk but that growth did not vary much. Additional heat treatment at 185° F., but not at 145° or 165° F., of pasteurised homogenised milk slightly reduced growth but did not affect liver fat. Very good growth and low liver fat values were obtained with dried whole milk, either dry or reconstituted, and canned milk sterilised by the high-temperature short-time process.

Experiments carried through 3 generations, in which females received mineralised milk raw or pasteurised at 143° F. for 30 min. and were mated with males on stock diet, showed that pasteurisation had no effect on reproduction and lactation; but young of second and third generation females grew less well on raw or pasteurised milk than those of first generation females.—W. M. Deans.

APPANNA, T. C. and DEVADATTA, S. C. **The effect of prawn protein on the bone of mature rats.** *Proc. Indian Acad. Sci.*, 1954, **40**, 44-48. [Christian Med. Coll., Vellore.]

Six groups of 10 mature rats were given synthetic diets with prawn (*Parapaenopsis sculptilis*) pulp as the only source of protein other than the small amount of yeast supplied. It constituted 7.5, 10, 12.5, 15, 17.5 or 20 per cent. of the diet. Food intake and bodyweight were recorded and after 30 days the rats were killed. Length, dry fat-free weight and the ash, Ca and P contents of the humerus were estimated. Loss of weight

occurred and skeletal development was poorest in the group with the lowest amount of prawn pulp. With the 3 highest amounts mean weight increases and skeletal development were the same. The composition of the bone judged by its Ca : P ratio in the ash was not affected by the differences in protein level. [Throughout the paper the group with the lowest amount of prawn pulp is referred to as the 5 per cent. group.]—D. Harvey.

WESTERMAN, B. D., OLIVER, B. and MAY, E. Improving the nutritive value of flour. 6. A comparison of the use of soya flour and wheat germ. *J. Nutrition*, 1954, 54, 225-236. [Dept. Foods Nutrit., Kansas Agric. Exp. Stat., Manhattan.]

For part 5 see Abst. 743, Vol. 23.

Albino rats at 24 days of age were given a vitamin-B-free diet for 10 to 14 days to deplete their reserves of these vitamins. They were divided into 8 groups of 10 equal as to sex and littermates. Seven groups were given diets of natural foods similar to those consumed by man. The cereal component which supplied 52 per cent. of the calories was enriched or non-enriched flour with or without supplements of 3 per cent. wheat germ or 3 per cent. soya flour. The eighth group was given stock diet. The rats were weighed weekly for 12 weeks; they were then mated and carried through 3 pregnancies and lactations. The young were used in a second generation growth trial and the first generation were killed and their muscle and liver tissue was analysed for vitamin B₁, riboflavin, nicotinic acid and pantothenic acid.

Soya flour or wheat germ added to unenriched or enriched flour significantly improved growth. There was no significant difference between the effects of these supplements except in the second generation tests with unenriched flour, when soya flour was more effective than wheat germ in promoting growth. Reproduction and lactation as judged by the numbers of young produced and weaned were best in the group given enriched flour with wheat germ and second best in the group given unenriched flour with soya flour.

Wheat germ added to unenriched flour resulted in significantly greater storage of vitamin B₁ in liver and muscle and greater storage of riboflavin in liver; soya flour significantly increased storage of riboflavin in liver.—F. C. Aitken.

SURE, B. Relative nutritive values of proteins in whole wheat and whole rye and effect of amino acid supplements. *J. Agric. Food Chem.*, 1954, 2, 1108-1110. [Dept. Agric. Chem., Univ. Arkansas, Fayetteville.]

Whole rye flour was superior to whole wheat flour as sole protein source for rats, as measured by growth over 10 weeks and protein efficiency. The nutritive value of whole flour was increased by supplementation with lysine and threonine, that of whole rye flour by valine.—C. Warner.

2501

GREER, E. N. and GRINDLEY, G. G. The late maturing of winter wheat : an observation on the nutritive value of the grain. *J. Agric. Sci.*, 1954, 45, 125-128. [Res. Assoc. British Flour Millers, Cereals Res. Stat., St. Albans, Herts.]

Wheat grain was given as the sole source of protein to rats. Wheat containing more N as a result of application of fertiliser in the spring produced better growth than wheat not so fertilised. The ratio of growth rate to N intake suggested that the fertilised grain was not more acceptable, but had a greater nutritive value.

SUBRAHMANYAN, V., KUPPUSWAMY, S. and SWAMINATHAN, M. Possible influence of the quality of rice in determining the nutritive value of the poor rice diet. *Bull. Central Food Technol. Res. Inst. Mysore*, 1954, 3, 272-276.

A brief review of the results of animal experiments on the nutritional value of rice diets is reported. It shows a great variation in growth-promoting values; rates from 1 to 10 g. per week in albino rats are recorded by different workers. It is suggested that the difference may be due to the chemical composition of the varieties of rice used, the degree of milling, different characteristics of the experimental animals, or seasonal and climatic differences. It was considered from available evidence that varietal differences in the rice were probably the most important. Further investigation on these lines, with a view to standardising a satisfactory rice diet, is called for.

KIRK, M. C. **Nutritive value of rice germ.** *J. Agric. Food Chem.*, 1954, **2**, 1179-1181. [Dept. Agric. Chem., Univ. Arkansas, Fayetteville.]

Different methods for separation of rice germ from rice bran are outlined. Growth studies were made on groups of 6 male and 6 female rats and metabolism studies on groups of 24 animals. Four diets each contained 20 g. Cellu flour, 40 g. salt mixture, 40 g. vegetable fat, 10 g. maize oil plus vitamin mixture, 10 g. sucrose and biotin mixture and 10 g. sucrose and vitamin B complex mixture; the first diet also contained 870 g. milled rice, the second 756 g. milled rice, 50 g. rice germ and 64 g. cerelose, the third 382 g. rice germ and 488 g. cerelose and the fourth 603 g. rice germ and 267 g. cerelose. On these 4 diets bodyweight gains in 10 weeks were on the average 80, 103.8, 105 and 114 g.; the protein efficiency ratios of the diets, calculated from the gains in bodyweight per g. protein intake, were 1.76 ± 0.08 , 2.63 ± 0.11 , 2.59 ± 0.06 and 1.90 ± 0.10 . The biological value of the first diet was 61.4 ± 1.7 , and of the fourth diet 78.1 ± 1.3 .

The amino-acid content of rice germ was estimated microbiologically and results are compared with those published for milled rice. Figures are given for the content of B group vitamins, Ca, P, Fe and other constituents in rice germ.

KADKOL, S. B., SREENIVASAMURTHY, V. and SWAMINATHAN, M. **Nutritive value of the seeds of *Panicum miliare* (little millet).** *Bull. Central Food Technol. Res. Inst. Mysore*, 1954, **3**, 247-248. [Div. Biochem. Nutrit.]

Whole and husked seeds of *Panicum miliare* (little millet) were analysed. A table of the results, with wheat for comparison, is presented. Except for carbohydrate, calculated by difference, in the husked millet, and ether extract and total minerals in both forms, the values for wheat were all higher.

The comparative values of husked little millet and whole wheat as sources of protein, vitamin B complex and minerals, except Ca, were investigated. [Details or results are not given.] Comparative nutritive values as the staple grain in a poor vegetarian diet were also investigated by the rat growth method. The diets for this are described and a table of results, which shows whole wheat to be greatly superior to husked little millet, is presented.—T. D. Bell.

HIRWE, R. and MAGAR, N. G. **Effect of autoclaving on the nutritive value of pulses.** *Indian J. Med. Res.*, 1953, **41**, 191-200. [Inst. Sci., Bombay I.]

Vol. 25, No. 2

The growth of groups of 6 young albino rats was used to estimate the nutritive value of raw and autoclaved Bengal gram, dhal arhar, lentils, horse gram, black gram, green gram and field beans. The protein content of all the diets was 12 per cent.; the pulses were autoclaved at 15 lb. pressure for different periods. The diets were administered for 5 to 6 weeks, after which the animals were killed and the liver and kidneys were removed for estimation of protein and fat.

The nutritive value of the protein of Bengal gram, horse gram and field beans was improved by autoclaving, that of the other pulses was not. When methionine was added to raw pulses except dhal arhar and field beans the nutritive value was improved. There was no great difference in composition of livers from rats given the different diets.—G. F. Garton.

2507

MEYER, J. H. **The utilization of alfalfa and alfalfa fiber fractions by growing rats.** *J. Nutrition*, 1954, **54**, 237-247. [Dept. Animal Husb., Univ. California, Davis.]

The utilisation of alfalfa and its 3 fibre fractions, extracted alfalfa, holocellulose and lignin, was estimated by paired feeding, N balances and digestibility experiments with weanling rats fed on diets containing 10 and 35 per cent. protein.

Lignin did not produce weight gains or N retention and was slightly digested only when given with the low-protein ration. Holocellulose gave a small weight increase and N retention, but only with the low-protein ration; 8 to 14 per cent. holocellulose was apparently digested. With the low-protein ration alfalfa produced higher N retention than extracted alfalfa. In general weight gains closely followed N retention. With the high-protein rations alfalfa gave large increases in weight gain and extracted alfalfa gave only slight increases. N retentions were the same. This showed that extracted alfalfa was a valuable source of N, but not of energy; the soluble constituents were valuable for both. About 12 per cent. of the organic matter of extracted alfalfa was apparently digested, of soluble constituents from 69 to 75 per cent.—A. Hepburn.

2508

ROBERTS, R. S. **The nutritional properties of killed *Bacterium coli*.** *Brit. J. Nutrition*, 1954, **8**, 353-363. [Evans Biol. Inst., Runcorn, Cheshire.]

Cultures of *Bacterium coli* grown on an inorganic salt medium with glucose and sodium citrate were centrifuged and re-suspended in physiological saline and the cells were killed by heating at 80° C. for 1 hr. The bacteria were equivalent to fishmeal as a protein supplement for growth of

young rats receiving a basal diet of cereals and fish solubles. The optimum bacterial protein concentration was 1 to 2 per cent. A basal diet with 16.5 per cent. protein, 4 per cent. from *Bact. coli*, produced better growth in chicks than a mash with 18.3 per cent. protein containing fishmeal, liver meal, dried skimmed milk, dried whey and riboflavin. The promotion of growth by *Bact. coli* may be similar to that by antibiotics. Preparations of *Bact. coli* containing culture fluid were toxic.—A. Hepburn.

2509

HUBBELL, R. B. A comparison of two stock rations for albino rats. *J. Nutrition*, 1954, **53**, 429-438. [Connecticut Agric. Exp. Stat., New Haven.]

Mendel and Hubbell in 1935 (Abst. 4283, Vol. 5) reported growth and reproductive performance in the rat colony at the Connecticut Agricultural Experiment Station. The study which was begun in 1931 has been continued with rats on the stock regimen then described and with other rats on the Bills modification (Abst. 223, Vol. 1) of the Steenbock stock diet.

On the old stock diet the percentage of fertile matings and the percentage of young weaned declined gradually from 93 and 90 to about 80 and 82, but the weaning weights of the young increased slightly. On the Bills diet fertility declined only from 74.9 to 73.1 per cent., but the drop in percentage of young weaned, from 89.2 to 80.9, resembled that on the old stock diet. Weaning weights were better on the stock diet, but after weaning rats consistently became heavier on the Bills diet. The adult rats were heavier on the latter, but nursing females lost weight on it and maintained weight on the stock diet.

UGALDE, F., EGAÑA, E. and FALAHA, F. Algunos aspectos del ayuno experimental: su recuperación por elección alimenticia libre. [Some aspects of experimental fasting: recuperation on a freely chosen diet.] *Rev. méd. Chile*, 1954, **82**, 386-394. [Inst. Med. Exp., Esc. Med., Univ. Chile.]

Of 160 adult rats subjected to complete fast, except for water, 110 were killed after $6\frac{1}{2}$ days and the rest were allowed to recuperate, with free choice of diet. Clinical recovery was rapid; the animals reached an average weight of 262 g. in 14 days, after the initial weight of 253 g. had fallen to 186 g. during fasting. The changes of bodyweight did not directly reflect the weight changes of the different organs. The weights of brain and heart were unaffected by fast and recuperation. The weights of lung, liver, spleen and kidney were considerably diminished below normal values by fasting, and the spleen remained somewhat below normal after recuperation, though the other 3 organs reached values above normal. The adrenals showed hypertrophy as the result of fasting, but normal weights in the recuperated animals. Data are given for the effect of fasting and recuperation on the alkali reserve, basal metabolism, urinary and blood pictures, and fat content of liver, with metabolic studies *in vitro* with Warburg's apparatus, and histopathological studies of liver and kidney. There was pronounced fatty infiltration of the liver after recuperation, and in the fasting kidney a degenerative lesion of the tubules.—M. B. Richards.

LEE, M. F., HENRY, J. P. and BALLINGER, E. R. Basic requirements for survival of mice in a sealed atmosphere. *J. Aviation Med.*, 1954, **25**, 399-406; 432. [Aero Med. Lab., Wright-Patterson Air Force Base, Ohio.]

With a view to the eventual possibility of studying the biological effect of prolonged removal of gravity in a rocket satellite of the earth, experiments were made to ascertain the requirements for survival of mice in a sealed atmosphere.

N.A. and R., April 1955

A bell jar apparatus, illustrated and described, was developed with a living space of 13×26 cm. in which a mouse could survive for 30 days if supplied with 72,000 c.c. oxygen, 1300 g. soda lime to absorb CO_2 and water, 150 ml. water, and 200 g. Purina chow, of which 120 g. was eaten and the rest scattered. The rate of growth of such mice was similar to that of mice kept under similar conditions except that the bell jar was left open, or in open cages.—W. M. Deans.

2515

VAN REEN, R. and PEARSON, P. B. **Nutritional studies with the white-throated wood rat (*Neotoma mexicana*)**. *Science*, 1954, **120**, 571-573. [McCollum-Pratt Inst., Johns Hopkins Univ., Baltimore, Md.]

The wood rat is indigenous to the arid southwestern United States and Mexico. A commercial stock diet for rats appeared to be adequate for their maintenance and growth, but a purified diet was not accepted. They did not reproduce under laboratory conditions. Excretion of riboflavin, nicotinic acid and pantothenic acid were studied in animals on the stock diet.

The rats are not expected to be widely useful for laboratory experiments.—D. Duncan.

2516

TERLIZZI, L. **Dieta proteica esclusiva prevalentemente vegetale e resistenza massima al nuoto, nel ratto albino. [A diet exclusively of protein, chiefly vegetable, and maximum resistance to swimming by the albino rat.] Dieta proteica esclusiva, animale o mista, e resistenza massima al nuoto, nel ratto albino. [A diet exclusively of protein, from animal or mixed sources, and maximum resistance to swimming by the albino rat.]** *Bol. Soc. ital. Biol. sper.*, 1954, **30**, 23-25; 25-26. [Ist. Fisiol., Univ. Bari.]

Three male rats weighing from 90 to 100 g. were maintained on a diet consisting of 95 per cent. wheat gluten with salts and vitamins and 5 per cent. ovalbumin to supply amino-acids lacking from the wheat gluten. After 25, 30 and 35 days, respectively, they were made to swim carrying a 5-g. weight; exhaustion and death occurred in 42, 74 and 99 min.; for 3 rats fed normally the times were 161, 206 and 154 min.

The experiment was repeated with 3 rats fed normally and 3 maintained on a diet containing, per cent., casein 34, ox fibrin 53 and ovalbumin 13, with salts and vitamins. After 20, 25 and 30 days they were made to swim as described above and those on protein diet became exhausted in 123, 15 and 29 min., the times for the rats fed normally being 161, 144 and 144 min. When the

diet was of mixed animal and vegetable proteins, the times were 29, 89 and 120, with 161, 206 and 154 min. for normal rats.—E. M. Humc.

PICCIONI, M. **Azione di taluni antibiotici sullo sviluppo ponderale e sulla utilizzazione della quota proteica nel ratto. [Action of some antibiotics on weight gain and utilisation of protein in the rat.]** *Quad. Nutrizione*, 1953, **13**, 20-28. [Ist. Chim. Biol., Univ. Bologna.] French, English and German summaries.

Rats received to appetite, from weaning at 30 days, the diet of Randoin and Causseret (Abst. 3159, Vol. 17), with green food twice weekly; antibiotics were given daily in aqueous suspensions from a pipette. Groups of 10 males received daily 2.5 mg. aureomycin or terramycin or 5 mg. streptomycin; groups of 10 females received the same or 2.5 mg. chloramphenicol or 3 mg. penicillin. Controls of each sex had no antibiotic. The experiment lasted until the rats were 150 days old. Bodyweights were recorded, and faecal analyses were made after 15 days and at the end of the experiment.

The greatest effects of antibiotics on growth were in the first 15 days, during which terramycin, streptomycin and aureomycin increased the weight gain in both sexes by about 20 per cent. Chloramphenicol and penicillin were less effective. After 120 days the mean weights of treated groups were not more than 6.2 per cent. above those of controls and the differences were not significant. The faecal analyses showed that after 15 days the utilisation of dietary protein was improved by all the antibiotics. The improvement was about 24 per cent. with terramycin, aureomycin and chloramphenicol, 16 per cent. with streptomycin and 21 per cent. with penicillin. At the end of the experiment the first 3 antibiotics still gave 20 per cent. better utilisation than in controls, but the improvement with streptomycin or penicillin was no longer significant.—D. Duncan.

BERRY, M. E. and SCHUCK, C. **The effect of aureomycin on growth and protein utilization in the rat.** *J. Nutrition*, 1954, **54**, 271-284. [Dept. Foods Nutrit., Purdue Univ., Lafayette, Ind.]

Weanling rats were fed on diets containing casein, cottonseed meal or soya bean meal as sources of protein. Aureomycin at 10 mg. per 100 g. of a diet containing 15 per cent. protein as soya bean meal or cottonseed meal increased growth; when the diet contained 15 per cent. casein aureomycin was ineffective, but it increased growth on a diet with 9 per cent. casein. At 18 and 21 per cent. levels of cottonseed meal protein,

aureomycin increased weight gains by 34 and 19 per cent.

The addition of amino-acids to casein at the 9 per cent. level and soya bean and cottonseed meal proteins at the 15 per cent. level increased growth, which was further increased by aureomycin. This suggested that aureomycin acted in some other way besides making amino-acids available.

Aureomycin improved the apparent digestibility of cottonseed and soya bean meal proteins, but impaired utilisation followed. This was most pronounced with cottonseed meal.—A. Hepburn.

2519

FRENCH, C. E., URAM, J. A., INGRAM, R. H. and SWIFT, R. W. The effect of high levels of terramycin and streptomycin on longevity in the rat. *J. Nutrition*, 1954, **54**, 75-80. [Dept. Animal Nutrit., Pennsylvania State Univ., State College.]

Eighty-three male and 84 female rats were reared on a complete diet. At 11 months of age 51 males and 55 females received, during alternate months, either streptomycin sulphate or terramycin hydrochloride incorporated into the diet at 0.02 per cent.; 7 months later this was doubled. The other rats continued on the control diet throughout the experiment; food was given to appetite to all. About 10 rats of each sex from both groups were killed at intervals for histological study.

The addition of antibiotics to the diet decreased the average life span of both sexes by about 10 per cent. Neither beneficial nor deleterious effects were observed on the organs or on the incidence of chronic pneumonia.—G. F. Garton.

2520

REBER, E. F. and WILLIGAN, D. A. The effects of a chlorophyll derivative when included in a ration fed rats. 2. Reproduction, blood and tissue studies. *Amer. J. Vet. Res.*, 1954, **15**, 643-646. [Coll. Vet. Med., Univ. Illinois, Urbana.]

Rats were fed from weaning on a semi-synthetic diet and a group of 6 females received 1 per cent. of sodium potassium copper chlorophyllin in the diet. There was no adverse effect on growth, rate of conception or number of young born in the first litters of these females, but only 2 of the 6 litters survived to weaning at 21 days, and the mean weight of the young at this age was 30 g., against 40 g. in controls whose mothers received no chlorophyllin; after weaning the poor growth was partly compensated in 7 days of rapid gain. The young showed muscular weakness.

The rats given the chlorophyllin had significantly higher neutrophil counts and hence higher total white blood cell counts than controls. Poly-

chromasia and normoblasts were absent from blood smears of 4 of 5 animals given chlorophyllin.

The first generation young rats killed at 28 days of age after receiving the chlorophyllin had pale green, rough hair and greenish tissues. Some of the muscles were pale and showed selective degeneration and phagocytosis of fibres.—D. Duncan.

FINK, H. Zur Kenntnis der alimentären Lebernekrose der Ratte. [Dietary liver necrosis in the rat.] *Hoppe-Seyler's Ztschr.*, 1954, **298**, 93-96. [Inst. Gärungswissensch., Univ. Cologne.]

The findings by Fink *et al.* (*Hoppe-Seyler's Ztschr.*, 1953, **294**, 123) that rye and wheat in small amounts retarded the onset of liver necrosis in rats on a mushroom diet (*Anst.* 2073, Vol. 24) suggested a trial of the effect of omitting these cereals, which provided 15 per cent. of the total protein, from a non-necrogenic diet based on dried skimmed milk.

In experiments with different batches of milk and about 170 rats in all, initial growth was rapid, as good as in rats on the milk diet with cereals and much better than in those on the mushroom diet, but in the end mortality from liver necrosis, which generally set in after from 30 to 100 days, was about 80 per cent. Possible causes are indicated and work to elucidate them is in progress.

Neither egg protein nor the protein of unicellular algae (*Scenedesmus obliquus*) produced liver necrosis within 30 to 100 days.

The findings with milk and cereals are fresh evidence in favour of this combination of proteins and hence of the use of skimmed milk in bread-making.—W. M. Deans.

COBURN, A. F., GRAHAM, C. E. and HANINGER, J. The effect of egg yolk in diets on anaphylactic arthritis (passive Arthus phenomenon) in the guinea pig. *J. Exp. Med.*, 1954, **100**, 425-435. [Rheumatic Fever Res. Inst., Northwestern Univ. Med. Sch., Chicago, Ill.]

When egg yolk was added to the diet of pregnant guineapigs and to the diet of the offspring the young received a high degree of protection against anaphylactic arthritis. When egg yolk was given to weanling guineapigs for 3 to 5½ weeks a significant degree of protection was obtained also. The active material in egg yolk was in the alcohol-soluble fraction. The results are discussed in relation to the pathogenesis of rheumatic fever in children.—F. C. Aitken.

WAXLER, S. H. and ENGER, M. **Organ weights and obesity in mice.** *J. Nutrition*, 1954, **54**, 209-214. [Dept. Pharmacol., Stanford Univ. Sch. Med., San Francisco, Calif.]

Adult male mice were made obese by giving them a single injection of gold thioglucose and then allowing them unlimited food for 4 months. They weighed 46 to 55 g. and controls weighed 27 to 38 g. when they were killed, and separate organs were weighed wet, dry and defatted. On all 3 bases the liver, spleen, thymus and adrenals showed the greatest increases in obese animals; the increases were roughly proportional to the increase in bodyweight. The increases in kidney, testes and brain were negligible, those in heart, lung and femur somewhat greater.

In a group of mice made obese by the same method and then brought down to control weight by food restriction the organ weights were similar to those of controls and sometimes less.—D. Duncan.

2525

MARSHALL, N. B. and MAYER, J. **Energy balance in goldthioglucose obesity.** *Amer. J. Physiol.*, 1954, **178**, 271-274. [Dept. Nutrit., Harvard Sch. Pub. Health, Boston, Mass.]

Gold thiomalate or sodium thioglucose when used to provide amounts of gold and thioglucose equivalent to those which, in the form of gold-thioglucose, gave rise to obesity in mice, produced no obesity. In metabolism studies the food intake by obese mice was 8.0 g. and by non-obese control animals 4.9 g. daily. Total activities in terms of revolutions of activity cages were 541 and 928 and basal oxygen consumption rates were equivalent to 11.5 and 8.5 Cal. daily for obese and control mice.

Feeding experiments were also made with 3 diets, carbohydrate-, fat- or protein-rich with 64, 75 and 69 per cent. of their energy derived from these respective nutrients. Over 19 days average gains on the first 2 diets were 2.0 and 6.6 g. per animal, but on the high-protein diet there was an average loss of 6.2 g. per animal.

The results are compared with those of an earlier study (Abst. 4535, Vol. 23) and are concluded to provide additional evidence of the multiple etiology of obesity.—D. Harvey.

SHAW, J. H. An effect of certain nutritionally inert materials on the incidence of experimental dental caries. *J. Nutrition*, 1954, **54**, 177-191. [Harvard Sch. Dent. Med., Boston, Mass.]

Data are reported from 5 experiments with cotton rats and desalinated white rats: (1) with 69 cotton rats of a strain susceptible to caries and given a caries-producing diet, No. 100, alone or with additions of agar or cellulose flour; (2) with 23 white rats given diet 100 alone or with cellulose flour; (3) with 55 white rats given diet 100 alone or with 20 per cent. polyvinyl acetate of low molecular weight in either of 2 forms (L-PVA); (4) with 38 white rats given diet 100 alone or with 5, 10 or 20 per cent. L-PVA; (5) with 46 rats given a similar

basal diet alone or with the same L-PVA, a comparable polyvinyl acetate of high molecular weight, the natural rubber derivative chicle, or arochem, an esterification polymer of glycerol, fatty acids and rosin. The numbers and extent of carious molars and lesions were recorded.

Experiments 1 and 2 showed that the increase in mastication occasioned by a simple increase in the quantity of the diet required by the rats to maintain their growth was without effect on the carious lesions. Experiments 3, 4 and 5 indicated that the L-PVA greatly reduced the incidence of caries and that the other materials in the fifth experiment did so also but to a slightly less extent. There was again no evidence that the amount of mastication affected the incidence of caries.

GENERAL METABOLISM AND FEEDING HABITS OF ANIMALS OTHER THAN MAMMALS AND BIRDS

2536

KHARIN, N. N. and TASHCHILIN, V. A. Pitanie utok i ikh vozmozhnoe vozdeistvie na formirovanie vodnykh biotenzozov. [The nutrition of ducks and their possible effect on the formation of aquatic biocoenoses.] *Zool. Zh.*, 1953, **32**, 1251-1258. [Dept. Zool., Novocherkassk Zoovet. Inst.]

The object of the investigation was to discover whether ducks on fishponds consumed some of the food essential to the fishes' development. The ducks' diet was analysed by means of a oesophageal fistula, the duck being allowed to forage for 15 to 25 min. daily over a period of 3 months.

From the amounts of different foods consumed it is concluded that when ducks are present in large numbers on fishponds, particularly shallow ones, they could have a depressing effect on *Daphnia* and similar organisms, which are important fish foods.—H. Scherbatoff.

IRISAWA, H. and IRISAWA, A. F. Blood serum protein of the marine Elasmobranchii. *Science*, 1954, **120**, 849-851. [Dept. Physiol., Sch. Med., Univ. Hiroshima, Kure, Japan.]

Paper electrophoresis of serum proteins of skate and shark showed patterns different from those of other animals. The fastest component was not albumin, which is apparently absent.—A. Hepburn.

2538

ROBERTSON, J. D. The chemical composition of the blood of some aquatic chordates, including members of the Tunicata, Cyclostomata and

Osteichthyes. *J. Exp. Biol.*, 1954, **31**, 424-442. [Dept. Zool., Univ. Glasgow.]

Tunicates studied were the ascidian *Phallusia mammillata* and the thaliacean *Salpa maxima* in both its asexual solitary and its sexual chain form. The concentrations in plasma, expressed as a percentage of those in sea water, were for the ascidian Na 99.4, K 100.2, Ca 93.3, Mg 98.8, Cl 103.6 and SO₄ 52.5; for the 2 forms of thaliacean Na 100.3 and 100.8, K 112.9 and 114.3, Ca 95.9 and 95.0, Mg 94.9 and 95.4, Cl 102.4 and 102.5 and SO₄ 64.9 and 67.2.

The Cyclostomata studied were the hagfish, *Myxine glutinosa*, and the lamprey, *Lampetra fluviatilis*. In serum from 3 specimens of hagfish the mean amounts, in m. equiv. per kg. water, were Na 558, K 9.6, Ca 12.5, Mg 38.8, Cl 576, SO₄ 13.3, cations 619 and anions 602. In lamprey plasma corresponding values were 119.6, 3.21, 3.93, 4.21, 95.9, 5.44, 131.3 and 120.5.

The bony fish studied were the Roman conger, *Muraena helena*, and the freshwater whitefish, *Coregonus clupeoides*, for both of which plasma was analysed. In m. equiv. per kg. water values for the conger were Na 211.8, K 1.95, Ca 7.73, Mg 4.85, Cl 188.4, SO₄ 11.35, cations 228.4 and anions 217.4. In the *Coregonus* plasma corresponding values were 140.9, 3.81, 5.34, 3.38, 116.8, 4.58, 153.8 and 140.6.

The Tunicates, though without excretory tubules, show some ionic regulation, especially in the low SO₄ levels. The amount of protein is small, less than 1 g. per litre plasma. In the serum of the hagfish each ion is regulated, Na and PO₄ being higher and the others, especially SO₄ and Mg, lower than in sea water. The plasma of the fresh

N.A. and R., April 1955

water lamprey resembles that of the teleost *Coregonus*. In the marine teleost *Muraena* the total concentrations of cations and anions are 31 and 30 per cent., respectively, of those in sea water; the concentrations of Na and Cl are much higher than in the freshwater teleost.

The evolutionary implications of the findings are discussed.—D. Harvey.

2539

POTTS, W. T. W. The inorganic composition of the blood of *Mytilus edulis* and *Anodonta cygnea*. *J. Exp. Biol.*, 1954, **31**, 376-385. [Dept. Zool., Univ. Cambridge.]

From analyses for Na, K, Ca, Mg, Cl, SO_4 and CO_2 in samples of blood of the marine mussel, *Mytilus edulis*, values of 11.54, 0.497, 0.505, 1.357, 20.78, 2.944 and 0.220 mg. per g. water, respectively, were obtained. Corresponding values for samples from the freshwater mussel, *Anodonta cygnea*, were 0.358, 0.019, 0.337, 0.00465, 0.415, 0.073 and 0.643 mg. *Mytilus* blood resembles sea water in composition, but the concentrations of Ca, K and CO_2 are higher than those in sea water, 0.445, 0.420 and 0.111 mg. per g., respectively.

Calculation of the ratios of the values for *Mytilus* to those for *Anodonta* blood showed that Ca and CO_2 concentrations in the 2 bloods were of the same order of magnitude and from consideration of the solubilities of the 2 crystalline forms of CaCO_3 , calcite and aragonite, it is concluded that in each species the blood is saturated with respect to aragonite.—D. Harvey.

2540

SILVERMAN, P. H. and LEVINSON, Z. H. Lipid requirements of the larva of the housefly *Musca vicina* (Macq.) reared under non-aseptic conditions. *Biochem. J.*, 1954, **58**, 291-294. [Med. Res. Labs., Med. Corps, Israel Defence Army.]

Batches of 20 to 25 eggs of the fly, each contained in 1 ml. of a suspension of bacteria (mainly *Bact. coli*) normally found in the gut of the insect, were incubated at 35°C. in wet media. The media consisted of (1) whole wheat bran (control), (2) lipid-free bran, (3) lipid-free bran plus the lipids extracted from bran, (4) lipid-free bran plus 1 per cent. yeast extract, (5) lipid-free bran plus 1 per cent. saponifiable bran lipids, (6) lipid-free bran plus 0.17 per cent. unsaponifiable matter of bran, and 8 more diets consisting of diet 4 plus 1 per cent. saponifiable wheat bran lipids or 0.17 per cent. of one of the following: unsaponifiable wheat bran lipids, wheat bran sterols, sitosterol, cholesteryl, cholesteryl acetate, cholest-4-en-3-one and cholestan-3-one. One test tube from the 7 used for each diet was opened for examination before the time of pupation; when pupation

occurred, on the fifth to seventh day, the remaining tubes were opened and the pupae were pooled for weighing. The number and average weight of larvae was noted daily; growth curves were constructed.

The only lipid required by the larvae was contained in the sterol fraction of the wheat bran diet and identified as sitosterol; the same biological activity was produced by cholesterol, cholesteryl acetate and cholest-4-en-3-one. Cholestan-3-one could not replace cholesterol and behaved as an inhibitor of growth and pupation.

The role of sitosterol in larval resistance to bacterial infection and in the promotion of growth and pupation is discussed.—G. A. Garton.

2541

LEVINSON, Z. H. and SILVERMAN, P. H. Studies on the lipids of *Musca vicina* (Macq.) during growth and metamorphosis. *Biochem. J.*, 1954, **58**, 294-297. [Med. Res. Labs., Med. Corps, Israel Defence Army.]

(See also previous abstract.)

The water and lipid content of batches of eggs, early and late third stage larvae, immature and mature pupae and the newly-emerged adult fly were estimated; similar studies were made on the puparia, media before rearing, media with bacteria after rearing larvae and media after culturing only bacterial flora.

The lipid content of *M. vicina* rose in 7 days from 2.5 µg. in the egg to 1225 µg. in the late third stage larva; within 24 hr. of the onset of pupation it fell to 880 µg. The 2-day-old pupa contained 714 µg. lipid of which, 48 hr. later, 294 µg. was recovered from the emergent fly and 22 µg. from the puparium. No appreciable change occurred in the saponification number (216.8 to 219.1) of the lipid during larval growth and pupation; the saponification number (225.0) of the newly emerged fly suggests that it contains a significantly higher proportion of shorter-chain fatty acids. Throughout growth and metamorphosis the amounts of sterols and unsaponifiable lipids (4 to 5 per cent. of total lipids) remained relatively constant. As judged by iodine value the fatty acids of the wheat bran diet are laid down during larval growth in their unsaturated state, saturation or decomposition into shorter-chain acids beginning with the onset of pupation.—G. A. Garton.

NOLAND, J. L. Sterol metabolism in insects. 2. Inhibition of cholesterol utilization by structural analogs. *Arch. Biochem. Biophys.*, 1954, **52**, 323-330. [Med. Labs., Army Chem. Centre, Md.]

For the previous study see Abst. 5061, Vol. 24. Growth response of nymphs of the cockroach

Blatella germanica was measured by the average weight of each diet group at 30 days of age or by the average age at which maturation occurred. The insects were fed on diets containing 0.05 per cent. cholesterol and 1 per cent. of each of a series of 31 cholesterol derivatives.

Thiocholesteryl acetate, cholesteryl chloride, cholesteryl methoxide and thiocholesterol were potent inhibitors of growth; weak inhibitors included Δ^2 -cholestene, cholesteryl alkyl phosphonate, cholesteryl thiocyanate and cholesterylamine. It is suggested that inhibition of cholesterol utilisation may be due to a competitive inhibition of cholesterol esterase during cholesterol absorption.—G. A. Garton.

5. HUMAN DIET IN RELATION TO HEALTH AND DISEASE

DIET

REQUIREMENTS

2547

Recommended dietary allowances for Australia. *Med. J. Austral.*, 1954, 113-114.

Energy allowances are based on the theoretical requirements of reference adults. The reference adults live in the warm temperate zone at a mean external annual temperature of 18° C. and their daily activity follows a typical Australian pattern. Allowances of vitamin B₁, and nicotinic acid are 0.5 mg. and 5.0 mg. per 1000 Cal., respectively. Daily protein allowances are 1 g. per kg. body-weight for adults, 1.5 to 3.0 g. per kg. for children and young adolescents and 3.5 g. per kg. for infants. Precise allowances of Fe are not considered to be justifiable. Ca allowances are 0.8 g. per day for adults, 1.5 and 2.0 g. for pregnant and lactating women, 0.6 to 1.0 g. for infants and 1.0 to 1.4 g. for children and young adolescents. Allowances of vitamin A, 5000 I.U. for adults and adolescents, 3000 for children, 6000 and 8000, respectively, for pregnant and lactating women, are based on the assumption that one-third is derived from preformed vitamin A and two-thirds from carotene. The vitamin A allowance of 1500 I.U. for infants is supposed to be derived entirely from preformed vitamin A. Allowances of ascorbic

acid are 30 mg. daily for adults, infants and children, 50 mg. for adolescents, 80 and 100 mg., respectively, for pregnant and lactating women. Recommendations for riboflavin are 1.6 mg. for adult men, 1.4 for women, increased to 1.8 and 2.0 during pregnancy and lactation, 0.9 to 1.7 for infants and children and 1.8 for adolescents. An allowance of 400 I.U. vitamin D is recommended for pregnant and lactating women and for all young people.

LIENDO COLL, P. and BENGIOA, J. M. Necesidades calóricas de la población venezolana. [Energy requirements of the population of Venezuela.] *Arch. venezol. Nutrición*, 1954, 5, 39-59. [Inst. Nac. Nutrición.] English and German summaries.

A study was made of the energy requirement of the Venezuelan people, on the basis of FAO recommendations (see p. 517, Vol. 20). Taking climate into account it was found to be 2136 Cal. per person daily. For the purposes of the study the weights of a man and a woman of 25 years of age were taken as 60 and 50 kg., respectively. These data were obtained from preliminary findings in a survey in Venezuela of more than 30,000 adults. From studies of energy consumption

N.A. and R., April 1955

based on retail purchases an allowance of 15 per cent. is made, which brings the gross daily requirement to approximately 2460 Cal.—M. B. Richards.

FEEDING OF INFANTS AND CHILDREN

2549

GOLDBLOOM, A. The evolution of the concepts of infant feeding. *Arch. Dis. Childhood*, 1954, 29, 385-390. [Dept. Paediat., McGill Univ., Montreal.]

2550

HYTTEN, F. E. Clinical and chemical studies in human lactation. 9. Breast-feeding in hospital. *Brit. Med. J.*, 1954, ii, 1447-1452. [Dept. Midwifery, Univ. Aberdeen.]

For Parts 7 and 8 see Absts. 983 and 2449 Vol. 25.

Of 6456 women delivered of a single infant which survived the lying-in period, 84.5 per cent. left hospital fully breast feeding. The most important single cause of failure of infants to leave hospital fully breast-fed was poor lactation, 39.4 per cent. of all failures. Separation of the mother and baby in hospital, usually because of prematurity, refusal of the mother to breast feed and anatomically poor development of nipples accounted for 16.6, 14.7 and 10.5 per cent., respectively, of failures. Other causes with their incidences were: sore and cracked nipples 6 per cent.; the baby being a poor feeder 5.6 per cent.; serious disease of the mother 5.8 per cent., and engorgement of breasts and mastitis 1.4 per cent.

The results were analysed in terms of parity, age, height, physical grade, social class, type of delivery and occurrence of pre-eclamptic toxæmia. There was a highly significant negative correlation between maternal age and success in breast feeding in hospital, and a highly significant positive correlation between physical grade and breast feeding performance. The performance of tall women was better than that of small women. Operative delivery and moderate or severe eclampsia were associated with poor performance.

F. C. Aitken.

CAMPBELL, W. A. B. and CHEESEMAN, E. A. Breast feeding in Co. Armagh and Belfast: an attempted comparison. *Med. Officer*, 1954, 92, 251-252. [Royal Maternity Hosp., Belfast.]

The incidence of breast feeding among 138 infants born in 3 areas in County Armagh was lower at all ages, though not always significantly so, than in 500 infants born in Belfast during the same quarter (Abst. 5077, Vol. 24), and this was

Vol. 25, No. 2

still true when group differences in age of mother, parity, type of antenatal care and place of confinement were allowed for.—W. M. Deans.

2552

KALLIALA, H., HALLMAN, N. and TUUTERI, L. Amningsfrekvensen i Helsingfors under de senaste åren. [Frequency of breast feeding in Helsinki in recent years.] *Nord. Med.*, 1954, 52, 1579-1582. [Barnklin., Univ. Helsinki.] English summary.

This analysis was prepared from records collected by public health nurses in welfare centres. The frequency and duration of breast feeding have declined in comparison with earlier data. In detail, frequency of suckling for 4 months or more rises with age of mother but not with parity; it is not related to help in the home or to outside work but shows some inverse relation to crowding, in terms of persons per room. The main cause of the decline is thought to be the belief that breast feeding is not practised in "advanced" countries such as the United States.—I. Leitch.

DOUGLAS, J. W. B. Birth-weight and the history of breast-feeding. *Lancet*, 1954, 267, 685-688. [Dept. Pub. Health, Univ. Edinburgh.]

The conclusion drawn in this paper was reached incidentally during the "long-term study of child health" which is an extension of the 1946 maternity survey. Data for breast feeding in that investigation were reported in Abst. 4050, Vol. 20. During their later visits after 2 years to the survey children health visitors obtained data on the length of breast feeding and birthweights for these original children and for subsequent children born to the same mothers.

The proportion of babies whose birthweight was less than 6 pounds, born to multiparae, is inversely related to the length of time their previous babies were breast fed. This relationship was found within maternal social class and age groups and was independent of the birth order of the child, its sex, the birthweight of the previous child or the interval between births.

No reason for the finding is suggested.

SALBER, E. and BRADSHAW, E. The effect of birth weight and time of first feed on the weight of Bantu babies in the first 10 days of life. *Human Biol.*, 1954, 26, 156-171. [Inst. Family Community Health, Durban.]

Of 598 infants for whom records have already been published (see Abst. 910, Vol. 24) birthweights of 596 and time of first feed for 577 were known. Daily weight changes were recorded. They were

grouped as light, 5 lb. 8 oz. to 6 lb. 7 oz., average, 6 lb. 8 oz. to 7 lb. 15 oz., or heavy, above 8 lb. at birth, and as early, middle or late feeders according as first feeding was within 1 hr. of birth, from 1 to 6 hr. or more than 6 hr. after birth.

Heavier babies lost more weight than lighter and generally for a longer period. At time of discharge from hospital those with heavy birth-weights remained heaviest. The time of first feeding had a greater effect on progress than had birthweight. Of firstborn babies, late feeding girls and middle feeding boys lost less weight and middle feeders of both sexes returned to birthweight sooner than those in other groups. Of subsequent infants, middle feeding girls and early feeding boys had smallest losses and returned to birthweight soonest.

The evidence was that subsequent babies could be fed earlier than firstborn and boys earlier than girls. Except for firstborn girls, results were best when infants were fed within 6 hr. of birth.

HYTTEN, F. E. and MACQUEEN, I. A. G. **Artificial feeding and energy requirements of young infants.** *Lancet*, 1954, 267, 836-839. [Dept. Midwifery, Univ. Aberdeen.]

Mothers using national dried milk for feeding infants are supplied with a measuring scoop and directed to level off a scoopful of powder with a knife. Analyses of feeds made in the laboratory according to the instructions on quantity which are printed on the labels showed that with both half-cream and full-cream milk the theoretical energy requirements of infants were not met. If the scoop was tightly packed with powder, feeds from full-cream milk but not from half-cream milk met the theoretical energy requirements.

One hundred samples of feeds made at home by mothers were analysed. Of these 73 were made of national dried milk. The infants were classified according to general health and well-being and the competence of the mothers was graded subjectively. Sixty-nine infants were receiving less than their theoretical requirement of 120 Cal. per kg. expected bodyweight and 49 were receiving less than 100 Cal. Babies on the higher energy intakes were healthier and gained more weight than those on low energy intakes. There was a considerable degree of underfeeding in all competence groups.

It is suggested that the instructions issued to mothers for the preparation of artificial milk mixtures should be revised and that, if partly skimmed dried milk is required for the special use of premature or sick babies, it should be available only on prescription.—F. C. Aitken.

WICHERT, K. H. Ernährung von Frühgeborenen mit evaporierter, homogenisierter Milch. [Feeding premature infants with evaporated homogenised milk.] *Monatsschr. Kinderheilk.*, 1954, 102, 295-299. [Altona Kinderkrankenhaus von 1859, Hamburg.]

As supplement to breast milk, a buttermilk preparation or a mixture of evaporated homogenised milk with 5 per cent. sugar was given to alternate premature infants, 40 having evaporated milk and 39 buttermilk. The results are grouped according to birthweight; the average daily weight gain was 23.6 g. with evaporated milk and 21.0 g. with buttermilk. Both were well tolerated and no significant difference was found between the groups in the number of digestive disturbances or infections. The evaporated milk mixture was easy to prepare and less expensive than the buttermilk preparation. Wider trials of evaporated homogenised milk for premature infants are advocated.—A. M. Copping.

PERES, E. Kondensmilch (evaporierter Milch) als Säuglingsnahrung. [Condensed (evaporated) milk as food for infants.] *Münch. med. Wochenschr.*, 1954, 96, 920-922. [Kinderabt., Marienhosp., Düsseldorf.]

Unsweetened evaporated milk (Libby), diluted to equal whole milk, two-thirds milk or half milk, was used for feeding 54 infants with digestive or other illness and 17 premature infants. For all of them the milk proved highly satisfactory. Its wider use for infants is recommended.

A. M. Copping.

VIGNEC, A. J. and JULIA, J. F. **Honey in infant feeding.** *Amer. J. Dis. Child.*, 1954, 88, 443-451. [Dept. Paediat., New York Foundling Hosp.]

In an institution 3 groups of infants under 4 months, 387 in all, were fed on isocaloric mixtures of evaporated milk and water with 5 per cent. of light clover honey, Dextri-Maltose No. 1, or Karo [not described].

Most infants readily took the feeds with honey. Gains in weight and length were as good as with Dextri-Maltose and better than with Karo. For Hb value and red cell count, honey was better than Karo but not quite so good as Dextri-Maltose. For incidence of non-specific gastro-enteritis and other feeding problems, honey and Dextri-Maltose were much the same, and superior to Karo.

It is concluded that honey has a definite place in infant feeding.—W. M. Deans.

WIDDOWSON, E. M. and McCANCE, R. A. Studies on the nutritive value of bread and on the effect of variations in the extraction rate of flour on the growth of undernourished children. *Med. Res. Council. Spec. Rep. Ser.* No. 287, 1954, pp. viii + 137. H.M.S.O., London. Price 8s. 6d. net.

The subjects of the experiment were orphanage children, 169 at Duisburg and 141 at Vohwinkel. At Duisburg they were divided into 5 closely matched groups. They were given all of the non-cereal portion of the German rations to which they were entitled and each group had unlimited amounts of bread baked from one of 5 experimental flours: 100, 85 or 70 per cent. extraction; or 70 per cent. extraction enriched with vitamin B₁, riboflavin, nicotinic acid and Fe to one of 2 levels, those in 100 per cent. and in 85 per cent. extraction flour. All 5 flours contained added Ca. These experimental breads provided over 70 per cent. of the total energy. At Vohwinkel 3 flours were tested, 100 or 70 per cent. extraction and 70 per cent. enriched to 100 per cent. levels. Here unlimited amounts of fat, sugar and jam were allowed with the flour so that the children obtained 35 per cent. of their energy from flour and 35 per cent. from the other supplements. In this orphanage the flour was baked into bread, cake and biscuits. All children in the experiment were given vitamin A, D and C tablets daily. The experiment lasted 1 year; at Duisburg 105 children completed the year and at Vohwinkel 55. They were weighed and measured every fortnight and examined clinically every 3 months. Studies of intakes and excretions of N, minerals and vitamins of the B complex were made at intervals on some of the children.

From an analysis of the results of the experiment no difference could be detected between the nutritive value of the different breads and all the children did remarkably well on the diets.

In a supplementary 6-month experiment the daily addition of 500 ml. whole milk reconstituted from dried milk to the Duisburg experimental diet with 85 per cent. extraction flour did not improve growth rate over that of control children given an equicaloric supplement of biscuit made of flour, sugar and margarine and a drink of orange juice.

The nutritive values of the 100 and 70 per cent. extraction flours were compared in rat and pig feeding trials. Diets were similar to those consumed by the children. When rats were given the diets from 8 weeks of age the flours were equally good as measured by growth; when the

diets were given from weaning the wholemeal flour was superior to the white. When 11-week-old pigs were given these flours in diets of the Vohwinkel type wholemeal flour produced slightly more rapid gains in weight than did white flour. This difference was not evident when the diet was of the Duisburg type with 75 per cent. of the energy from flour.

A statistical analysis of the height and weight data and detailed reports on metabolism studies, skeletal development and dental caries in the children are given in appendixes.—F. C. Aitken.

SUBRAHMANYAN, V., REDDY, S. K., MOORJANI, M. N., SUR, G., DORAISWAMY, T. R., SANKARAN, A. N., BHATIA, D. S. and SWAMINATHAN, M. Supplementary value of vegetable-milk curds in the diet of children. *Brit. J. Nutrition*, 1954, **8**, 348-352. [Central Food Technol. Res. Inst., Mysore.]

The preparation from groundnut kernels is described of a product which, when mixed with a small amount of buttermilk, sets to form a curd much the same as does cow's milk. It is fortified with minerals and vitamins. The composition of the final product is given in terms of 14 nutrients and compared with that of cow's milk curd.

Forty-two girls aged between 4 and 11 years and living in a boarding home were the subjects of experiment; half received 12 oz. daily of the vegetable curd and half were kept as controls and given sweetened pudding to provide an equivalent amount of energy. Height, weight, Hb, red cell count and nutritional deficiency score were studied over 6 months. Changes which, statistically, were highly significant were found to have occurred in growth and in the nutritional score in favour of those girls who ate the vegetable-milk curd.

SUBRAHMANYAN, V., SWAMINATHAN, M., BHATIA, D. S., BAINS, G. S., SUR, G., BHAGWAN, R. K., DORAISWAMY, T. R., ANANDASWAMY, B. and SANKARAN, A. N. Effect of replacing rice in the diet by composite *jowar* (*Sorghum vulgare*) vermicelli on the health and nutritional status of children. *Bull. Central Food Technol. Res. Inst. Mysore*, 1954, **3**, 245-247.

The preparation of a vermicelli type of food containing *Sorghum vulgare*, wheat and tapioca flours in the proportion of 2:1:1 is briefly described. The effects were studied of replacing rice by an equal amount of it in the diet of 21 children in a boarding home, with the same number of children as control subjects. The experiment lasted for 8 weeks and data for changes in height, weight and nutritional status are tabulated. The average increases in weight were 1.53 and

0.45 lb. for the experimental and control groups, respectively; the difference was highly significant. There was also evidence of improvement in nutritional status in favour of the experimental group.

D. Harvey.

SUBRAHMANYAN, V., DORAISWAMY, T. R., SWAMINATHAN, M. and SANKARAN, A. N. **Large-scale feeding experiments with Mysore flour in distress areas of Madras State.** *Bull. Central Food Technol. Res. Inst. Mysore*, 1954, **3**, 267-269.

Mysore flour is a mixture of 3 parts tapioca flour and 1 part groundnut flour (see Abst. 5086, Vol. 24). A large-scale feeding experiment was made to find to what extent this readily available food could replace cereals in the normal poor vegetarian diet in Madras. The experiment was made at 5 centres. The experimental diet is described, and a brief survey of the normal diet is reported. A table is given of the composition of experimental and normal gruels issued at the centres and shows that the experimental gruel was superior in energy, protein, vitamin B₁ and nicotinic acid.

At first, presumably because of prejudice, attendance at the centres fell considerably when the Mysore flour was introduced, but by the end of the experiment, which lasted 3½ months, attendance was nearly doubled and the Mysore gruel was relished. Measurements of height and weight of 181 children aged from 4 to 12 years were taken at one centre; they showed growth to be satisfactory on the experimental gruel.—T. D. Bell.

DIETARY SURVEYS AND INDIVIDUAL STUDIES

2564

TRULSON, M. F. **Assessment of dietary study methods. 1. Comparison of methods for obtaining data for clinical work.** *J. Amer. Dietetic Assoc.*, 1954, **30**, 991-995. [Dept. Nutrit., Harvard Sch. Pub. Health, Boston.]

Thirty-seven children aged 7 to 12, attending rheumatic fever clinics in Chicago, were studied (1) by 7-day diet records kept by the children themselves, (2) by detailed diet histories, and (3) by 24-hr. dietary recalls. In general, methods 1 and 2 gave results showing closest similarity, but the findings were by no means consistent when different foods or nutrients were considered. The data of Huenemann and Turner (Abst. 2536, Vol. 12) were used to show that the results of weighed surveys and diet histories are inconsistent.

THOMAS, R. U., FOX, H. M., KELLY, H. J., MOYER, E. Z. and MACY, I. G. **Rapid method for**

qualitative appraisal of food intakes of groups. Procedure and reliability. *J. Amer. Dietetic Assoc.*, 1954, **30**, 865-871. [Res. Lab., Child. Fund Michigan, Detroit.]

Diet patterns obtained mainly from pregnant women by the 7-day record or 24-hr. recall method were assessed in relation to an ideal dietary pattern designed to provide approximately the allowances of nutrients recommended by the U.S. National Research Council. The numbers of servings of important foods or food groups in the actual and reference diets were used to obtain scores which could be compared. The reliability of the scoring system was evaluated by comparison with laboratory analyses of diets, calculation of nutritive values from food composition tables, and diet ratings obtained from another laboratory. It is concluded that the qualitative assessments served to classify women into groups roughly according to their nutritional status.—A. M. Thomson.

2566

BEAL, V. A. **Nutritional intake of children. 2. Calcium, phosphorus and iron.** *J. Nutrition*, 1954, **53**, 499-510. [Child Res. Council, Denver, Colo.]

For part 1 see Abst. 1003, Vol. 24.

Data on the intake of Ca, P and Fe from 795 diet histories on 26 boys and 32 girls in the first 5 years of life are presented.

Ca intake increased rapidly in the first 6 months of life and less so between 6 and 9 months; it then fell steadily to reach its lowest level between 2 and 3 years, when the median for Ca intake was 0.75 g. and for milk intake 16 oz. This was followed by an increase and at 5 years the median intake was about 1 g. Ca. Between 6 and 15 months there was a sex difference in Ca intake, that of boys being the higher.

P intake, being less closely linked with milk consumption, showed less striking changes than Ca intake. It increased during the first year, then showed a pattern intermediate between those of protein and of Ca between 2 and 3 years and increased again between 3 and 4 years.

Fe intake increased greatly during the first year because of the high Fe content of commercial infant cereals and fell as these were replaced in the diet. After 3 years it again increased but between 2½ and 5 years of age more than three-quarters of the children studied had intakes below U.S. National Research Council recommended amounts.—G. F. Garton.

2567

BABCOCK, M. J., CHURCH, H. N. and GATES, L. O. **Nutritional status of industrial workers. 1. Dietary, blood, and physical findings.** *Milbank Mem. Fund Quarterly*, 1954, **32**, 323-342.

N.A. and R., April 1955

[New Jersey Agric. Exp. Stat., Rutgers Univ., New Brunswick.]

The subjects were 610 male industrial workers in New Jersey; the investigation was part of a more extensive study (see Absts. 3430, Vol. 23, 2265, Vol. 24, 2619, Vol. 25). The data were grouped in a variety of ways according to weight, general appearance of the subject, activity at work, income and educational levels, religion, ethnic group, diet, blood chemistry, a clinical examination and an overall rating of vitamin status. The diet study by the interview method was, for 318 men, supplemented by a 7-day record. Blood constituents studied were vitamin A, carotene, ascorbic acid and Hb and the clinical examination was of eyes, skin, lips, gums and tongue, thyroid gland and neurological signs. The overall vitamin rating was based on the 3 recordings of diet, blood constituents and clinical examination. All inquiries were made during the winter months.

Most of the men were under 40 years of age and 35, 48 and 17 per cent., respectively, were very active, active and sedentary at work. Weekly incomes per adult unit ranged from between \$5 and \$9 to between \$55 and \$64. American and Slavic groups accounted for 71 per cent. of the population.

Average energy intake in Cal. was 2988 for sedentary, 2915 for active and 3259 for very active subjects and the overall mean 3053 Cal. For the 318 who kept 7-day records corresponding figures were 2709, 2739, 2785 and 2746 Cal. The difference by the 2 methods persisted when the data for those studied by both methods were considered; it was thought to have been caused by a tendency to overestimation at the interviews and underestimation in the recording. The evidence was that about a quarter of the men were having less than their needs of Ca, P, vitamin B₁, riboflavin and ascorbic acid, a finding that could be attributed to their having too little milk and vegetables and fruit and too much unenriched bread and pastries, sweetened beverages and sweets. The parts played by education, age and income are to be the subject of a later communication.—D. Harvey.

2568

RODAHL, K. **Nutritional requirements in cold climates.** *J. Nutrition*, 1954, 53, 575-588. [Arctic Aeromed. Lab., Fairbanks, Alaska.]

Total daily food intake was measured during the 4 seasons from 1950 to 1952 in Alaska for 36 young infantrymen or airmen on ordinary duties and, for comparison, for 16 adult male Eskimos. Medical examinations and some laboratory tests were made for signs of deficiency.

The average daily energy intake was 3000 Cal. for the air force and 3200 for the infantry group; the average energy expenditure for the 4 seasons

was, on the basis of time activity data, 2800 Cal. daily. No appreciable weight change occurred and the subjects remained in excellent health. For the Eskimos, who came from 4 different localities in Alaska, the average daily energy intake was 3100 Cal.; this maintained bodyweight. Daily energy expenditure was 2700 Cal. throughout the year. In composition the diet of the troops in Alaska was not significantly different from that of U.S. troops stationed in temperate or tropical climates, but the air force group tended to eat more fat in the winter. The consumption of mineral salts was higher than the allowances recommended for temperate climates. There was no evidence of increase in vitamin requirements in Arctic climates.

It is concluded that the energy needs of normal men engaged in such activities under these climatic conditions are 3000 to 3500 Cal. per man daily at any season of the year.—G. F. Garton.

2569

FERGUSON, T. and PETTIGREW, M. G. **A study of 388 families living in old slum houses. A study of 718 slum families rehoused for upwards of ten years.** *Glasgow Med. J.*, 1954, 35, 169-182; 183-201. [Dept. Pub. Health, Univ. Glasgow.]

These were 2 simultaneous and complementary investigations intended to provide broad comparisons of the effects of rehousing, for periods of between 10 and 27 years, on the standard of living of an urban population. The inquiries were intensive and data were collected depicting the size and structure of the families, the state of their health, and condition of their homes and their economic circumstances.

On conditions likely to affect their nutrition it was not possible to obtain information on total income but there were made available data which could be relied on to give an estimate of the amount of housekeeping money. This tended, in general, to increase with the number of persons in the household, but not necessarily in proportion. For the 366 and 646 families in the respective groups which gave information households in which the amount was under 60s. numbered 31 in the first group, 23 with 1 person, 6 with 2 and 1 each with 4 and 6 persons; in the second group they numbered 55, 40 with 1 person, 9 with 2 and 3 each with 3 and 5 persons in the household.

For much smaller numbers of families in the groups, 80 and 174, respectively, information was available on the amount spent on food. Families with 4 to 6 persons numbered 50 and 94 and, of these, 13 and 16 spent less than 15s. per head per week on food. In the first group there were 12 families with 6 persons for which average expenditure was 14s. 4d. and in the second 20 families

with 8 persons and average expenditure 15s. 6d. per week. Irrespective of the size of the families none of the means for amounts spent per head per week was below 12s. 8½d., the average per head for a family of 5 quoted by Schulz (Abst. 2161, Vol. 23) as the cost at the time of a "human needs" dietary.

The average amounts spent on food appeared to be not unsatisfactory but, of both groups, it was said that the information was provided by the women who were probably the most intelligent and provident and that it threw no light on the kind of food being bought. The rehoused families were without doubt in a substantially better environment than were the slum families, but the general conclusion regarding their feeding habits was that they showed no improvement. "It is abundantly clear that many rehoused slum families require a great deal of help and encouragement to make the transition from the slums to a new life."—D. Harvey.

2570

BUREMA, L. De voeding in Nederland van de Middeleeuwen tot de Twintigste Eeuw. [Diet in the Netherlands from the middle ages to the twentieth century.] Thesis, Univ. Amsterdam, 1953, pp. 330. [Lab. Physiol. Chem., Univ. Amsterdam.] English summary.

This elaborate 300-page thesis has five main headings: the middle ages, the 16th, 17th, 18th and 19th centuries. It is illustrated with reproductions of paintings by old masters, mostly representing meals or distribution of food. The author, in his search for information about nutrition in the Netherlands before 1900 has read through an immense amount of literature, descriptions of travels and voyages, annual reports, stories and poems, historical and medical books and periodicals, accounts of institutions and private families. His references are given at the foot of the relevant pages, not listed together at the end of the thesis. There is a ten-page Dutch summary and a translation into English of this summary.

In the middle ages agriculture was already partly organised on a three-field rotation with barley, wheat, oats and rye as crops. For grain Holland was both store and market for other countries. Pigs were most widely kept; dairying was established; the market gardens of the monks and the gentry were already famed abroad. Fishing was well developed and herrings were cured as early as 1100. Poultry were so widely kept as to serve at times as currency for tax payments, and bees provided most of the sugar to be had. The habit of burning salt peat for salt was forbidden in 1515, a peculiar sort of soil erosion.

From there, century by century, the development of agriculture is traced and food habits are described. There is a recurrent history of famine caused by floods or other disasters, or by war. There are frequent mentions of dentists and remedies for toothache; scurvy and night-blindness were common in the 15th century and scurvy at least continued well into the 19th. In the 16th century urolithiasis and rickets were common. In the 17th and 18th century wealth and poverty increased side by side. Lithiasis was common in all classes, attributed by the author to deficiency of vitamin A. Beriberi in the Dutch East Indies was described for the first time in 1611.

There is some information on infant feeding from 1473 and on infant mortality. Cod liver oil was used to treat rickets in 1822.

There is here a great wealth of interesting material which could have made absorbing reading if it had been well presented. Unfortunately the presentation is confused and the tale full of repetitions, unresolved contradictions and omissions. Too much perhaps is made also of the deficient diet and sufferings of the common man and not enough of his achievements between 1400 and 1900.—M. Eddison.

2571

BOUCHE, A. Enquête sur les budgets familiaux par carnets de comptes annuels à Marseille (2). (octobre 1951-septembre 1952). [Study of family budgets in Marseilles by questionnaire on annual expenditure 2. (October 1951-September 1952).] Bull. Inst. nat. Hyg., Paris, 1954, 9, 772-815. [Sect. Nutrit., Inst. Nat. Hyg., Marseilles.]

For part 1 see Abst. 5106, Vol. 24.

Nearly three-quarters of this section relates to food; it consists of an elaborate analysis of monthly variations in expenditure on different foods in households of 3 social classes and a study of the relation between food expenditure and income for 51 families which stated their income. For foods other than the meat, fish and eggs group the rise of expenditure with income flattened at the income level of 50,000 fr. per month. At this level, too, expenditure on different foods as a percentage of income began to fall. The results are analysed also in terms of income per head and income per consumption unit.—W. M. Deans.

2572

ŠNAJDER, K. Ishrana i njen uticaj na biološku snagu stanovništva u Autonomnoj Kosovometohijskoj Oblasti. [Nutrition and its influence on the life of inhabitants of the Autonomous District of Kosovo-Metohija.] Zborn. Rad., Srpska Akad. Nauka, 1954, 28 (Inst. Nutrit.,

N.A. and R., April 1955

No. 2), pp. 42. [Inst. Nutrit., Serb. Acad. Sci., Belgrade.] French summary.

Diet surveys were made in 60 families, 29 Serbian and 31 Siptar. The energy intake ranged from 774 to 5142, mean 1919, Cal. per person daily; the average daily intakes per head were 50.8 g. total protein with 15.8 g. from animal sources, 36.6 g. fat and 336.7 g. carbohydrate supplying, respectively, 11, 17 and 72 per cent. of the energy. Of the families 7 per cent. had daily intakes below 1000 Cal. and, at the other extreme, 5 per cent. had more than 3000 Cal. per head.

For 56 of the families studied the population density was high, the area of cultivable land being 0.47 ha. (1.16 acre) per person; for 2562 families in other communes it was 0.44 ha. (1.09 acre). Except for wheat, between 60 and 75 per cent. of the food produced went for home consumption. The effects of these conditions on family size were, however, small. In 74 Serbian families the average number of persons was 6.95 and in 37 Siptar 8.76.

Growth of children in the district was studied by measurements of 239 boys and 60 girls. Boys were on the average 2.9 kg. lighter and 3.2 cm. shorter and girls 2.5 kg. lighter and 1.4 cm. shorter than the standard for Serbian children. For children it was also found that the admission rate to hospital was 22 per cent. higher and dispensary attendances 40 per cent. more frequent than for the whole of Yugoslavia. Among the provinces Kosovo-Metohija was second highest in its infant mortality rate.

Overcrowding was high and lighting of homes poor. Among 659 children with nutritional disorders rickets, with an incidence of 23.6 per cent., followed closely on pellagra in frequency. Although the district is situated in latitude between 42° and 43° N., local conditions of living are such as to maintain this high incidence of rickets.

The data are presented in 30 tables. [From summary.]—D. Harvey.

2573

MOSER, A. M. Use of food by farm families in the tobacco farming area of South Carolina. *S. Carolina Agric. Exp. Stat. Bull.* No. 402, March 1953, pp. 61.

An earlier report (see Abst. 4915, Vol. 23) dealt with a tobacco-growing as one of 3 farming areas studied in the South; it referred to both Virginia and South Carolina. The differences in food habits known to exist in these States prompted the present analysis of the data for South Carolina by themselves.

There were 149 families, white and negro, of average size 6.41 persons. In 27 of these, intakes of 9 nutrients were found to be satisfactory when compared with U.S. National Research Council

recommendations. For food the average quantities, in 11 groups, eaten in these households were taken as standards; the mean for all families exceeded that average for dried legumes only, equalled it for fats and oils and fell short of it for the other 9 food groups.

The percentages of families which were receiving less than 2/3 of the amounts of individual nutrients were, for vitamin B₁ 0, Fe and nicotinic acid 1, energy 2, protein 3, riboflavin 19, vitamin A 36, calcium 40 and vitamin C 42. Use of enriched wheat flour, bread and maize meal ensured supplies of vitamin B₁, Fe and nicotinic acid. The outstanding need was for greater use of milk throughout the year and for greater production and preservation of vegetables and fruit for use in winter months.

Data are fully tabulated.—D. Harvey.

WHITE, H. S., COLLAZOS, C., C., WHITE, P. L., HUENEMANN, R. L., BENITES, R., CASTELLANOS, A., BRAVO, Y., MOSCOSO, I. I., and DIESEL-DORFF, A. Dietary surveys in Peru. 2. Yurimaguas, a jungle town on the Hualaga River. *J. Amer. Dietetic Assoc.*, 1954, 30, 856-864. [Dept. Nutrit., Minist. Pub. Health, Lima, Peru.]

For Part 1 see Abst. 2269, Vol. 24.

Two diet surveys were made, one at the end of the rainy season, the other at the end of the dry season. Thirty-eight families were surveyed in the first and 33 of these repeated in the second survey. The method of study was the one-week weighing and inventory record. During the first survey 30 adolescents and 23 adult women, some pregnant or lactating, were examined for nutritional state. The diet studies showed that the nutrients in most inadequate supply were Ca, riboflavin and vitamin B₁. In typical diets plantains (*Musa paradisiaca*) contributed more than 70 per cent. of vitamin A, about one-third of ascorbic acid, vitamin B₁, riboflavin and total energy, about 15 per cent. of nicotinic acid and about 10 per cent. of Fe and protein. Cooking losses were not considered in the calculation of nutrient intakes, but a study in one home indicated a loss in cooked plantains of 50 per cent. or more of carotene and ascorbic acid.

The study of nutritional state showed that almost everyone had intestinal parasites and that anaemia was widespread.

Dental caries was common, muscular development was frequently poor and signs possibly related to nutritional deficiencies were common. The high incidence of those possibly related to vitamin A deficiency was surprising in view of the very high estimated intake of vitamin A. It is

suggested that plantain carotene may not have the equivalence of 1670 I.U. vitamin A per mg., the figure which was used in making the calculations of intake.—F. C. Aitken.

STRACUSS, W., SHATAN-HERZBERG, M. and BORTEN.

E. Nutritional survey in Israel. Second interim report—surveys of 1951 and 1952-3. Dept. Hyg., Hebrew Univ., Jerusalem, 1954, pp. 41.

A diet survey was made in 1952-53 of 124 families in Tel-Aviv and 60 in Jerusalem. Records were made by investigators who were allocated about 7 families and who visited them twice daily for 30 days. Hb was estimated also in 3187 persons and weights and heights were taken for 1508 adults and 742 children. This interim report gives comparisons with the earlier survey.

At the time of the second survey a number of foods were still rationed. Data for energy and 9 nutrients are fully tabulated with special reference to size of family and to the communities, Ashkenazim, Mizrahim, Sephardim and Yemenites, to which the families belonged. The outstanding change since 1950 was the considerable increase which had occurred in the amount of bread used; average amounts were 250 and 380 g. per person daily. This change was responsible for increases in intakes of total protein and Fe and, to some extent, of Ca and riboflavin. A decrease in meat consumption probably accounted for the smaller amount of nicotinic acid. Differences in vitamins A and C were seasonal, the earlier survey having been in summer, the later in winter. The need for both encouraging the drinking of milk and cheapening it is emphasised, and doubt is expressed about the advisability of importing wheat for bread instead of using locally grown cereals and potatoes.

The blood data, Hb estimations and red cell counts, showed that the levels in the Israeli population were lower than in England during the war and that it was among immigrant men and women and among housewives that the degree of anaemia was greatest. A difference in favour of the Jerusalem when compared with the Tel-Aviv families could not be explained. There was a downward gradient in Hb parallel with social status and with intake of animal protein.

Weight and height data are given in summary tables for the adults in the 4 communities and graphically for age for the children. Some values for serum protein are also included.

2576

CORCKHILL, N. L. Seasonal dietary change in a Sudan desert community. *J. Trop. Med. Hyg.*, 1954, 57, 257-269. [Sudan Med. Serv.]

Descriptions are given of the inhabitants of Abu Deleig in Northern Sudan, the conditions under which they live and the foods which they use. Pyralgia, a burning sensation of the extremities with associated pain in the epigastrium, has already been described. (See Absts. 1721, 2772, Vol. 4; 2596, 5700, Vol. 20.)

Diet studies were made in 1945 and 1946 of 5 families at 3 different seasons, after the peak period of heat, in the season of plenty and in the cold season when green foods, meat and milk are least plentiful. Calculations of dietary intakes were made also from data collected in 1933 for 16 women with severe pyralgia, 33 men in whom it was less severe and 34 men with no sign.

It is concluded that the syndrome is caused by the seasonal change which occurs in the ratio of animal to total protein in the diet; it appeared when the ratio was 1:20 but was not seen when the ratio was 1:10 or less. There is evidence too that an increase in the amount of millet beer drunk will reduce the incidence of the disease.

D. Harvey.

DE MEIRA, M. T. V. Contribuição para o conhecimento do estado de nutrição da população de Cabo Verde. Resultados, comentários, dum inquérito realizado na Ilha do Sal, em 1949. [State of nutrition of the people of Cape Verde. Results, discussed, of the survey made on Salt Island in 1949.] *An. Inst. Med. trop., Lisbon*, 1953, 10, 1199-1232. *Proc. English summary.*

In a study of the state of nutrition of the population of Salt Island nearly 200 children between the ages of 5 and 15 years were weighed and measured and diet surveys were made in 5 native families. From the measurements of height and weight regression equations were calculated. The graphs deviate somewhat from normal by showing a gradual inversion of the values for the 2 sexes. From the age of about 8 years the boys are slightly inferior to the girls, probably because the latter live under greater social protection.

The diet survey table gives the following averages for the daily consumption per head: Cal. 2416; carbohydrates 489.3, fats 34.8, animal protein, 5.0, vegetable protein 63.1 g., Ca 193, P 1277, Fe 21.9 mg., vitamin A 1843 I.U., vitamins B, 2.1, riboflavin 0.9, nicotinic acid 8.2, vitamin C 2.5 mg. and vitamin D 95 I.U. The obvious defects of the diet are readily explainable. According to the diet sheets all families ate maize, beans, sugar, coffee and salt; 3 families ate fish. Other additions in some families were olive oil, onion, lard, rice, and wheat bread. In no case was there mention of such foods as milk, eggs, meat, potato, butter, cheese or any kind of fruit. Normally the diet would include more animal protein since

N.A. and B., April 1955

stormy weather during the week of the inquiry accounted for the small consumption of fish. The deficiency of protective foods will always exist.

M. B. Richards.

2578

FRANÇA, C. S. Contribuição para o estudo do estado de nutrição da população de S. Tomé. 1. Inquéritos alimentares em aldeamentos indígenas. [State of nutrition of the population of São Tomé. 1. Diet surveys in native settlements.] *An. Inst. Med. trop., Lisbon*, 1953, 10, 1447-1458. English summary.

A three-day dietary survey was made on 15 families distributed in 3 groups in São Tomé, the groups varying in social grade and economic resources. Daily consumption per unit is tabulated for each group for calories, carbohydrates, fats, protein, animal and vegetable, Ca, P, Fe, vitamin A, vitamin B₁, riboflavin, nicotinic acid and vitamin C. It is concluded that, in general, not enough food was eaten. Protein was below requirement and, in one group, animal protein especially was deficient. Minerals were low, in particular Ca, with a large deviation from normal of the Ca:P ratio. Of the vitamins, only for vitamin A, provided by the palm oil in the diet, was the requirement approached. The diet of all groups was based on maize flour, bananas, dried fish and rice, but in the highest income group, where deficiencies were less marked, there was frequent reference to the consumption of bread, butter, coffee, sugar, condensed milk and fresh fish. The degree of deficiency differed from group to group according to habits, education, resources, locality and its proximity to a centre of population, but lack of purchasing power was the basic cause. Interrogation showed that there was a desire for such foods as eggs, milk, butter, cheese, fresh fish, meat and fruit, if only more money were available to purchase them.—M. B. Richards.

2579

RODRIGUES, F. C. A alimentação do indígena de Vilanculos. [Diet of the indigenous inhabitants of Vilanculos.] *An. Inst. Med. trop., Lisbon*, 1953, 10, 1129-1155. *Proc.* English summary.

The diet of the natives of Vilanculos in Mozambique is based on cereal flours, maize, sorghum and pearl millet. The cereals are very finely ground, with complete removal of bran and loss of minerals, proteins and vitamins. Beans and other legumes are eaten and green vegetables and fruits are used especially in periods of scarcity. Cassava and sweet potato are poor in protein but the latter provides considerable amounts of vitamins B₁ and B₂; groundnuts are a source of high quality protein. Consumption of meat is

irregular and scanty, supplies being obtained by hunting. Although the natives possess domestic fowls, these, because of certain prejudices and taboos, are not used for food, but are sold in order to purchase alcoholic drinks. On the coast fish are eaten, though not in large amounts, and molluscs and crustaceans as well, the latter being the chief source of animal protein. In certain regions snakes, lizards and turtles are eaten and, in the interior of the country, the larvae of insects. Water is scarce but alcoholic liquors abound, not only European wines bought when means permit, but also all kinds of drinks prepared from local fruits. In periods of scarcity consumption of such drinks increases, and the natives live almost exclusively on herbs and wild fruits and are in a state of almost permanent intoxication. The diet is obviously monotonous, unbalanced, too bulky, poor in animal products such as eggs and dairy produce and therefore, deficient in proteins and fats of animal origin. It is much the same for all ages, and there is, as a result, a high rate of infant mortality.

Measures recommended for improving the conditions are: an educative campaign to demonstrate the necessity for quality and balance of dietary components rather than for quantity and to combat primitive prejudices against the use of certain foods: campaigns for the improvement of agricultural methods and against alcoholism: the construction of granaries, wells and reservoirs: and the establishment of the natives, at present scattered over enormous areas, in settlements in the more fertile areas, where they would have better natural conditions, and better medical attention could be ensured.—M. B. Richards.

2580

DO AMARAL, R. F. and DA COSTA SARAIVA, A. S. P. A propósito da constituição física e da alimentação dos indígenas da Delegacia de Saúde de Nampula. [Physical condition and diet of indigenous inhabitants of the health district of Nampula.] *An. Inst. Med. trop., Lisbon*, 1953, 10, 1331-1344. *Proc.* English summary.

An investigation was made of 729 natives between the ages of 20 and 50 years in the District of Nampula, Mozambique, to assess their state of nutrition, physical development and robustness. Measurements were made of height, weight, chest circumference and expansion, vital capacity, Hb and Pignet's index, as well as observations on the presence of adipose tissue and signs of riboflavin deficiency. The results showed that the subjects were short in stature, of good somatic constitution, but of low weight, in spite of having their ribs well covered with adipose tissue. Twenty-one per cent. were anaemic and 84.7 per cent. showed signs of riboflavin deficiency, in the form of glossitis and

cheilitis. It was concluded that diets had insufficient amounts of fats and of foods containing vitamin B₂, and that the adipose tissue came from the carbohydrates.

An outline is given of the foods available; these contain all the components necessary for a good diet, but in their ignorance of dietary requirements the people are content merely to satisfy their hunger. This ignorance must be removed by propaganda, but at the same time they must be enabled to obtain a suitable diet at low cost. The means suggested are more intensive culture of groundnuts and cottonseed for oil, and the introduction of the soya bean. Ten per cent. soya meal could be added to flours. The official schedules of diets issued to employers of labourers are not perfect, and suggestions are made for their improvement. The employers should provide supplements of bananas and food yeast and should see that the workers have 3 well balanced meals in the day. In this way they will improve the health of their employees and increase their output; in the end they will have cheaper labour.

M. B. Richards.

2581

ARAÚJO DE FREITAS, J. Trabalhadores indígenas de Angola, sua alimentação, doenças predominantes e algumas medidas profiláticas adoptadas. [*Indigenous workers in Angola, their diet, common diseases and some of the preventive measures used.*] *An. Inst. Med. trop., Lisbon*, 1953, 10, 1157-1184. *Proc. English summary.*

The recent development of agriculture and industry in Angola has led to a large increase in the number of native labourers, who are now estimated to number about 300,000. These labourers are for the most part natives with poor physical constitution and a low standard of living, and beneficial effects have already resulted from their employment by private companies, which provide regular food and medical attention. In the smaller companies with 50 to 150 employees, the employer can obtain sufficient of the foods indispensable for a varied and well-balanced ration and there is, as a rule, no deficiency. This applies in general to the coffee and palm-oil industries. In the larger companies with 1000 or more workers and far from the coast, particularly those in the sisal industry, the employer may be unable to obtain sufficient supplies of essential foods, and there is frequently shortage of fresh foods and animal products. In these larger concerns there is evidence of protein and vitamin deficiency, in some cases clinically well defined. There is urgent need for study of the diets of the native labourers in different districts of Angola, and for classification of the nutritional diseases among them.

Predominant diseases are those endemic in Angola, such as malaria, acute affections of the respiratory tract, and diarrhoea and dysentery. Smallpox has almost disappeared as the result of vaccination campaigns, and sleeping sickness, already much reduced, will be eradicated within a few years. Of the imported diseases tuberculosis is regarded as the most serious, and immunisation, as practised by some companies, should be made compulsory.—M. B. Richards.

2582

SARMENTO, A. Alimentação dos Huambos. [*Diet of the Huambos.*] *An. Inst. Med. trop., Lisbon*, 1953, 10, 1113-1127. *Proc. English summary.*

The diet of the Huambos, one of the most important tribes of Angola, is predominantly vegetarian. It is based chiefly on maize and cassava flour, with sweet potato and leaves of cassava, bean or wild pumpkin. Fruits are appreciated, but are not abundant and their season is short. Meat obtained by hunting is scanty, but river fish are relatively plentiful from August to October. Meat and fish are usually dried and cooked as required; they are enjoyed, especially by the old, when slightly putrefied. For seasoning the people use salt, when they have the means to buy it, but sometimes they use the roasted and ground seeds of water melon, or sesame. Infants are normally breast fed, but not according to any time schedule, and they may continue to suckle up to 3 years of age, although they are given maize gruel from the age of a month. From birth onwards they are regularly given chissangua, a fermented drink prepared from maize flour and wild roots, and in spite of intensive propaganda against it, the custom continues. There is no special diet for the sick, but generally they are given a gruel of fine maize or cassava flour, and chissangua. A description is given of the meals and the different methods of preparation, the cooking utensils, the preservation of foods, mostly by sun-drying, and the primitive method of storage. Tobacco is grown, and is smoked habitually by both men and women.—M. B. Richards.

2583

DOS SANTOS BRÍGIDO, A. and GONCALVES, F. T. Apontamentos sobre o estado de nutrição de um grupo de crinaças macaenses. [*State of nutrition of a group of Macao children.*] *An. Inst. Med. trop., Lisbon*, 1953, 10, 1325-1329. *Proc. English summary.*

The diet of the people of Macao consists chiefly of decorticated rice with small quantities of salted fish and vegetables; it is almost devoid of meat and fruits. There is deficiency of proteins and vitamins. A study of the nutritional state of 95

Macao children between the ages of 6 and 17 years gave clinical evidence of nutritional deficiency in most. Eighty-five and 87 per cent. showed morbid changes in the buccal mucosa and tongue, respectively. Forty-two per cent. had bleeding gums, 11 per cent. oedema of the limbs, and 15 per cent. dental caries. The Hb values were almost always below normal. Heights and weights were inferior to those of children in other countries and there was retardation of sexual development in 10.5 per cent. of the children examined.

INDIAN STATISTICAL INSTITUTE. The national sample survey. 3. Tables with notes on the third round August-November 1951. *Sankhyā, Indian J. Statistics*, 1954, 14, 86-168.

The third round of the Survey differed from the first and second rounds (see Abst. 5111, Vol. 24) by extending to urban areas. The Survey included in all 13,500 households and the present report concerns consumer expenditure data collected from 6770 of them, 5080 scattered over 905 villages, 1180 in 49 towns and 510 in the 4 cities Calcutta, Bombay, Delhi and Madras. Of the 55 complete tables which are published 2 show the distribution of the sample blocks in towns according to size and the geographical distribution of the sample villages over the 6 population zones. Of the remaining 53 tables 37 refer either in whole or in part to foods consumed by the population. They show the total amounts and consumption value of these and the quantities and their value obtained by purchase or in exchange for goods and services. Similar data are given for individual foods per household and per head for the villages grouped according to population zones and for the urban areas.

Seven small tables summarise the findings and show some comparisons with the earlier rounds. In villages, towns and cities, respectively, total expenditure per person per month was 15.88, 17.27 and 25.29 R., 66, 55 and 46 per cent. of total expenditure. In the rural areas mean consumption value per household per week for all items was 28.62 R., of which 19.08 R. referred to food items, 10.65 R. being the value of the amounts of these received in kind. For urban areas corresponding values were 37.12, 19.92 and 3.36 R. per week.

Facsimile reproductions show examples of the types of field schedule used in this very extensive investigation.—D. Harvey.

PACHECO DE FIGUEIREDO, J. M. Contribuição para o estudo do problema de alimentação na Vol. 25, No. 2

India Portuguesa e a sua influencia sobre a saúde. [Problem of diet in Portuguese India and its effect on health.] *An. Inst. Med. Trop., Lisbon*, 1953, 10, 1233-1317. *Proc. [Esc. Med., Goa.] English summary.*

In a study of the nutrition of the population of Goa, 4 types of diets of schoolchildren aged from 9 to 10 years, and 14 diets of the working classes were studied. Of the children's diets all were insufficient in protein, and in quantity. In the diets of the adults the amount of protein was usually within normal limits, but as the protein was almost all of vegetable origin, the utilisation was poor. As in the children's diets, fat was deficient in both quantity and quality. One of the gravest defects of all the diets was their lack of Ca and the imbalance of the Ca:P ratio. All diets were deficient in Fe. In the children's diets vitamins A, B₁ and C were only one-third to one-half of the requirement, and there was scarcely any vitamin B₂. In the adults' diets vitamins A, B₂ and C were present in insignificant amounts, and only vitamin B₁ approached the indispensable minimum. The fundamental errors of the Goanese diets are the deficiencies of Ca, Fe and vitamins.

A survey is given of the incidence of deficiency diseases. In Goa infant mortality in 1951 reached 12 per cent. Examination of 673 schoolchildren showed that more than half suffered from hyperkeratosis, phrynodema, angular stomatitis or tongue fissures. A condition that must be considered is the incidence of intestinal parasites, which affect two-thirds of the population of Goa.

M. B. Richards.

2586

SHIGETOMO, A. [On the investigation of food in the endemic area of Kaschin-Beck's diseases.] *Shikoku Acta Med.*, 1954, 5, No. 3, 1-6. [Dept. Int. Med., Manchuria Med. Coll.] In Japanese: English summary.

Diet surveys lasting 5 days were made in 15 households in an area of Manchuria where Kaschin-Beck's disease, a disorder characterised by shortening of the long bones, is endemic. Five Chinese families in which it occurred and 5 Chinese, 3 Korean and 2 Japanese families from which it was absent were studied. Data for the intakes of energy and 9 nutrients are tabulated. No difference was found between the diets of the 2 groups of Chinese: their consumption of vegetables and of animal foods was low and their energy intake was probably also low. Intake of vitamin A, almost entirely as carotene, was ample in the Korean but in Chinese and Japanese families it was low. In all families the Ca intake was small, between 186 and 765 mg. per head, and that of Fe large, from 74 to 263 mg. per head daily. (From summary).—D. Harvey.

2587

- OWENS, L. and WHITE, G. S. Observations on food acceptance during mental illness. *J. Amer. Dietetic Assoc.*, 1954, **30**, 1110-1114. [Dept. Mental Hyg., State of California, Sacramento.]

Average plate waste per head per day in 3 dining rooms serving 200 chronically ill male schizophrenic patients was recorded for 18 months during which special efforts were made to make food more palatable and attractively served. The dining room with cafeteria service showed consistently less waste than the 2 with family type service. Change from family type to cafeteria service in one dining room reduced plate waste. The lowest average plate waste of 6 oz. per head per day was obtained when cafeteria service with a selective menu was available. The highest average waste was 24 oz. in a dining room with family type service. This was reduced by improvement in food palatability.—F. C. Aitken.

ACOSTA-SISON, H. and VILLANUEVA, J. **Nutrition of women during pregnancy with Philippine food material.** *J. Philippine Med. Assoc.*, 1954, 30, 151-169. [Dept. Obstet., Univ. Philippines.]

Diets composed entirely of foods produced in the Philippines, with the exception of butter, canned milk and flour, were given in hospital to 47 poor Filipino women for from 1 to 5½ months of their pregnancy. Menus are given to illustrate the diets provided and to show their nutritional adequacy. Two tables give details of weight gains during pregnancy, birthweights of the infants, and results of blood and urine analyses. The optimum weight gain was found to be from 3 to 4 lb. a month, and mothers with such increase

produced infants of average birthweight 3500 g. Mothers with higher or lower weight gains produced infants smaller than average. Most women had low red cell counts and low Hb values on admission, and the blood picture improved on the controlled diet. The study demonstrated the possibility of achieving satisfactory nutrition for pregnant women on diets suited to their tastes and means.

VIGLIANI, E. C. **Problemi di alimentazione per i lavoratori esposti all'azione di sostanze tossiche. [Feeding of workers exposed to the action of toxic substances.]** *Med. del. Lavoro*, 1954, 45, 423-430. [Clin. Lavoro L. Devoto, Univ. Milan.] English summary.

All workers exposed to toxic substances should be well fed, but the use of any special diet should not be allowed to give rise to a false sense of security. No diet is considered to have a specific value against any particular poison. Milk has no specific action against lead. Workers with benzene or aromatic amines should have foods containing proteins rich in sulphur amino-acids. In work with chloroform, carbon tetrachloride or tetrachloroethane, high reserves of glycogen in the liver should be maintained; that is, the diet should be rich in carbohydrate and liver-protecting amino-acids. The diet for workers with trinitrotoluene should be like the last and also poor in fat. Alcohol is considered undesirable for workers with toxic substances, particularly calcium cyanide and nitroglycerine, but methanol poisoning may be partly counteracted by ethanol and pectin. Workers should not expose themselves to CO immediately after a meal. Workers with penicillin should be given B vitamins to combat liability to blacktongue.

FOOD ECONOMICS AND STATISTICS

2606

STRAUB, J. and SCHOUTRA, A. De waarde van calorieën en eiwit, in geld uitgedrukt, de "voedselgeldswaarde". [The value of calories and protein, expressed in money; the "diet money value".] *Voeding*, 1954, 15, 210-218. [Centraal Inst. Voedingsonderzoek T.N.O., Utrecht.] English summary.

Money value is computed from the chemical composition of the food on the assumption that 50 Cal., 1 g. animal protein and 2 g. plant protein are worth 1 cent. The values are set out for 55 common foods and the relation of money value to cost is shown in a diagram.—I. Leitch.

2607

JAPPÉ, W. G. Intento de comparacion de los valores economicos y nutricionales de algunas cosechas. [Relative money and nutritional values of some food crops.] *Arch. venezol. Nutricion*, 1954, 5, 89-93. [Inst. Nac. Nutricion.] English and German summaries.

The economist evaluates a food product by its price and the agronomist by its weight, but there is no such simple basis for the nutritionist to work on. The food value of several crops has been compared in the following way. The net yield per hectare is calculated by subtracting from the gross yield the normal losses during refinement, transport and selection of the edible portion. The energy value and contents of protein, Ca, P, Fe and several vitamins are estimated and each is divided by the value of the daily requirement of an adult man. For example, a hectare of rice with a net yield of 945 kg. and a protein content of 8 per cent. gives a total of 75.6 kg. protein; if the daily protein requirement of an adult man is 70 g., the crop of rice provides 1080 daily protein rations. This method is applied for each food constituent to rice, black beans, maize, potatoes, pawpaw, plantains, yuca and tomatoes. It demonstrates well the imbalance of nutrients in each crop, which must be considered in the evaluation, as must differences between the biological value or utilisation of components from different sources.—D. Duncan.

2608

WILCOX, W. W. Methods of increasing domestic consumption of farm products. *J. Farm Econ.*, 1954, 36, 509-512. [Library of Congress, U.S.]

This paper confines itself to ordinary commercial methods of dealing with the present excess agricultural production in the U.S. by increased domestic consumption, with special reference to livestock products; among the measures suggested are expansion of the school lunch programme and industrial canteen facilities, improved packaging and marketing and increased publicity for the nutritive value and uses of livestock products. Their importance in U.S. agricultural economy is shown by the facts that in 1952 livestock and livestock products provided 42 per cent. of farm income in cash, compared with 8 per cent. each for food grains and cotton; and of farm land in 1950, 72 per cent. was used to support livestock, quite apart from some 400 million acres of range land, compared with 6 per cent. for food grains and 2 per cent. for cotton. Nevertheless, since consumption per head has shown percentage increases since 1940 as follows: beef 41, veal 29, chicken 64, turkey 41, eggs 28, milk 6, cheese 19, ice-cream 52, with decreases only in lamb 28, pork 12 and butter 49 per cent., it is considered that a shift from cotton and food grains to the production of soil-building forage crops and the use of some food grains for livestock feeding are desirable.

NORDIN, J. A., JUDGE, G. G. and WAHBY, O. Application of econometric procedures to the demands for agricultural products. *Iowa Agric. Exp. Stat. Res. Bull.* No. 410, July 1954, 979-1035. [Dept. Econ.]

The first half of this study consists of a mathematical discussion of the problem of predicting retail demand by the method of least squares or by simultaneous equations methods.

In the second half, the theory is applied to U.S. demand for (1) pork, beef and poultry meat, (2) eggs. For the meats, a simultaneous equations method was considered more satisfactory and yielded the following tentative predictions: a 1

N.A. and R., April 1955

per cent. rise in the price of pork will bring a 0.91 per cent. fall in the quantity of pork retailed, and a 1 per cent. rise in disposable personal income will bring a 0.76 per cent. rise in the quantity of pork retailed. The corresponding figures for beef were 0.77, 0.65 per cent., and for poultry meat 0.68, 0.53 per cent. The effects of changes in relative prices are also discussed and it is considered that such changes are less likely to affect consumption of poultry meat than that of either pork or beef. For eggs, the least squares method seemed preferable, and the corresponding figures were 0.55, 0.41 per cent.—W. M. Deans.

2610

PHILLIPS, T. L. **Income levels and meat consumption in Australia.** *Quart. Rev. Agric. Econ.*, 1954, 7, 123-128.

In Australia, falling wool prices lead to an increased supply of mutton and also, through a decline in general income level, to an increased demand for it. This is brought out by a table of returns from wool and mutton, sheep numbers and mutton production for the years 1927 to 1952, war years omitted. Another table gives consumption per head and wholesale price per lb. of mutton, lamb and beef, along with national income per head (that of 1928-29 taken as 100) for the same period; the data are also shown graphically. The average long-term meat consumption pattern is, approximately, beef and veal 60, mutton and lamb 32 and other meat 8 per cent. In 1928-29 the quantities consumed per head in lb. were beef 115, mutton 56, lamb 12 but by 1932-33 (national income per head 66) they were 93, 74, 14. In 1938-39 (national income per head 93) they were 132, 62, 14 and in 1952-53 (national income per head 344), 118, 48, 29. So far as changes in price are concerned, beef shows a time lag compared with mutton.—W. M. Deans.

VIITA, P. **Maatalous Suomen kansantulolaskelmissa. [Agriculture in the computation of the national income in Finland.]** *Maataloust. Aikakausk.*, 1954, 26, 121-129. [Central Statistical Office, Helsinki.] English summary.

A table is given showing the position of agriculture in the Finnish national economy between 1926 and 1952. Until 1939 agricultural production followed general economic development, but since then it has been at a relatively lower level than in other industries. [From summary.]

D. Harvey.

2612

Fox, F. W. **Agricultural foundations of nutrition.**

8. Dairy produce, with special reference to fresh milk. 9. Sea-foods. 10. Vegetables. *S. African Med. J.*, 1954, 28, 770-773; 897-

Vol. 25, No. 2

899; 1019-1022. [S. African Inst. Med. Res., Johannesburg.]

For Parts 6 and 7 see Abst. 1127, Vol. 25.

8. In South Africa the demand for liquid milk is low: in 1951-52 consumption, as percentage of the total produced for sale, was as fresh milk 41, butter 45, cheese 8 and condensed or dried milk 6. The milk cow population is between 0.8 and 0.9 million. Information on yield is scanty; there is evidence which suggests that it is about 1.1 gal. per cow daily. Data collected in 1937 showed that, for Europeans, with rising income consumption of milk and butter rose, that of meat and cheese was affected little and that of condensed milk fell. To produce an increase of consumption only a reduction of price is likely to be effective.

Problems in connection with feeding which are discussed are those of increasing pasture and reducing dependence on concentrates; others related to the siting of farms near towns where land and labour are expensive, to the acceleration of transport and the cutting of its cost and to the reduction of losses from disease in herds are also mentioned. Experience in Port Elizabeth in the use of sterilised milk suggests this may be an important development.

9. The rapid growth of the fishing industry in South Africa is traced in tables showing total catches and data from the related canning, fish-meal and marine oil industries. Hake liver oil is a cheap source of vitamin A and in the experience of some gold-mining companies there is evidence that the African's prejudice against fish may be overcome. The results of small-scale investigations on the use of fishmeal in diet scales for Africans have also been encouraging.

10. Between 1937 and 1950 the total area planted in all kinds of vegetables, including potatoes, nearly doubled; the percentage increase was least for sweet potatoes, 26 and greatest for onions, 179. Regarding scales of 8 vegetables in the 8 principal municipal markets information was that increases over 12 years ranged from 45 per cent. for green beans to 195 per cent. for cauliflowers. In a consideration of problems of transport the long distances that some vegetables are carried require consideration, e.g., 90 per cent. of its tomato supplies had travelled 1300 miles to Cape Town and green peas had gone between 200 and 500 miles to the markets of 4 important cities.

More detailed reference is made to the growing of potatoes; a substantial reduction in their price is thought to be possible only if production is rendered less precarious and if fluctuations in the returns to growers are reduced.—D. Harvey.

2613

SZCZYGIŁŁ, A. and SZCZKÓWNA, J. **Postulaty żywieniowców w zakresie norm spożywcia**

warzyw i owoców. [Some nutritional claims with regard to the production and consumption of fruits and vegetables.] *Rocz. Państwowego Zakł. Hig.*, 1954, 5, 221-226. [Dział. Hig. Żywności PZH.] Russian and English summaries.

In a review the national consumption of fruits and vegetables is given and compared with the norms suggested by the Polish Department of Food and Hygiene in 1950, and with the current or planned consumption of these products in other countries. The variety of fruits and vegetables should be increased and supplies to the market made regular.

In addition, the desirable annual consumption per head of individual fruits and vegetables during the next 5 years is outlined. (From summary.)

REED, R. H. and CREEK, C. R. **Family consumption of certain fresh vegetables in Honolulu.** *Hawaii Agric. Exp. Stat., Agric. Econ. Bull.* No 5, June 1953, pp. 22.

During the month of October 1951 810 households chosen at random in the city of Honolulu were visited. The vegetables eaten were cabbage, tomatoes, lettuce, carrots, cucumbers and sweet potatoes and the average amounts used per head in that order were 1.37, 1.34, 0.83, 0.80, 0.42 and 0.27 lb. The consumption of all vegetables except cabbage increased as family size increased; for cabbage, the cheapest vegetable, consumption decreased as family income increased. Racial differences in rates of consumption were statistically significant only for tomatoes, cabbage and lettuce. In general there was a preference for medium size in the vegetables and for firmness in cabbages and lettuces. For carrots, imported supplies were preferred to those grown on the island, but for the other types the opposite was true. Good quality and attractiveness of display often prompted purchases which had not earlier been in mind.—G. F. Garton.

BENGOA, J. M., GONZÁLEZ, M. and CARILLO, A. S. **Hojas de balance de alimentos en Venezuela en 1951.** [Food balance sheet for Venezuela in 1951.] *Arch. venezol. Nutricion*, 1954, 5,

95-111. [Inst. Nac. Nutrición.] English and German summaries.

The Instituto Nacional de Nutrición has prepared a balance sheet for production, expenditure and consumption of food in 1951. This takes into account total production and changes in reserves, imports and exports, animal feedingstuffs, cereals, manufactures, waste, gross and net quantities of foods available, and estimated mean consumption per head of population by the year and day.

The population numbered about 5,050,000. The estimated daily diet provided 2372 Cal. per head, 64.1 g. protein, 44.7 g. fat, and by difference, 428.3 g. carbohydrate. Cereals accounted for 36.85 per cent. of the total calories and foods of animal origin for 13.54 per cent. [but the diagram on p. 103 shows 21.13 per cent.]. Of the total protein consumed 41.03 per cent. was of animal origin.

Energy intake was 90 Cal. per day higher than in 1950, but protein consumption was the same.

D. Duncan.

2616

BENGOA, J. M. (with FERNÁNDEZ, J. and ROJAS, V.) **Variaciones de los costos de alimentación en Caracas en los últimos veinte años.** [Change in the cost of food in Caracas in the last twenty years.] *Arch. venezol. Nutricion*, 1954, 5, 113-131. [Inst. Nac. Nutrición.] English and German summaries.

The costs in 1933 and 1952 were compared for 5 diets, poor, minimum, intermediate, optimum and luxury. The poor diet provided daily 1832 Cal. and 57 g. protein, 9 g. of animal origin, and represents the food of an important proportion of the population of Caracas. The luxury diet provided 3256 Cal. and 151 g. protein with a high proportion of animal protein; the other diets lay between these extremes.

The cost per person and day was for the poorest diet 0.45 bolivar (B) in 1933, 0.86 B in 1952; for the intermediate diet 1.23 and 2.22, and for the luxury diet 3.26 and 5.65. The increase was from 67 to 91 per cent. for different diets. Of the poor diet, 1.00 B would buy 4166 Cal. in 1933 and 2130 Cal. in 1952; the same sum would buy 126 g. protein in 1933 and 66 g. in 1952.

The increase in costs of different nutrients and of the different types of diet has been uniform.

DIET IN ETIOLOGY OF DISEASE

METHODS OF ASSESSING STATE OF HEALTH

2617

CORRENTI, V. **Lo spessore del pannicolo adiposo sottocutaneo in eutrofici e distrofici dei primi 30 mesi di vita. 2. Risultati delle misurazioni del pannicolo adiposo sottocutaneo in bam-**

bini eutrofici del primo anno di vita (1). [Significance of the subcutaneous fat layer in well-nourished and dystrophic infants during the first 30 months of life. 2. Results of measurement of subcutaneous fat in eutrophic infants during the first year of life. 1.] *Quadr.*

N.A. and R., April 1955

Nutrizione, 1953, 13, 61-76. [Clin. Paediat., Univ. Rome.]

For part 1 see Abst. 2566, Vol. 21.

The infants, 18 boys and 8 girls, were healthy and were from 3 to 14 months old. The subcutaneous fat was measured in 8 sites on the body and the measurements were repeated 31 days later. The results are presented statistically. The mean thickness of fat was greatest in the gluteal region and then, in descending order, on femoral, umbilical, lumbo-abdominal, scapular, mammary and anterior brachial sites and the back of the hand. An index, I.M.I.A.S., derived from values for all 8 sites, was positively correlated with bodyweight, and it is considered that it might be a useful guide to the state of nutrition.—D. Duncan.

ACHESON, R. M. **Method of assessing skeletal maturity from radiographs. A report from the Oxford Child Health Survey.** *J. Anat.*, 1954, 88, 498-508. [Social Med. Unit, Univ. Oxford.]

The disadvantages inherent in the inspection technique which is commonly used for the rapid assessment of maturation are indicated. To overcome them a system is suggested which is based on the awarding of scores according to the stage of development of bones. On the assumptions that (1) the hand and knee should be treated separately, (2) scores for round bone and epiphyseal ossifications may legitimately be added together, and (3) suitable corrections should be applied so that in the end the graph for skeletal maturity in units against age in years shall be linear, the system has been applied to measure the development of hands and knees in a group of 97 healthy British children between 6 months and 5 years of age (see Title 812, Vol. 23 and Ryle, "Changing Disciplines", Oxford Univ. Press, 1948). Mean scores for age and sex at half-yearly intervals are given. The possibility is visualised of applying the system to any part of the body and of expressing skeletal maturity as a percentage of normal.—D. Harvey.

BABCOCK, M. J., CLAYTON, M. M., FOSTER, W. D., LOJIKIN, M. E., TUCKER, R. E., VANLANDINGHAM, A. H. and YOUNG, C. M. **Cooperative nutritional status studies in the northeast region. 6. Correlations.** *W. Virginia Agric. Exp. Stat. Bull.* No. 361T, June 1953, pp. 48. [Morgantown, W. Va.]

For earlier references to this series see Abst. 2265, Vol. 24.

Data from six districts for 1559 subjects were examined for the existence of associations between 4 blood constituents, 7 dietary nutrients and 22 physical signs. The statistical methods employed are outlined.

Vol. 25, No. 2

Simple correlation coefficients between blood constituents and related dietary nutrients showed that at nearly all stations the associations were significant for Hb with dietary protein, Hb with dietary Fe, blood vitamin A with blood carotene and blood ascorbic acid with dietary ascorbic acid. There was, in addition, a tendency for some other associations to be significant, but this may have been due to the occurrence in high concentrations of more than one nutrient in a single type of food e.g. carotene and vitamin C together in green leafy vegetables.

Physical signs were recorded only in descriptive terms and further statistical procedures were used to measure the association of these with either blood constituents or dietary nutrients or both, but in no case could the presence of a physical sign be accurately predicted from any combination of blood constituents and dietary levels that was tested.

It is suggested that findings in studies based on cross-sections of a population should be confirmed by longitudinal studies of the same population.

D. Harvey.

MAYER, A. J. and MARKS, R. V. **Differentials in infant mortality by race, economic level and cause of death, for Detroit: 1940 and 1950.** *Human Biol.*, 1954, 26, 143-155. [Wayne Univ., Detroit.]

2621

BAIRD, D., WALKER, J. and THOMSON, A. M. **The causes and prevention of stillbirths and first week deaths. 3. A classification of deaths by clinical cause: the effect of age, parity and length of gestation on death rates by cause.** *J. Obstet. Gynaecol. Brit. Empire*, 1954, 61, 433-448. [Dept. Midwifery, Univ. Aberdeen.]

For Parts 1 and 2 see Absts. 2767, Vol. 22 and 3439, Vol. 23.

A detailed description is given of the method of classification applied to 1008 obstetric deaths (stillbirths and first week deaths). About one-third of the deaths were unexplained and of these about 60 per cent. were associated with prematurity of unknown cause. In the remaining cases death was due to injury at birth, pregnancy toxæmia, antepartum haemorrhage, foetal deformity, maternal disease and other causes. From a study of the effect of age and parity on the different causes of death it is suggested that the ageing process, especially in primiparae, is associated with a decline of reproductive efficiency. The natural rise with age in obstetric death rate is masked by

the use of caesarean section, especially in primiparae over 25 years, and by the tendency for the advantages of youth to be outweighed by the ill effects of poor growth and poor general health in primiparae under 20 and multiparae under 25 years. The underlying cause of death in the mature, cause unknown, group, in prolonged pregnancies appears to be a failing oxygen supply, and this cause, combined with a rising incidence of difficult labour, brings about an increase in traumatic deaths after term.

A higher level of health among mothers and reproduction at more favourable ages would be required in addition to good obstetric care to achieve the lowest possible obstetric death rate.

F. C. Aitken.

2622

GRIFFITHS, J. **Child health in Johannesburg.** *Med. Officer.* 1954, 92, 199-204. [City Health Dept.]

This article includes tables and graphs giving the birthrate and infant mortality rate for European, native, Coloured and Asiatic sections of the population of Johannesburg, and birthweight, parity, breast feeding percentage and incidence of infections for European, Coloured and Asiatic infants attending child welfare clinics, all for the year July 1950 to June 1951.

Infant mortality per 1000 live births was: Europeans 27.44, Asiatics 48.54, Coloured 80.51, natives 243.76, but there is reason to believe that the last figure is artificially high. The lower the mortality, the higher the percentage of deaths very early in life. Prematurity was the commonest cause of death among Europeans and Asiatics, diarrhoea among Coloured and native; respiratory disorders were also a frequent cause among natives. The last two, it is suggested, are associated with malnutrition.

Among clinic babies, Coloured and Asiatics tended to be lighter at birth than Europeans. Gross malnutrition was seen in 10 per cent. of Coloured, 11 per cent. of Asiatics and 0.7 per cent. of Europeans; half of the Asiatic and 11 per cent. of the Coloured malnourished infants had florid rickets. In the first 3 months complete breast feeding was considerably more frequent in the non-white races, but it fell away thereafter so that at 6 months the incidence was a little over 20 per cent. in all 3 races, probably because more of the non-white mothers had to go out to work. Infections tended to be commoner among Coloured and Asiatics but most of the differences were not statistically significant.—W. M. Deans.

2623

PLATT, B. S. **The malnourished community. Care of mothers and children as a first step towards**

improved feeding. *Lancet*, 1954, 267, 929-930; 931. [Dept. Human Nutr., Univ. London.]

The part that maternal and child welfare work among unsophisticated peoples may play in their social and economic development is considered with special emphasis on the needs for restraint in the introduction of innovations and for ensuring that, as far as possible, changes should be in agreement with the customs of the community.

HILBER, H. and MENTZ, B. **Schwangeren-Ernährung und Gesundheitszustand der Säuglinge. [Diet in pregnancy and the health of the infant.]** *Münch. med. Wochenschr.*, 1954, 96, 1027-1031. [Kinderkrankenhaus, Schwabing, Munich.]

The importance of adequate provision of protein, energy, Ca, P, Fe and vitamins for pregnant and lactating women is discussed with reference to the incidence of stillbirths and the health of surviving infants. A survey in Munich and Bavaria showed that there was frequently a deficiency of Ca, P and Fe in the diet of pregnant women and that only 40 per cent. had a satisfactory intake of protein. When improvements in nutrition could be effected both mother and infant showed the benefit. More modern methods of instruction in dietary principles are advocated for antenatal clinics.—A. M. Copping.

2625

VAVICH, M. G., KEMMERER, A. R. and HIRSCH, J. S. **The nutritional status of Papago Indian children.** *J. Nutrition*, 1954, 54, 121-132. [Dept. Nutr., Coll. Agric., Univ. Arizona, Tucson.]

Of the 115 children studied, 48 attended schools of the U.S. Indian Service and 67 attended private schools. Ages ranged from 11 to 16 years. Children in the Indian Service schools received a midday meal which supplied on the average daily 636 Cal., 22 g. protein, 172 mg. Ca, 48 mg. Fe, 3.8 mg. nicotinic acid, 0.42 mg. vitamin B₁, 0.53 mg. riboflavin, 57 mg. ascorbic acid and 2466 I.U. vitamin A. The noon lunch in the private schools was limited and not well planned, often of bread, water and potatoes. Such information as could be obtained about home diet suggested that it consisted mainly of beans, sugar and syrup, coffee, lard or fat pork, tortillas made of maize or wheat, small amounts of native foods such as mesquite beans, buds and fruit of cholla, fruits of prickly pear and saguaro cactus, with some wild greens in season. Very little animal protein was eaten.

Differences in height and weight between the 2 groups were not significant. Children attending Indian Service schools had significantly more

N.A. and R., April 1955

vitamin A potency and ascorbic acid in the blood, and hyperkeratosis and gingivitis were less frequent than in children attending private schools. There was no significant difference in serum riboflavin values between the groups. The incidence of asymptomatic stomatitis was slightly higher in the Indian Service schools. Only a few signs of nicotinic acid deficiency were noted. Average values for serum cholesterol were within the low normal range, for serum glucose and protein within the normal range, and not significantly different between the groups. Hb, red cell count, white cell count, haematocrit and sedimentation rate did not differ significantly between the groups. In both groups the Hb value was within the low normal range. Girls from the private schools showed poorer bone calcification than girls from the Indian Service schools.

The differences between the groups were attributed to the differences in quality of the school lunches.—F. C. Aitken.

DELGADO, J. A. DE B. A. **Incidência e condições de desenvolvimento das doenças edêmicas na área sanitária de Tete e causas das doenças da nutrição. [Incidence and conditions of development of endemic disease in the sanitary**

area of Tete and causes of nutritional disease.]

An. Inst. Med. trop., Lisbon, 1953, 10, 1779-1792. English summary.

Tropical diseases abound in the region of Tete in Mozambique. The numbers of cases are given for the 5 years from 1947 to 1951 of such diseases as malaria, amoebic dysentery, ankylostomiasis, tropical ulcer, leprosy, venereal disease and schistosomiasis. The causes of the nutritional diseases in Tete are directly related to the severity of the climate with its excessive heat and scarcity of rain, the poverty of the soil, and the indiscriminate use of alcohol. The diet of the people is based on carbohydrate-rich foods such as millet and maize flours, is insufficient, and deficient in vitamins B₁, C, D and in nicotinic acid.

M. B. Richards.

2629

JORGE JANZ, G., PINTO, G. L. and FRANÇA, C. S. **Contribuição para o estudo do estado de nutrição da população de S. Tomé. Sobre o estado de nutrição dos servigais em S. Tomé. [State of nutrition of the population of São Tomé. State of nutrition of rationed labourers of São Tomé.]** *An. Inst. Med. trop., Lisbon*, 1953, 10, 1459-1513. English summary.

A nutritional survey was made on 100 farm labourers in São Tomé, who were given a diet in accordance with regulations. The investigation included a detailed clinical examination, haematological tests, biochemical examinations of blood and urine, and a study of the prescribed dietary schedule. Consideration of all the clinical and laboratory data indicated that the group studied was in a state of malnutrition, as evidenced by the frequency of anaemia and of dental caries, and of the occurrence of signs of vitamin deficiency such as follicular hyperkeratosis, xerosis of the skin, tongue lesions and low excretion of riboflavin and vitamin B₁. Possible reasons for the lack of correlation between the observed state of malnutrition and the consumption of a ration which is largely in accordance with the usual requirements are discussed.—M. B. Richards.

BERVOETS, W. P. **Étude sur l'état de nutrition d'un groupe d'enfants indigènes. [Study of the nutritional state of a group of native children.]** *Ann. Soc. belg. Méd. trop.*, 1953, 33, 545-552. Flemish summary.

Assessment of nutritional status for Africans is made especially difficult by the complicated mixture of the races and the lack of standards. The serum proteins were estimated before and after administration for 3 months of milk powder to provide the equivalent of 750 ml. milk daily. Blood and urine tests and tests of liver function were used to eliminate children with actual disease.

Fifty-five boys, aged from 10 to 15 years, were investigated. The values for serum proteins of Wolfson *et al.* (*Amer. J. Clin. Pathol.*, 1948, 18, 723) were taken as normal. Before the distribution of milk, the percentage of children having subnormal values was for total protein 67.2, albumin 100.0, and globulin 20.0; for the last many had values above normal. After distribution of milk, the percentages with subnormal values was reduced to 3.6 for total protein, 78.1 for albumin, and 1.8 for globulin. Thus, the globulin values were less reduced and recovered more completely than those for albumin. The sedimentation rate also was improved.

DOS SANTOS REIS, C. M. Alimentação da mãe indígena e aleitamento. [*Diet of the indigenous [Mozambique] mother and lactation.*] *An. Inst. Med. trop., Lisbon*, 1953, 10, 1345-1437. *Proc.* English summary.

The problem of malnutrition among native infants in Mozambique is very serious. The infants are almost exclusively breast fed, and the high incidence of nutritional disorders and malnutrition suggested an investigation of the diet of the mothers in relation to the quantity and quality of their milk. It is shown that the native woman's diet, which might be sufficient in terms of energy for lactation under conditions of moderate physical activity, is insufficient in view of the hard work that she has to do. In addition it is ill balanced, with excess of carbohydrates and little fat and protein, and is deficient and ill balanced in vitamins and minerals. Milk is scant and of poor quality, and the average daily weight gain of infants is 24 g.—M. B. Richards.

LAURIE, W. Survey before service. Observations on relation between agriculture, parasite load, and nutrition on a tropical African island. *Lancet*, 1954, 267, 801-802. [*East African Med. Survey.*]

Because of alarming reports a medical survey was made of 3677 of the population of 17,000 people living on Ukara Island in Lake Victoria at a population density of 600 per sq. mile. Greying of the hair was seen in 11.2 per cent. of men and in 3.6 per cent. of women, but its nutritional significance is in doubt (see Osborne, *Abst.* 1156, Vol. 25). Cheilosis was found in 19.2 and 9.6 per cent. of men and women. The spleen was enlarged in 36 per cent. and the liver in 3 per cent. of the population. The incidences of hydrocele among men and of bancroftian infection in both sexes were high. Laboratory data showed that of 790 persons only 5 were free from intestinal parasites.

In spite of these infections the mean weight: height ratio for Wakara was 1.95, third highest among 31 tribes for which data are available.

A system of agriculture has been evolved under which full use is made of farmyard and green manures, adequate precautions are taken against soil erosion and a system of rotation of cropping is maintained. The density of population is 3 times that on the neighbouring mainland. The lesson is pointed of the value of surveying fully the population's ecological status before spending large sums of money on schemes for controlling disease.—D. Harvey.

SOEHARTO, R. Letter from Indonesia. *New Engl. J. Med.*, 1954, 251, 339-342. [*Djakarta.*]

A general practitioner in Djakarta gives a short description of the Indonesian Republic, its history, economy and facilities for medical education. The country still imports rice and its main nutritional problem is the provision of protein. The people, most of whom are Moslems, do not like milk or milk products; dried or salted fish are their main sources of protein. The death rate from liver cirrhosis among those over 18 years of age is thought to be 4.29 per cent. of total deaths.

D. Harvey.

MILLIS, J. A study of growth in the first year of life of Southern Indian infants born in Singapore. The influence of nutrition on the growth rate of Southern Indian infants born in Singapore. *J. Pediat.*, 1954, 45, 692-696; 697-706. [*Dept. Social Med., Univ. Malaya.*]

Means and 10th, 50th and 90th percentiles are tabulated for weight in oz. at 4-week intervals from birth to 12 months of 50 male and 56 female infants born in hospital in Singapore in the summer and autumn of 1951 to poor South Indian parents, mostly Tamils. Mean lengths in inches at birth 24, 36 and 48 weeks are also given. Mean weights of male infants are plotted along with results of the author for poor Chinese in Singapore (*Med. J. Austral.*, 1954, 1, 283), of Vickers and Stuart for Americans of northern European stock in Boston (*Abst.* 467, Vol. 13) and of Clements for Australians (*Abst.* 2179, Vol. 3). At birth the sexes were alike with mean birthweight of 6.3 lb. and mean birth length of 18.8 in., but by the end of the year the males were significantly heavier and longer. Indian infants were lighter than Chinese infants throughout, and in the second 6 months both Asian groups fell behind the white groups. Further study would be required to ascertain whether the differences are racial or environmental in origin, or both.

The second paper reports information on feeding and environment collected during the same

survey. At 12 weeks 41 per cent. of the Indian infants were wholly and 64 per cent. partly breast fed and 20 per cent. were still partly breast fed at one year; these figures are lower than those for Chinese infants in Singapore. The commonest reason for weaning was failure of lactation and it is suggested that this was partly due to the poor diet, low in protein, Ca and vitamins, of the Indian mothers and to food taboos and staying indoors during the first month after delivery. Artificial feeding was on dried or sweetened condensed milk; liquid cow's milk was too scarce and dear. Feeding on demand was usual until the child was given a mixed diet. Cereals, usually rice porridge, were not begun early, nor were fruit, vegetables or animal protein foods, and the amounts of the last were very small. Breast feeding favoured weight gains during the first 6 months but at the end of the year there was no significant difference. Infants breast fed for more than 24 weeks had a higher medical grading at 1 year and fewer infections than others. Differences in housing standards within the group had no demonstrable effect, but the generally low standard of living and hygiene was considered likely to have a detrimental effect on the health and progress of the whole group of infants.—W. M. Deans.

IGETA, M. [Study of physical changes in recruits from the time of enrollment to the initial training.] *Jap. Safety Forces Med. J.*, 1954, 1, No. 6, 13-18. [Camp Shibata.] In Japanese: English summary.

Recruits were examined on enlistment and at the end of their initial training. Physique was measured by the method of Pignet and Bornharardt, and was rated poor, satisfactory or fine.

On enlistment there were 70 recruits rating poor and 58 fine. Of the 70 poor, 46 improved to satisfactory or fine by the end of training. Of the 58 fine, only 5 deteriorated to satisfactory, and of those 3 had contracted diseases.

Humeral circumference measured at the end of training agreed with the rating of physique.

Hospital admissions were highest among poor ratings and lowest among fine. All recruits excused duties for sickness were in the poor rating group.

The food intake of all personnel was considered adequate in energy. [From summary.]

KONSTAM, P. G. Peptic ulceration in Southern Nigeria. *Lancet*, 1954, 267, 1039-1040. [Dept Surg., Univ. Coll., Ibadan, Nigeria.]

Twenty cases of proved peptic ulcer were seen in 9 months in Adeyo Hospital in Southern Nigeria, where cassava and yams are the staple

foods; in Northern Nigeria, where millets are common, the condition is relatively rare. It is thought unlikely that its occurrence is attributable to deficiency of any particular nutrient, but lack of vitamin B₁ may, at times, have an influence. The similarity is indicated between conditions in Southern Nigeria and those in Southern India as described by Orr and Rao (Abst. 3698, Vol. 9) and by Dogra (Absts. 3063 and 3694, Vol. 10).

2637

BLUMENTHAL, C. J. Blindness and malnutrition in the Eastern Cape Province. *S. African Med. J.*, 1954, 28, 967-971. [E. London.]

The incidence of malnutritional keratoconjunctivitis as defined by the author (see Abst. 887, Vol. 20) has been further studied. Among 1192 consecutive out-patients at Frere Hospital Eye Clinic the numbers of cases in the age groups 1 to 5, 5 to 15, 15 to 30, 30 to 50 and over 50 years were 57, 58, 29, 11 and 2. The condition is considered to differ from keratomalacia and to have its origin in damage caused to the mesodermal tissues of the eye by malnutrition after weaning and especially between 2 and 5 years of age. Such damage may not be visible to the naked eye. Flies, germs and dirt are discounted as its cause and are regarded only as incidentals.—D. Harvey.

2638

NICOL, D. Excess conjunctival tissue and follicular hyperkeratosis. *J. Trop. Med. Hyg.*, 1954, 57, 225-226. [Univ. Coll., Ibadan.]

In a pilot survey in Western Nigeria excess conjunctival tissue became more common with ageing and occurred more frequently among males than among females. The cause may be general irritation by dust and sunlight as suggested by Jelliffe *et al.* (Abst. 3562, Vol. 24); it is unlikely to be exposure to smoke, since women usually spend more time indoors than do men. In the same survey follicular hyperkeratosis was found to be more frequent in females than in males and in pregnant than in non-pregnant women. Oestrogens may in some way be involved in its appearance.

D. Harvey.

2639

MILLETTO, G. Le cancer du foie en milieu tropical. [Cancer of the liver in the tropics.] *Méd. trop.*, 1954, 14, 302-317. [Corps de Santé Colonial.]

Statistics are quoted to show the high frequency of primary cancer of the liver among native populations of tropical countries, from 22 to 51 per cent. of all cancers in India, Java and S. Africa, compared with its rarity in temperate countries, from 1 to 2.5 per cent. of all cancers in Europe and the United States, and also among white people living in the tropics. In America, the incidence of liver cancer is low in white and coloured people alike.

Among native Africans the disease affects men more often than women and is less frequent in urbanised communities than in those living a traditional African life.

No support was found for a theory connecting liver cancer with parasitic infestation. There is evidence that the malignant condition in the tropics is usually developed from a previous state of liver cirrhosis, a sequence which is rare in temperate countries. Research along these lines is considered to be most promising of useful results.

OKUSHI, I. Changes of the heart muscle due to chronic fluorosis. 1. Electrocardiogram and heart X-ray picture made in inhabitants of high-fluorine zone. *Shikoku Acta Med.*, 1954, 5, No. 3, 55-61. [Dept. Int. Med., Sch. Med., Univ. Tokushima.] Japanese summary.

Thirty-five persons, 25 children and 10 adults, were examined from a village where well water contained F, between 1.0 and 4.8 p.p.m., and 4 adults whose drinking water contained 6, 8.5, 8.5 and 13 p.p.m. Myocardial damage was detected electrocardiographically and cardiac dilatation by X-ray photography in a greater proportion of them than in other populations. It is suggested that the changes are due to the high intake of F and not, as considered by Okinaka (*Jap. Med. J.*, 1951, No. 1405, p. 3) to an endocrine disturbance.—D. Harvey.

2641

WALTERS, J. H. Uncommon endemic diseases of the Persian Gulf area. *Trans. Roy. Soc. Trop. Med. Hyg.*, 1954, 48, 385-394. [W. African Counc. Med. Res. Labs., Lagos, Nigeria.]

Nine persons showing skeletal fluorosis were seen, of whom 8 came from one area where water in the surface wells contained 8 p.p.m. F. In 4 of them who underwent full clinical examination neurological changes were found. It is suggested that the cause of these may have been toxic degeneration of sensory and pyramidal cells rather than compression of the spinal cord as was thought by Short *et al.* in similar studies (Abst. 5607, Vol. 7).—D. Harvey.

DE MAEYER, E. M. Traitement diététique du kwashiorkor. [Dietary treatment of kwashiorkor.] *Ann. Soc. belg. Méd. trop.*, 1954, 34, 139-154. [Inst. Recherche Sci. Afrique Centrale, Kivu, Lwiro, Belgian Congo.]

Full details are given of a dietary regime for hospital treatment of severe kwashiorkor. In the early stage, lasting 4 or 5 days, only milk reconstituted from dried skimmed milk was given. In the second stage, which followed when pancreatic enzyme activity was thought to have been sufficiently restored and which lasted for from 8 to 15 days, carbohydrate foods such as cooked rice, banana flour or fresh bananas were included. In

N.A. and R., April 1955

the final stage, lasting at least a month, the diet was generous, providing about 150 Cal. per kg. bodyweight, and included whole milk, palm oil, sugar, meat and fish, with Fe and vitamin supplements.—H. Chick.

WELBOURN, H. F. **Signs of malnutrition among Baganda children attending child welfare clinics.** *East African Med. J.*, 1954, **31**, 332-336. [Child Welfare Clins., Mengo District, Uganda.]

Among some hundreds of children, aged from 1 week to 3 years, attending a Kampala child welfare clinic definite signs of malnutrition were noticeable only in those older than 6 months, the onset coinciding generally with the time of weaning. In about one-half of the children the hair had in varying degree lost its tight curl and black colour. Soft golden-brown hair was seen in 10 cases of frank kwashiorkor. Oedema was always associated with other signs of the disease, but the characteristic skin changes were seen only in a few very severe cases. Dry or cracked skin was frequent and is attributed to deficiency of vitamin A. The apathetic and docile manner of most children is thought to be due often to kwashiorkor.

One case only of rickets was seen, in a boy 2 years old, who ate an unusual quantity of imported cereals including oatmeal, and whose mother went out daily to work and often left him indoors.

AGARWAL, L. P. and ADHAULIA, H. N. **Role of vitamin A in the healing of corneal ulcers.** *Ophthalmologica*, 1954, **128**, 6-14. [Dept. Ophthalmol., Med. Coll., Agra.] German and French summaries.

Superficial wounds were made on the cornea of 3 rabbits, and deep wounds on the cornea of 3 others. To 2 in each group an intramuscular injection of 10,000 I.U. vitamin A was given daily till the wound had healed. Vitamin A in the blood rose in those given the vitamin. In superficial and deep wounds, respectively, healing occurred in 2 and 2, and in 4 and 6 days for the 4 given vitamin

A, and in 4 and 8 days for the 2 not given vitamin A. The scar left by the deeper wounds was less dense when vitamin A was given.

Human subjects with corneal ulcers were given the hospital routine treatment and in addition 32 were given 300,000 I.U. vitamin A by intramuscular injection on the first and third day in hospital, and after that 100,000 I.U. daily till the ulcer healed. Thirty others received routine treatment only. The mean healing time in days for those given and not given vitamin A, respectively, was for non-sloughing ulcers 8.5 (11 subjects) and 10.7 (4), for sloughing ulcers 15.7 (15) and 25.0 (20), and for hypopyon ulcers 15.8 (6) and 20.1 (6). The density of the scar was less with vitamin A. Vitamin A was estimated in the blood and was considered to be somewhat low in the patients with sloughing and hypopyon ulcers.

2652

RUSHTON, W. A. H. and CAMPBELL, F. W. **Measurement of rhodopsin in the living human eye.** *Nature*, 1954, **174**, 1096-1097. [Dept. Physiol., Univ. Cambridge.]

A photocell system was developed with which the sensitivity of scotopic vision in man was measured by finding the rate of bleaching of rhodopsin in light of different colours. Use of the apparatus permitted direct estimation of the level of rhodopsin under different conditions. Preliminary studies seemed to show that unless bright photopic illumination was used there was no appreciable change in the density of retinal rhodopsin. Changes in visual sensitivity could not thus be due to an alteration in the chance of a quantum being absorbed but rather to a change in the efficacy of the quantum when it was absorbed.

JAMES, W. H. and HOLLINGER, M. E. **The utilization of carotene. 2. From sweet potatoes by young human adults.** *J. Nutrition*, 1954, **54**, 65-74. [Dept. Agric. Chem., Louisiana Agric. Exp. Stat., Louisiana State Univ., Baton Rouge.]

Carotene was estimated by a colorimetric method after purification by chemical and chromatographic procedures, the latter involving filtration through Ca(OH)₂ in the faeces of 8 healthy subjects, 5 men and 3 women, aged from 18 to 28 years. During the first month of the experiment the subjects were given diets low in carotene and vitamin A but adequate in other respects. In the second month they were given similar diets supplemented daily with 60 g. sweet potato, which provided 3500 µg. carotene. Both periods were divided into three sub-periods of 9 days each when the subjects were given daily (1) 150 g. fresh meat

and 12 g. milk solids; (2) 150 g. fresh lean meat and 120 g. milk solids, and (3) 300 g. fresh lean meat without milk solids.

During each of the sub-periods when the depleting diets alone were eaten the faecal carotene was on the average about 2 μ g. per g. faeces. In the period with the supplement the amount of carotene found in the faeces during the last 6 days of sub-periods 1, 2 and 3 was, respectively, 55.9 ± 3.6 , 57.6 ± 2.3 and 48.9 ± 3.2 per cent. of the 6-day intake of carotene. The average percentage for the total of 216 subject-days was 53.8 ± 1.6 . It is suggested that the comparatively wide difference between the percentages for sub-periods 2 and 3 may depend on the different influence of the proteins supplied by the milk solids and by the lean meat. Such an explanation is supported by experiments on rats in which the protein was supplied by lactalbumin, casein or zein (Abst. 1713, Vol. 24).—I. M. Sharman.

DITLESEN, E. M. L. and STØA, K. F. **Vitamin A and carotenoid levels in blood serum with special reference to values observed in diseases of the liver.** *Scand. J. Clin. Lab. Invest.*, 1954, 6, 210-216. [Biochem. Lab., University Hosp., Bergen.]

Vitamin A was estimated by the SbCl_3 reaction, and carotenoids by their yellow colour, in the blood serum of 228 normal and diseased human subjects. For 100 normal subjects the range in μ g. per 100 ml. was from 15 to 45 for vitamin A and from 50 to 200 for carotenoids. The averages for the 2 substances, respectively, were in men 29.6 and 91.5, and in women 25.9 and 102.5, and in both together 27.7 and 97. In 18 chronic alcoholics the average vitamin A value of 30.8 was about the same as for normal subjects, but the value of 57.8 for carotenoids was low. In 12 subjects with febrile diseases the average value for vitamin A was only 19.3 and for carotenoids only 59.4. In 13 patients with uraemia from several causes, mostly from chronic nephritis, the average value for carotenoids was about normal at 91.4, but that for vitamin A was very high at 65.9. In 6 patients with renal disease, but without uraemia, the averages were within the normal range, 98.3 and 27.5, respectively. In 14 patients with cirrhosis of the liver, the vitamin A value was always below 20, but that for carotenoids was normal. In contrast, the average for vitamin A was normal in 8 patients with obstructive jaundice, but that for carotenoids was low. In acute hepatitis both vitamin A and carotene were low. In 7 patients with cholecystitis and 7 with gallstones and no complication, the value for vitamin A was normal, but in cholecystitis that for carotenoids was low. The range for vitamin A in 16

patients with secondary carcinoma of the liver was wide, with limits of 5.1 and 42.3, but the average was low, only 17; the value for carotenoids also was low.—T. Moore.

2655

GRANDBOIS, J. La vitamine "A" en solution alcoolique dans le psoriasis. [Vitamin A in alcoholic solution for psoriasis.] *Laval méd.*, 1954, 19, 740-752. [Serv. Dermatol., Hôtel Dieu, Quebec.]

Synthetic vitamin A palmitate was dissolved in 95 per cent. ethanol in an atmosphere of CO_2 to give a solution containing about 800,000 "units" per oz. Ten patients with psoriasis of from 5 to 30 years' standing were treated for from 1½ to 15 months with a teaspoonful (about 100,000 "units") of the solution taken orally. Protocols are given for all 10. In 5 the lesions disappeared almost completely, in 4 there was important improvement, and only in 1 was there none at all. Some of the patients had previously taken vitamin A in other forms with less benefit. On cessation of treatment there was a tendency to relapse.—E. M. Hume.

Vitamin D

2657

JUNG, W. Zur Frage der angeborenen Rachitis. [The question of congenital rickets.] *Monatsschr. Kinderheilk.*, 1954, 102, 379-383. [Kinderklinik., Univ. Mainz.]

The old controversy on the existence or non-existence of congenital rickets is reviewed.

Between November 1952 and May 1953, and in October to December 1953, 420 newborn infants born in the University Frauenklinik were examined for rickets. X-ray photographs were taken of both wrists with special precautions to obtain a position where the focus would be exactly adjusted. In 368 the edges at the distal ends of the metaphyses of the radius and ulna were perfectly sharp. In 52 children the ends of the metaphyses of the radius and ulna were not well defined and showed different degrees of irregularity and softness of outline. Reasons are put forward for attributing such appearances to faulty placing, leading to lack of correct focus at the crucial point, and not to rickets. The relation of congenital craniotabes to rickets is discussed. Craniotabes was no less frequent among 65 infants born in a private nursing-home than among infants of lower social status. The phosphatase values for newborn infants with and without craniotabes

did not differ. The difficulty is stressed of distinguishing between the earliest signs of rickets and the effect of bad position of the limbs in the X-ray photograph. Diagnosis of early rickets should be made only from a series of photographs.

PARK, E. A. Bone growth in health and disease. The influence of severe illness on rickets. *Arch. Dis. Childhood*, 1954, **29**, 269-281; 369-380. [Dept. Paediat., Sch. Med., Johns Hopkins Univ., Baltimore, Md.]

In the first Leonard Parsons inaugural lecture the effect of severe illness on the normal growth pattern of bone was considered on the basis of examinations of bones from more than 1500 children who died after illnesses varying widely in duration. The conclusions were that bone should not be thought of as an inert tissue nor as one in which growth proceeds at a uniform pace; rather its formation affected by the general state of health of the child and, after periods of stress, there may appear in the X-ray photograph lines of arrested growth of cartilage, and the growth retardation lattice which originates in the inability of osteoblasts to deal with cartilage as fast as it is produced.

In the second lecture the effect of illness on the osteoblasts and cartilage cells in the rachitic state is first considered. The importance of inanition as the concomitant of illness is discussed, and un-

published experiments with rats are cited in which rickets produced by a diet low in P and high in Ca was cured by starvation but not prevented by partial starvation. In the child evidence is adduced that severe illness promotes rickets by depressing the concentration of Ca and P in the blood, but that by retarding growth it acts in the opposite direction. On the whole, it is considered that the tendency to promote rickets is the stronger.—E. M. Hume.

HARRISON, H. E. Mechanisms of action of vitamin D. *Pediatrics*, 1954, **14**, 285-295. [4940 Eastern Ave., Baltimore 24, Md.]

The research work of the author and his wife is reviewed. The lack of antirachitic activity in resistant rickets of vitamin D at low dosage and its efficacy at high dosage, together with the inactivity of dihydrotachysterol in rickets in low dosage and its equivalence of action with vitamin D at high dosage are discussed, and it is suggested that for vitamin D the biochemical mechanism at high dosage is different from that with which the vitamin ordinarily operates, the normal mechanism being blocked in refractory rickets. In healing of refractory rickets the serum P value does not return to normal. The part played by renal tubular re-absorption of P is discussed, and studies on the behaviour of serum citrate in relation to vitamin D are summarised. It is considered possible that the serum citrate concentration is related to the activity of those metabolic processes in the skeleton which actively destroy bone matter and dissolve bone salts. The abnormal urinary loss of amino-acids in rickets is regarded as further evidence that defect of specific renal tubular functions results from lack of vitamin D.

Acetazolesamide and maleic acid are both substances which interfere with tubular re-absorption. Maleic acid is isomeric with fumaric acid which forms one of the steps in the tricarboxylic acid cycle of Krebs. The effect of injecting Na maleate intraperitoneally (see following Abst.) is discussed. As interpretation of the failure of vitamin D to counteract the effect of maleate, it is suggested that vitamin D does not directly affect the mechanism of the renal tubules for re-absorption of P, or that maleate inhibits the functioning of some system without which vitamin D cannot exert its influence on tubular re-absorption.

E. M. Hume.

2663

HARRISON, H. E. and HARRISON, H. C. **Experimental production of renal glycosuria, phosphaturia, and aminoaciduria by injection of maleic acid.** *Science*, 1954, **120**, 606-608. [Dept. Paediat., Sch. Med., Johns Hopkins Univ., Baltimore, Md.]

Citrate, P, Ca and amino-acids were estimated in the urine of 18 rats, 6 weeks old, maintained for 3 weeks on a rachitogenic diet high in Ca and low in P, before and during 3 days on which a daily subperitoneal injection of 1 or 2 ml. 0.1 M Na maleate was given. Ca and citrate were greatly diminished, but P and amino-acids were greatly increased; glucose appeared in the urine. The effect soon began to diminish but could be elicited again after a pause in maleate administration. Control [nature of control not stated] rats showed no such effect.

It was thought most probable that the increased losses in the urine resulted from failure of tubular re-absorption, since there was no rise in the plasma values. Three rats were given 20,000 "units" of vitamin D 3 days before the beginning of the maleate injection but no change resulted in the response to maleate injection.

It is pointed out that the occurrence of renal glycosuria, phosphaturia and amino-aciduria is characteristic of the congenital metabolic defect in man which is called Fanconi syndrome and is resistant to vitamin D.—E. M. Hume.

BOHNCKE, H., LASSRICH, A., KRAUSFE, C. and MEYER, W. **Marmorknochenkrankheit mit "Rachitis" und Aminoacidurie.** [Marble bone disease with "rickets" and presence of amino-acids in the urine.] *Ztschr. Kinderheilk.*, 1954, **75**, 365-391. [Kinderkrankenhaus Hochallee, Hamburg.]

Three children, 2 from one family, with marble bone disease are described. All failed to thrive and died in infancy. The disease is essentially an osteosclerosis. Though changes like those of rickets may be present in the skeleton and there may be loss of amino-acids in the urine, it is considered improbable that deficiency of vitamin D has any part in the etiology.—E. M. Hume.

2665

ROBINSON, K. C., KALLBERG, M. H. and CROWLEY, M. F. **Idiopathic hypoparathyroidism presenting as dementia.** *Brit. Med. J.*, 1954, **ii**, 1203-1206. [Whittington Hosp., London, N.19.]

Idiopathic hypoparathyroidism is a rare condition. The patient under consideration was admitted to hospital at the age of 61 with a vague history going back for 7 years. She was disorientated

and apathetic, and subject to epileptiform seizures and attacks of tetany. The serum Ca value was 6.3 mg. per 100 ml. An X-ray picture of the skull showed calcification of the basal ganglia which frequently occurs in hypoparathyroidism. Successful treatment was by daily oral administration of 5 ml. dihydrotachysterol (A.T. 10) and 4 g. Ca lactate. Clinical improvement was rapid and a maintenance dose of 50,000 "units" calciferol was substituted after about a month. The rise of serum Ca was slow. The patient was discharged after a total of about 2 months, on the daily maintenance dose of calciferol and 4 g. Ca lactate.

ANDERSON, J., DENT, C. E., HARPER, C. and PHILIPOT, G. R. **Effect of cortisone on calcium metabolism in sarcoidosis with hypercalcaemia. Possibly antagonistic actions of cortisone and vitamin D.** *Lancet*, 1954, **267**, 720-724. [Med. Unit, University Coll. Hosp., London.]

Ca balance studies were made on 4 patients with Boeck's sarcoidosis in whom abnormally high values for plasma Ca had been recorded, which easily became still higher if vitamin D was given. Treatment with cortisone caused the plasma Ca to fall even when vitamin D was being given, and the patients felt much better, all having suffered from typical clinical manifestations of high blood Ca. The Ca balance studies showed that faecal Ca was abnormally low and urinary Ca high. Administration of cortisone increased Ca in the faeces, presumably by decreasing absorption.

WALTON, J. N. and NATTRASS, F. J. **On the classification, natural history and treatment of the myopathies.** *Brain*, 1954, **77**, 169-231. [Dept. Med., King's Coll., Univ. Durham.]

A series of 105 cases came under the personal examination of the authors; 84 had pure muscular

N.A. and R., April 1955

dystrophy affecting different parts of the body. The remaining 21 exhibited the myotonic syndrome. The clinical features and natural history of the cases are described and discussed, and the cases are classified into 3 broad groups, the Duchenne, the facioscapulohumeral and the limb-girdle type, with further sub-groups.

Groups of about 20 patients, each group providing a representative sample of the different types, were treated 3 times daily with tablets or capsules of 50 mg. synthetic α -tocopherol as Ephynal (Roche), or 3 mg. natural tocopherols as wheat germ oil (Crookes), or 50 mg. of a mixture of α -, β - and γ -tocopherols as Tocopherex (Squibb), or 100 mg. nicotinamide (B.D.H.) or dummy tablets. Treatment was continued for 6 months. Results are presented for 98 patients. None showed any objective improvement; subjective improvement was reported by a few in each group, 18 in all, including 3 of those given dummy tablets.—E. M. Hume.

LEWIS, L. A., QUATRE, M. L. and PAGE, I. H. Lipoproteins of serum, carriers of tocopherol. *Amer. J. Physiol.*, 1954, **178**, 221-222. [Res. Div., Cleveland Clin. Found., Ohio.]

The β -lipoproteins and low-density lipids of serum were concentrated with the ultracentrifuge at a density of 1.063 and the α + β -lipoproteins at a density of 1.21. In the whole serum of 12 normal human subjects α -tocopherol, and the β -lipoprotein and α + β -lipoprotein fractions were estimated. The average serum tocopherol value in mg. per 100 ml. was 1.47, of which 74 per cent. was carried in the α + β -lipoprotein fraction and 20 per cent. in the β -fraction. The mean serum tocopherol values of 4 patients who had been given 400 mg. tocopherol daily for 3 days rose to 2.18 from 1.04. After the short period of high intake only 60 per cent. of the tocopherol was concentrated in the lipoprotein fractions, compared with 80 per cent. before the treatment. The lipoproteins were divided into β_1 and low-density lipids, α_1 and α_2 fractions. When expressed as μ g. tocopherol per mg. lipoprotein the concentration in the α_2 -lipoprotein was about 10 times that in the β or α_1 fraction.—R. J. Ward.

2670

PROSPERI, P. and BORSELLI, L. Valori del tempo di ricalificazione e del tempo di protrombina dopo somministrazione frazionata ed unica di vitamina E. [Values for the clotting time of recalcified plasma and the prothrombin time after administration of vitamin E in several doses or in one.] *Riv. Clin. pediat.*, 1954, **53**, 73-81. [Clin. Pediat., Univ. Florence.] French and English summaries.

Vol. 25, No. 2

In order to ascertain the point of participation by vitamin E in the coagulation process, a study was made of the clotting time of recalcified plasma, or time of Howell, which is thought to measure thrombokinase activity. In 35 children aged from 2 to 16 years and in one of the authors, the prothrombin time (Quick) and time of Howell were estimated before the first, and in the first 4 groups of children 2 hr. after the last, dose of vitamin E. The vitamin was given orally to 10 children in 6 doses of 50 mg. at 2-hr. intervals, to 10 children in 3 doses of 100 mg. at 4-hr. intervals, to 5 children in 2 doses of 150 mg. with a 4-hr. interval, and by suppository to 5 children in 2 doses of 150 mg. with a 4-hr. interval. For the remaining 6 children a single dose of 300 mg. was given by mouth or by intravenous or intramuscular injection, and the tests were made 1, 2 and 3 hr. later.

It is stated that in all the children except 2, the time of Howell was reduced after administration of vitamin E in any of the different ways, but that for the prothrombin time there was no consistent result.

It is, therefore, concluded that vitamin E activates thrombokinase.—E. M. Hume.

2671

PROSPERI, P. and DELL'ORSO, S. La vitamina E nella profilassi delle emorragie dei neonati. [Vitamin E in prevention of haemorrhage in the newborn.] *Riv. Clin. pediat.*, 1953, **52**, 501-511. [Clin. Pediat., Univ. Florence.] French and English summaries.

Thirty-two women in the period up to 12 hr. before parturition were given a total of 500 mg. vitamin E, variously distributed, by intravenous and intramuscular injection or by mouth. Coagulation time, bleeding time and time of Howell were estimated before and after treatment, before parturition.

After treatment coagulation time was reduced in 19 women, unchanged in 11 and increased in 2; bleeding time was reduced in 16, unchanged in 13 and increased in 3; time of Howell was reduced in 23, unchanged in 8 and increased in 1. None of the infants showed any haemorrhagic sign and for the cord blood the time of Howell was almost always considerably less than in the mother.

E. M. Hume.

2672

NEUWEILER, W. and HÄMMERLI, U. Bemerkungen über die Vitamin-E-Resorption. [Absorption of vitamin E.] *Schweiz. med. Wochenschr.*, 1954, **84**, 884-885. [Frauenklin., Univ. Berne.] French and English summaries.

By mouth vitamin E was given as *dl*- α -tocopheryl acetate but, since the ester cannot be split

in the blood, it was given by intramuscular injection as *dl*- α -tocopherol. When the vitamin was given parenterally to non-pregnant women in a dose of from 600 to 1200 mg. the mean vitamin E content of the blood, in mg. per cent., rose from 356 to 1120, and when it was given by mouth, from 365 to 2113. In pregnant women the same greater effectiveness of oral administration was seen in the blood of the mother, and was reflected in the arterial and venous blood from the umbilical cord and in blood from the placenta. Oral administration has the further advantages that the ester is stable while the alcohol is less so, and irritation at the site of injection is avoided.—E. M. Hume.

2673

DE HOFF, J. B. and OZAZEWSKI, J. **Alpha tocopherol to treat diabetic retinopathy.** *Amer. J. Ophthalmol.*, 1954, **37**, 581-582. [Dept. Med. Ophthalmol., Med. Sch., Univ. Maryland.]

Twelve patients with long-standing, stabilised diabetes and retinopathy were given 3 times a day 200 mg. α -tocopheryl acetate for 2 months, and then 100 mg. After 15 months' treatment there was no increase in visual acuity and no change in the fundus lesions.—E. M. Hume.

Vitamin B Complex

2674

ONUMA, Y. [Survey of disposition towards beriberi among personnel of 11th Ship Division.] *Jap. Safety Forces Med. J.*, 1954, **1**, No. 8, 23-26. In Japanese : English summary.

Reports during part of 1954 of 4 men with beriberi prompted a survey; 10 men from each of 6 ships were examined and a questionnaire was circulated. [The total population is not stated.]

Five more actual cases and 50 men considered likely to develop the disease were discovered. Its appearance seemed to be more frequent among subjects who had had a debilitating disease such as pulmonary tuberculosis. The crowding and poor ventilation on ships is suggested as a contributory cause in addition to dietary deficiency. (From summary.)—D. Harvey.

2675

PALLISTER, R. A. **The electrocardiogram in oriental beriberi.** *Trans. Roy. Soc. Trop. Med. Hyg.*, 1954, **48**, 490-494. [Gen. Hosp., Penang, Malaya.]

A description is given of 25 cases of beriberi studied in Penang during the last 5 years. The cases had occurred sporadically and been relatively infrequent; they included one Malay, 15 Indian, and 9 Chinese patients. Diagnosis was made from the association of peripheral neuritis with heart failure, and from the rapid recovery on

treatment with vitamin B₁. Treatment included rest in bed, normal ward diet, injection of from 10 to 20 mg. vitamin B₁ daily, and a small amount of vitamin B complex, given by mouth.

In the acute cases the heart rate, with one exception, was over 100 per min.; slow rates were usual during recovery. In 16 of the patients the electrocardiogram was abnormal, and usually characterised by inversion of the T wave and prolongation of the QT interval. The electrocardiogram, which returned to normal in less than 6 weeks of treatment, was not considered to be specific but of help in diagnosis. The changes are similar to those described for cardiac beriberi in Europe or America, where it is commonly associated with alcoholism.—H. Chick.

2676

LANGERON, L. **Le bérubéri cardiaque d'origine alcoolique. Sa place dans l'insuffisance cardiaque d'origine alcoolique. A propos d'une observation. [Cardiac beriberi of alcoholic origin: its place in cardiac insufficiency of alcoholic origin. An observation.]** *Presse méd.*, 1954, **62**, 1385-1386. [Lille.]

In support of his belief that some cardiac insufficiency in alcoholics is caused by beriberi of alcoholic origin, the author presents a case of a young man of 26 with massive oedema of cardiac origin, shortness of breath and loss of reflexes in the legs. He drank daily 7 or 8 litres of beer. The only treatment was with 200 mg. vitamin B₁ daily given intravenously for 15 days with 100 mg. more given by mouth for the last 10 days. The effect was dramatic. The amount of urine passed rose to 5 litres daily and the patient lost 16 kg. in weight. Oedema and dyspnoea vanished, but the reflexes did not return. It is suggested that the condition may be at first reversible, but may later become chronic and resistant to vitamin B₁ as is more often found.—E. M. Hume.

2677

WOHL, M. G., BRODY, M., SHUMAN, C. R., TURNER, R. and BRODY, J. **Thiamine and cocarboxylase concentration in heart, liver, and kidney, of patients with heart failure.** *J. Clin. Invest.*, 1954, **33**, 1580-1586. [Nutrit. Project., Gen. Hosp., Philadelphia, Pa.]

Vitamin B₁ and cocarboxylase were estimated by the colorimetric method of Hochberg and Melnick (Abst. 3137, Vol. 14) in tissues from 12 subjects who had died of heart failure and from 10 without evidence of cardiac disease. Significantly lower values for vitamin B₁ and cocarboxylase were found in the heart and for vitamin B₁ in the liver from cardiac patients. In all tissues examined the values for vitamin B₁ and cocarboxylase

were lower for cardiac than for other subjects, but the differences were not significant for coarboxylase in the liver or for either substance in the kidneys.—A. M. Copping.

2678

JOHNSTON, M. The treatment of alcoholics in an outpatient clinic with adrenal cortex hormones and vitamin B₁. *Quart. J. Studies Alcohol*, 1954, 15, 238-245. [Adult Guidance Centre, Dept. Pub. Health, San Francisco.]

In 3 groups, 300 outpatients seeking treatment for alcoholism were given from 10 to 12 intramuscular injections of 50 mg. vitamin B₁, or of Lipo-Adrenal Cortex or of cottonseed oil. They had taken no alcohol for 3 days before treatment began. As criteria the rates of improvement of sleep, tension, shakiness, sweating, weakness, headache, nausea and eating were recorded. All signs had disappeared within 8 days. The differences between the groups were not significant, and it was considered that the giving of the injections, with sympathetic interest, had contributed to the result.—E. M. Hume.

2679

LARIZZA, P., SUARDI, L. and GOBBI, F. Influenza della coarboxilasi sull'escrezione urinaria dei 17-chetosteroidi, degli 11-ossi- ed 11-desossicorticoidi. *Ricerche in soggetti normali. [Influence of coarboxylase on the urinary excretion of 17-ketosteroids, 11-oxo- and 11-deoxycorticoids. Studies on normal subjects.] Acta vitaminol.*, 1954, 8, 214-225. [Ist. Clin. Med. Gen., Univ. Pavia.] French, English, German and Spanish summaries.

Corticosteroids were estimated in the 24-hr. urine of human subjects after one or more intravenous injections of 50 mg. coarboxylase. After a single injection the amount of 17-ketosteroids rose in 12 out of 20 normal subjects; the amount of 11-deoxycorticoids rose in 13 out of 20, and the amount of 11-oxycorticoids in 15 out of 20. When the same dose was given daily for 5 days, the tendency of the excreted steroids to increase was accentuated, at least temporarily. The increase was most marked with the 11-oxycorticoids. The results are considered to provide some evidence that the beneficial effects on asthma reported with coarboxylase are due to its action on the adrenal cortex.—E. M. Hume.

2680

JAMPOLER, I. and DESPERAK-SECOMSKA, B. Przyzwajalność u człowieka tiaminy i ryboflawiny z drożdży żywych i zabitych. [The availability for human beings of vitamin B₁ and riboflavin in living and killed yeast.] *Rocz. Państwowego Zakł. Hig.*, 1954, 5, 247-268. [Dział

Vol. 25, No. 2

Hig. Żywnienia PZH.] Russian and English summaries.

Five healthy adults were given a controlled diet with from 100 to 150 g. yeast daily. Yeast was killed by boiling for 1 min. Urinary and faecal excretion of vitamin B₁ and riboflavin was measured daily.

With killed yeast both the vitamins were quantitatively absorbed and did not appear in the faeces. With live yeast riboflavin was absorbed to a very small extent. Vitamin B₁ was found in the faeces in amounts that suggested that live yeast depletes the body of the vitamin. It was estimated that the daily ingestion of 100 g. live yeast for 3 or 4 days has the same effect as reducing the intake of vitamin B₁ by 25 per cent. (From summary.)—T. D. Bell.

2681

ŠNAJDER, K. Narodna shvatanja o prirodi pelagre. [The popular conception of the nature of pellagra.] *Zborn. Rad., Srpska Akad. Nauka*, 1954, 28 (Inst. Nutrit., No. 2), pp. 19. [Inst. Nutrit., Serb. Acad. Sci., Belgrade.] French summary.

The notions are those of the people of Kosovo-Metohija in Serbia. Pellagra is considered by them to be a simple deficiency disease arising primarily from restricted diet, especially with maize bread. The tendency is to treat the disease by adding to the diet foods known to have high nutritive value such as milk or meat. Use of tobacco is thought to be curative; for the skin condition ointments and fats are in common use. (From summary.)—D. Harvey.

2682

BORIĆ, D. Oplemenjivanje kukuruznog brašna u profilaksi pelagre. [Enrichment of maize flour in the prevention of pellagra.] *Zborn. Rad., Srpska Akad. Nauka*, 1954, 28 (Inst. Nutrit., No. 2), pp. 25. [Inst. Nutrit., Serb. Acad. Sci., Belgrade.] English summary.

Late in 1952 enrichment of whole maize meal with vitamin B₁, Fe, nicotinic acid, riboflavin and Ca was begun in Kosovo-Metohija, where the incidence of pellagra was known to be high. Of 5811 persons examined between 1949 and 1953, 831 adults and 730 children under 14 years of age were found to be affected. In April 1953, 309 of them were questioned, and 132 were making constant, 53 only intermittent, and 124 no, use of the enriched meal. Of the continuous users 32 were in the acute stage, 77 had passed it and 23 were, at the time, without signs whereas in previous spring seasons they had regularly had the disease. Of the intermittent users 30 were in the acute stage, 21 had passed it and 2 were seriously ill; none had escaped. For those making no use of the

enriched flour corresponding numbers were 81, 26 and 17 and again none had escaped. The value of flour enrichment is taken to have been proved even over the short period for which it had been practised. See also Abst. 2332, Vol. 24. (From summary.)—D. Harvey.

2683

AGARWAL, L. P. and DATT, K. **Role of nicotinic acid in healing of corneal ulcers.** *Amer. J. Ophthalmol.*, 1954, **37**, 764-767. [Dept. Ophthalmol., Med. Coll., Agra, India.]

Incisions were made in the cornea of rabbits, superficial in 3, and deep in 3. All the rabbits received a diet adequate in nicotinic acid, and 2 in each group received in addition 50 mg. nicotinic acid daily till the wounds healed. For the rabbits given and not given nicotinic acid, respectively, the healing of superficial wounds was complete in 3 and 5 days, and of severe wounds in 4 or 5 and 7 days. Scarring was less severe in those given nicotinic acid.

Of 57 patients with corneal ulcers given routine treatment, 20 had no other treatment, 20 had a daily intramuscular injection of 50 mg. nicotinic acid, and 17 received 25 mg. nicotinic acid subconjunctivally on alternate days. Results are reported separately for superficial and deep ulcers. For the former the average healing time in days, with range in brackets, was for untreated 9.9 (7 to 16), treated systemically 7.7 (3 to 14), treated subconjunctivally 5.4 (2 to 7). For the deep ulcers the values were for untreated 23.7 (12 to 39), treated systemically 19.9 (11 to 26), treated subconjunctivally 10 (4 to 15). Scar formation was reduced with nicotinic acid.

No significant change or deviation from the normal was observed in the blood value for nicotinic acid. See Abst. 2661, Vol. 25.—E. M. Hume.

2684

TRAVIA, L. **Significato biologico e clinico del rapporto lattoflavina libera: lattoflavina fosforilata nelle urine.** [Biological and clinical significance of the ratio of free riboflavin to riboflavin phosphate in the urine.] *Quad. Nutrizione*, 1953, **13**, 36-51. [Ist. Clin. Med. Gen., Univ. Rome.]

The author discusses his own and other work, and reaches certain conclusions. In the urine of normal human subjects riboflavin is present largely in the phosphorylated form when first secreted but, within the bladder or on standing after being passed, the proportion esterified steadily diminishes under the influence of a hydrolysing enzyme. The proportion phosphorylated is less if glucose has been given by mouth or riboflavin by intramuscular injection. In cirrhosis of the liver, experimental

hyperthyroidism and Graves' disease, and diabetes the proportion of free riboflavin is much larger.

E. M. Hume.

2685

ALBEGGIANI, A. **Reperti istologici ottenuti mediante biopsia-puntato del fegato in bambini affetti da malattie carenziali con particolare riguardo alla malattia da carenza di riboflavina.** [Histological results of liver biopsy in children with deficiency diseases, particularly with riboflavin deficiency.] *Pediatrica*, 1954, **62**, 175-208. [Clin. Pediat., Univ. Palermo.] French, English, Spanish and German summaries.

Histological examination was made of material from liver biopsies of 17 children aged from 3 to 24 months, and one of 7 years. Ten had clear signs of riboflavin deficiency; the remainder had less clear signs, with signs of other deficiencies, and with other diseases, niliary tuberculosis, pernicious anaemia of infantile type, severe protein deficiency, coeliac disease and sepsis. All individual case histories are given.

Every liver specimen showed fatty infiltration of varying degrees of severity. The primary conducting cause seemed to be diarrhoea, for the treatment of which aureomycin was the most satisfactory drug.—E. M. Hume.

2686

BEAN, W. B. and HODGES, R. E. **Pantothenic acid deficiency induced in human subjects.** *Proc. Soc. Exp. Biol. Med.*, 1954, **86**, 693-698. [Dept. Int. Med., State Univ. Iowa, Iowa City.]

Signs of pantothenic acid deficiency produced in 4 healthy young men by a purified basal diet lacking pantothenic acid and containing the antagonist, ω -methylpantothenic acid, included peripheral neuropathies such as paraesthesias, vertigo and burning feet, and biochemical abnormalities related to disturbances of adrenal cortical function. The symptoms were not immediately relieved by pantothenic acid alone, but consumption of a good mixed diet and a multiple vitamin mixture allowed complete recovery.

MAY, C. D. Vitamin B₆ in human nutrition: a critique and an object lesson. *Pediatrics*, 1954, **14**, 269-279. [Dept. Paediat., Coll. Med., State Univ., Iowa.]

Two recent reports of convulsions in infants due to vitamin B₆ deficiency (Absts. 3646, 3647, Vol. 24) are discussed critically with a review of the experimental findings in vitamin B₆ deficiency and consideration of conditions contributing to the development of deficiency in early infancy. Modifications and improvements in the manufacture of the proprietary food with which the signs of deficiency developed are suggested as the possible cause of the inadequate synthesis in the intestine, or the faulty absorption, or the increased requirement, which led to the state of deficiency. The importance of fully investigating all "idiopathic" seizures in infants is stressed.—A. M. Copping.

MURPHY, M. L., ELLISON, R. R., KARNOFSKY, D. A. and BURCHENAL, J. H. Clinical effects of the dichloro and monochlorophenyl analogues of diaminopyrimidine: antagonists of folic acid. *J. Clin. Invest.*, 1954, **33**, 1388-1396. [Chemotherap. Serv., Mem. Centre, New York.]

Some substituted diaminopyrimidines had an antagonistic effect towards folic acid as measured by the growth of *Lactobacillus casei*; pharmacological and clinical tests were, therefore, made on 2:4-diamino-5-(3':4'-dichlorophenyl)-6-methylpyrimidine and on 2:4-diamino-5-*p*-chlorophenyl-6-ethylpyrimidine. Adequate trials of the first compound were made on 34 patients with leucaemia or other malignant disease. Haematological improvement occurred in 3 children with leucaemia, but there was no other therapeutic benefit, and the drug was highly toxic. Its toxic effects were more prolonged than those of A-methopterin. In 2 patients very large doses of leucovorin were protective against the toxic effects. The monochloro-derivative, an antimalarial drug, produced toxic effects when given in very large doses. The possible action of the substituted pyrimidines in folic acid metabolism or in inhibiting the formation of citrovorum factor is discussed.

ROESEN, E. and OHLSEN, A. S. Achrestic anemia. Completely refractory megaloblastic anemia. A case followed for nearly four years. *Acta med. scand.*, 1954, **150**, 17-32. [Med. Dept., Cent. Hosp., Silkeborg, Denmark.]

The patient was studied for 4 years while being kept alive by repeated blood transfusions. The megaloblastic anaemia failed to respond to folic acid, vitamin B₁₂, several types of liver preparation, ascorbic acid, yeast, tyrosine, *p*-aminobenzoic acid and many other therapeutic measures.

D. Duncan.

2696

SCOTT, J. M. Therapy in the megaloblastic anaemias of pregnancy. *J. Obstet. Gynaecol. Brit. Empire*, 1954, **61**, 646-651. [Res. Dept., Royal Maternity Hosp., Glasgow.]

Most of the 37 women treated had red cell counts between 1.5 and 2 million. Vitamin B₁₂ gave a poor response in 5 women treated before and 3 treated after delivery, though 5 women (outside the series) with pernicious anaemia continued to be maintained by their vitamin B₁₂ treatment throughout pregnancy.

Crude liver preparations given by injection gave a good response with 5 out of 9 women before and 5 out of 7 after delivery. The patients resistant to liver or vitamin B₁₂, and others given no other treatment, responded well to folic acid. Many other patients required Fe also.

It is concluded that folic acid is the most suitable for treatment in megaloblastic anaemia of pregnancy and that a disturbance of folic acid utilisation and not a primary dietary deficiency was the cause of the condition.—D. Duncan.

2697

FERNANDES, J. J. Contribuição para o estudo de anemias na mulher Goesa durante a gravidez. [Anaemias of Goanese women during pregnancy.] *Arg. Escola Méd.-Cirurg. Goa*, 1953, Ser. A, No. 26, 39-71. [Centro Hematol. Hemoterap., Goa.]

Of 100 Goanese women on whom blood studies were made, 55 showed anaemia between the sixth and ninth month of pregnancy. The highest incidence was in the seventh month. Normocytic anaemia occurred in 14.5 per cent. cases, microcytic anaemia in 67.2 per cent. and macrocytic in 18.1, all of the last being hypochromic except for one case of macrocytic normochromic anaemia. In some the cause of anaemia was infections or parasites but in many it was dietary deficiency. The diet was generally poor and based on rice.

NIEWEG, H. O., FABER, J. G., DE VRIES, J. A. and STENFERT KROESE, W. F. The relationship of vitamin B₁₂ and folic acid in megaloblastic anaemias. *J. Lab. Clin. Med.*, 1954, **44**, 118-132. [Dept. Int. Med., State Univ. Groningen.]

Vitamin B₁₂ in blood serum was estimated with *Lactobacillus leichmannii* A.T.C.C. 7830, Strain 313 in the basal medium of Skeggs *et al.* (Abst. 1820, Vol. 20). Five different methods of treating the samples of serum were compared on 4 specimens of human serum. Folic acid was estimated with *Streptococcus faecalis* by the method of Tely and Elvehjem (Abst. 355, Vol. 15).

For 36 normal persons the values in μg . total vitamin B₁₂ per ml. ranged from 0.3 to 1.05, and for 17 patients with pernicious anaemia in relapse from 0.005 to 0.175; in other megaloblastic anaemias responding to vitamin B₁₂, serum values were low. In patients with megaloblastic anaemia resistant to vitamin B₁₂ the values were normal or even high.

The folic acid values in the blood of 43 normal persons ranged from 2.9 to 24.1 μg . per ml., with average 8.05. In 4 patients with sprue and in one with megaloblastic anaemia of pregnancy the folic acid value was low; these patients responded to folic acid but not to vitamin B₁₂. In 16 patients with pernicious anaemia in relapse, values for folic acid were normal in about half and low in the rest. In 7 untreated patients with pernicious anaemia, a single large injection of vitamin B₁₂ was followed at first by a fall in the concentration of folic acid in the blood, but, if observation was continued beyond 73 hr., an increase always occurred. Some results are given also for 14 patients with megaloblastic anaemia arising from nutritional causes and in pregnancy and from sprue; some of them responded to the one factor and some to the other.

In order to ascertain whether a patient is in need of vitamin B₁₂ or folic acid, estimation of vitamin B₁₂ in the blood is recommended. If the value is low, the vitamin should be given; if it is not low, folic acid should be given. The part played by the two substances in metabolism is discussed at some length. The authors are inclined at present to favour the view that vitamin B₁₂ and folic acid interact in the tissues as co-enzymes at different stages of nucleic acid synthesis, and that vitamin B₁₂, in addition, influences in some way the storage or intake of folic acid.

HORÁNYI, M. and ZÁDORY, E. Über den Nachweis des intrinsic factor und die Pathogenese der Anaemia perniciosa. [The intrinsic factor and pathogenesis of pernicious anaemia.] *Folia haematol.*, 1954, **72**, 297-310. [1. Int. Klin. Med., Univ. Budapest.] English, French and Russian summaries.

An account is given of 3 patients with severe megaloblastic, macrocytic anaemia, who had free gastric HCl. They responded well to injection of

N.A. and R., April 1955

liver extract. The gastric juice was tested for intrinsic factor by withdrawing from 80 to 100 ml. daily for 8 days from each patient and giving it to an untreated patient with pernicious anaemia at the same time as 100 g. minced meat. There was no reticulocyte response to the gastric juice of 2 of the patients and only a very small one to that of the third. The patients with pernicious anaemia who failed to respond subsequently responded fully to gastric juice from normal persons. Full case histories of the 3 patients are given. All had had much illness but no common predisposing factor could be recognised.—E. M. Hume.

2700

GIRDWOOD, R. H. Rapid estimation of the serum vitamin B₁₂ level by a microbiological method. *Brit. Med. J.*, 1954, ii, 954-956. [Dept. Med., Univ. Edinburgh.]

Growth of *Lactobacillus leichmannii*, measured by turbidity after incubation for 16 hr., was used to estimate vitamin B₁₂ in the blood serum of 36 patients with pernicious anaemia in relapse, 24 patients with other megaloblastic anaemias, 55 subjects with no anaemia, and 20 patients under treatment for pernicious anaemia. In pernicious anaemia patients values below 130 $\mu\mu\text{g.}$ per ml. were found unless treatment was in progress. In all others examined only 6 subjects had values as low as 130 $\mu\mu\text{g.}$ per ml. The test with *L. leichmannii* was useful as an aid to diagnosis in some cases of megaloblastic anaemia.—A. M. Copping.

2701

ALÉS, J. M. and VIVANCO, F. La determinación de la vitamina B₁₂ en la sangre de normales y enfermos. [Estimation of vitamin B₁₂ in the blood of the healthy and sick.] *Rev. clín. española*, 1954, 54, 72-75. [Inst. Invest. Méd., Madrid.] English, German and French summaries.

The content of vitamin B₁₂, estimated with *Lactobacillus leichmannii* in the blood of 20 normal subjects ranged from 50 to 560, with mean 226, $\mu\mu\text{g.}$ per ml. In an untreated patient with pernicious anaemia the value was 80, and in 2 patients under treatment with vitamin B₁₂ the values were 1520 and 1150.—A. M. Copping.

2702

CHOW, B. F. Vitamin B₁₂ and aging. *Nat. Vitamin Found., Inc., N.Y., Nutrit. Symposium Ser.* No. 9, 1954, 59-72. [Sch. Hyg. Pub. Health, Johns Hopkins Univ., Baltimore, Md.]

Serum values for vitamin B₁₂ were used as an index of absorption of the vitamin given orally to healthy young subjects and to subjects aged from

65 to 90. In young subjects 3 of 9 showed a marked rise in the value in response to a dose of 250 $\mu\text{g.}$, and 10 of 11 responded to 1000 $\mu\text{g.}$ Of 35 old subjects, 14 responded to the high dose and of 8 none to the low dose. The capacity of the gastric secretion to bind vitamin B₁₂ after a parenteral dose was two or three times as great in young subjects, which suggested a relative unsaturation with vitamin B₁₂ in the tissues of old people.

GLASS, G. B. J., LILICK, L. C. and BOYD, L. J. (with GUNNIS, C. and CORTI, L. G.) Metabolic interrelations between gastric intrinsic hematopoietic factor and vitamin B₁₂. 2. Further assays of vitamin B₁₂ in blood and urine of patients with pernicious anemia and following total gastrectomy by means of *Escherichia coli* mutant and *Euglena gracilis* technics. *Blood, J. Hematol.*, 1954, 9, 1127-1140. [Dept. Med., New York Med. Coll., Flower and Fifth Avenue Hosps., New York.] Interlingua summary.

A study of 3 patients with pernicious anaemia (*Bull. New York Med. Coll.*, 1952, 15, 17) had shown that much more vitamin B₁₂, given orally with intrinsic factor or by intramuscular injection, was absorbed from the intestine than was excreted in the urine. Seven patients were investigated in the present study with diets low in vitamin B₁₂; large test doses of the vitamin were given by mouth, alone or with intrinsic factor from pig's stomach. Vitamin B₁₂ was estimated in the blood and urine with a *Bacterium coli* mutant or *Euglena gracilis*.

In 2 patients after total gastrectomy but with no anaemia very high values were found in the blood within the first few hr. after a dose of 100 $\mu\text{g.}$ vitamin B₁₂. A considerable rise occurred in the blood of 4 patients with pernicious anaemia in relapse when 100 or 150 $\mu\text{g.}$ was given by mouth with intrinsic factor. A patient with nutritional macrocytic anaemia responded by a raised blood value when the vitamin was given with or without intrinsic factor. During the experimental period the urinary output of vitamin B₁₂ was in all cases less than 0.5 per cent. of the dose taken by mouth. After the haemopoietic response was established in patients with pernicious anaemia a definite increase occurred in the urinary excretion of vitamin B₁₂.—A. M. Copping.

2704

KILLANDER, A. B₁₂-vitaminhalt i serum vid akut och kronisk leukemi. [Vitamin B₁₂ in serum in acute and chronic leukaemia.] *Nord. Med.*, 1954, 52, 1513-1515. [Med.-Kem. Inst., Upsala.] English summary.

Vitamin B₁₂ was estimated, with *Euglena gracilis*, var. *bacillaris* as test organism, in serum from 5 patients with acute leukaemia, 7 with chronic myeloid leukaemia, 7 with chronic lymphatic leukaemia and 5 with cirrhosis of the liver. For comparison, 40 patients with pernicious anaemia had on the average 0.04 mμg. per ml. Two patients with cirrhosis and severe jaundice had values between 2 and 4 mμg. and 2 others had values above normal limits, which are shown as from 0.1 to 0.75 mμg. per ml. The patients with chronic myeloid leukaemia all had between 3 and 13 mμg. per ml. The values for the rest were within normal limits or were only slightly abnormal. No explanation of the high values can be offered at present.—I. Leitch.

SCHILLING, R. F. Symposium on basic and applied studies of the newer B-complex factors. Recent studies of intrinsic factor and the utilization of radioactive vitamin B₁₂. *Federation Proc.*, 1954, 13, 769-775. [Dept. Med., Med. Sch., Univ. Wisconsin, Madison.]

2706

MACLEAN, L. D. and BLOCH, H. S. Gastrointestinal absorption and urinary excretion of vitamin B₁₂-Co⁶⁰. *Proc. Soc. Exp. Biol. Med.*, 1954, 87, 171-174. [Dept. Surg., Med. Sch., Univ. Minnesota, Minneapolis.]

Urinary excretion of radio-active vitamin B₁₂ containing ⁶⁰Co was measured in human subjects during 24 hr. after a dose of 0.7 μg. by mouth followed by subcutaneous injection of 1000 μg. unlabelled vitamin B₁₂ to act as a flushing dose. The radio-active material could be extracted from the urine by *n*-butanol and was identified by chromatographic methods. Detectable amounts of radio-active vitamin B₁₂ were excreted only when the subcutaneous dose of inactive vitamin was given in addition to the radio-active dose by mouth. In 3 normal subjects from 20 to 29 per cent. of the oral dose of ⁶⁰Co, representing from 34 to 39 per cent. of the absorbed dose of vitamin B₁₂ was excreted in the urine within 24 hr. The test appeared to measure absorption of vitamin B₁₂ from the gut, not the absorption of breakdown products of the vitamin. It is considered that the test can be used to estimate intrinsic factor activity.—A. M. Copping.

2707

SWENDSEID, M. E., GASSTER, M. and HALSTED, J. A. Limits of absorption of orally administered vitamin B₁₂: effect of intrinsic factor sources. *Proc. Soc. Exp. Biol. Med.*, 1954, 86, 834-836. [Vet. Admin. Centre, Los Angeles, Calif.]

The absorption of vitamin B₁₂ from the gut was studied by giving the vitamin labelled with ⁶⁰Co and measuring the amount excreted in the faeces. Fasting normal subjects receiving 0.5, 2.0, 5.0 and 10.0 μg., absorbed a maximum of 1.65 μg. Administration of a test meal or of intrinsic factor did not increase the amount of the vitamin absorbed. In experiments with 2 gastrectomised patients, absorption of doses of 0.5 and 5 μg. vitamin B₁₂ was promoted by giving increasing amounts of intrinsic factor, but above the dose of 5 μg. a larger amount of intrinsic factor did not increase absorption beyond that attained in normal subjects.—A. M. Copping.

HEINRICH, H. C. Die biochemischen Grundlagen der Diagnostik und Therapie der Vitamin B₁₂-Mangelzustände (B₁₂-Hypo- und Avitaminosen) des Menschen und der Haustiere. 4. Resorption, Verteilung und Exkretion der B₁₂-Vitamine bei der oralen Therapie der perniziösen Anämie mit kristallisiertem Vitamin B₁₂ + "intrinsic factor". [Diagnosis and treatment of partial and complete deficiency of vitamin B₁₂ in man and domestic animals. 4. Absorption, distribution and excretion of vitamin B₁₂ in oral treatment of pernicious anaemia with crystalline vitamin B₁₂ and intrinsic factor.] *Klin. Wochenschr.*, 1954, 32, 867-878. [Physiol. Chem. Inst., Univ. Hamburg.]

The diagnosis and treatment of pernicious anaemia by oral administration of pure vitamin B₁₂ with a preparation of pig gastric mucosa to provide intrinsic factor are described. In patients with pernicious anaemia the low serum content and low urinary excretion of vitamin B₁₂, estimated with *Euglena*, rose gradually to normal in from 3 to 6 weeks after an initial dose of 30 μg. vitamin B₁₂, later reduced to from 2 to 10 μg. daily and all given with intrinsic factor. A dose of from 0.5 to 5 μg. daily with intrinsic factor maintained health for 1½ years. The content of vitamin B₁₂ in the urine was a better criterion of cure than in the serum where the value did not always rise to normal. The daily human requirement of vitamin B₁₂ is estimated as from 0.1 to 1 μg. Detailed case histories and charts for 4 patients are given in illustration.

Megaloblastic anaemias with normal serum content of vitamin B₁₂ and resistant to treatment with the vitamin, but which often respond to treatment with folic acid, are attributed to deficiency of that substance.—H. Chick.

BRÜCHER, H. Perorale Behandlung der perniziösen Anämie mit einem Kombinationspräparat aus Vitamin B₁₂ und Pylorusschleimhaut. [Treatment by mouth of pernicious anaemia with a combined preparation of vitamin B₁₂ and pyloric mucosa.] *Deutsch. med. Wochenschr.*, 1954, 79, 1726-1728. [Med. Poliklin., Univ. Heidelberg.]

Oral treatment of pernicious anaemia with a preparation of vitamin B₁₂ and powdered pyloric mucosa gave satisfactory results. Each tablet contained 5 µg. vitamin B₁₂ and 130 mg. pyloric powder; the doses given to the 7 patients described ranged from 4 to 10 tablets, according to the severity of the anaemia. The therapeutic action was assumed from the reticulocyte response, the increase in the number of erythrocytes, the Hb value, the results of repeated bone marrow tests, and, in some, estimation of serum Fe. In all the patients the marrow became completely normal. Subsequent treatment with high doses of a vitamin B₁₂ preparation given parenterally induced no further reticulocyte response.

2711

TAYLOR, W. H. Water diuresis in pernicious anaemia. *Clin. Sci.*, 1954, 13, 497-509. [Dept. Biochem., Radcliffe Infirmary, Univ. Oxford.]

The diuretic response to drinking 1 litre of water was significantly less in a group of 20 untreated patients with pernicious anaemia than in 16 treated patients, and in both groups it was significantly less than in 25 normal subjects. Diuretic response increased after effective treatment for 5 days with vitamin B₁₂, liver extract or folic acid. The delay was not related to Hb level. Dilution of plasma chloride, which occurs during normal water diuresis, was delayed in untreated pernicious anaemia. Dilution patterns were restored towards normal after treatment for about 7 days.

It is suggested that the delay in water diuresis results from a combination of delay in water absorption and in renal excretion.—F. C. Aitken.

CHOW, B. F., ROSEN, D. A. and LANG, C. A. Vitamin B₁₂ serum levels and diabetic retinopathy. *Proc. Soc. Exp. Biol. Med.*, 1954, 87, 38-39. [Dept. Biochem., Sch. Hyg., Johns Hopkins Univ., Baltimore, Md.]

A modified method which made it possible to measure very small amounts of vitamin B₁₂ was used to study 16 diabetic patients with, and 18 without, retinal lesions. The average amount of vitamin B₁₂ in the blood in µg. per ml. was 292 ± 24 for those with lesions and 162 ± 18 for those without. The difference is highly significant. The implications from the accumulation of vitamin B₁₂ in the blood are discussed with reference to its possible role in carbohydrate metabolism.

KAYE, K., CAUGHEY, R. H. and MCCRORY, W. W. Nitrogen balances on low nitrogen intakes in infants and the effects of gelatin supplementation with and without vitamin B₁₂ and aureomycin. *Pediatrics*, 1954, 14, 305-313. [Child. Hosp., Philadelphia, Pa.] Spanish summary.

After an adjustment period of at least 4 days on a low-protein diet, N balances were estimated in 5 infants for periods of 10 or 12 days. One infant with an intake of 70 mg. N per kg. bodyweight daily was in slightly negative balance; 2 with intakes of 110 mg. N per kg. were in slightly positive balance. Of the 2 infants with intakes of 100 mg. N per kg. daily, one was in slightly negative balance and the other was in N equilibrium. The last 2 were continued for a further 12-day period when N intake was doubled with gelatine and for a further 12-day period when 300 µg. vitamin B₁₂ and from 200 to 300 mg. aureomycin daily, were given in addition to gelatine. Gelatine increased N retention by 50 and 60 mg. per kg. daily; there was no further increase with vitamin B₁₂ and aureomycin.

Results of balance tests are given also for Na, K and Cl, the retention of which was increased in the subjects given gelatine. Retention of N and electrolytes was greater than would be expected from the gain in bodyweight that occurred during the periods of gelatine administration.

HUGHES, W. and MACLENNAN, D. C. Scurvy in old age. *Brit. Med. J.*, 1954, ii, 1149-1150. [Stapleton Hosp., Bristol.]

The patient was a man of 80 living alone and incapable of looking after himself.—E. M. Hume.

2718

DEWHURST, K. A case of scurvy simulating a gastric neoplasm. *Brit. Med. J.*, 1954, ii, 148-149. [Cowley Road Hosp., Oxford.]

The patient was a man of 72 living alone. He had many signs of scurvy. He was thought at first to have a prepyloric tumour, but when it had disappeared after treatment with ascorbic acid it was concluded that it must have been a sub-mucosal haematoma.—E. M. Hume.

2719

GRUSIN, H. and KINCAID-SMITH, P. S. Scurvy in adult Africans. A clinical, haematological, and pathological study. *Amer. J. Clin. Nutr.*, 1954, 2, 323-335. [Baragwanath Hosp., Johannesburg.] Spanish summary.

Scurvy was diagnosed in 40 Africans representing 0.13 per cent. of patients admitted to the hospital between August 1952 and July 1953 but, because mild cases were not admitted, its incidence among the African urban population must have been higher. It occurred mainly in spring and summer and almost always in men. Thirty patients, one a woman, were studied of whom 20 had had signs for from 1 to 4 weeks, 7 for from 2 to 3 months, and 3 for from 2 to 3 years. The clinical signs and histopathological changes were predominantly in the leg muscles; they are described in detail.

Some findings deserved special mention. Scurvy frequently occurred when fruit and green vegetables were plentiful and cheap, but the diet consisted mainly of maize porridge, bread and small amounts of meat and cooked vegetables. Extensive chronic changes in patients with thin legs,

when the skin and subcutaneous tissue became closely bound together, might persist for many months and still, to some extent, respond to treatment with ascorbic acid. X-ray examinations were made of 15 patients and 4 showed signs of osteoporosis; in Africans in whom such a finding might be otherwise inexplicable, scurvy might be the cause. Nineteen patients had gum lesions but none had haemorrhagic effusions or gross bleeding from bowel or kidney. The changes in Hb value were not related to the severity of tissue haemorrhage, and it is considered that they, together with an oedema which could not be related to heart failure, renal disease or anaemia, may have been due, to some extent, to fluctuations in blood volume. Blood proteins were low, particularly the albumin fraction.—D. Harvey.

2720

CAMPBELL, A. M., GRASS, R. J., HACKER, D. B., HOTOPP, M. and LANTZ, E. M. The relation of vitamin C to the condition of the gums of New Mexico school children in selected areas. *New Mexico Agric. Exp. Stat. Bull.* No. 380, June 1953, pp. 21.

Schoolchildren with sore or spongy gums from 6 different schools, 2 in each of 3 counties, were physically examined, their diets were recorded and ascorbic acid in the serum was estimated 4 times at intervals of 6 weeks. Diet was in general low in ascorbic acid, and more than half of the 231 children examined had subnormal values of less than 0.4 mg. ascorbic acid per 100 ml. serum.

After the first examination, 100 mg. ascorbic acid was given every school day to children from one school in each county. Serum ascorbic acid was normal at the second examination and the dose was altered according to the condition of the gums; in the other children the serum value continued to fall until ascorbic acid was supplied. The condition of the gums improved slowly. Redness of the eyes was referred to deficiency of ascorbic acid.—A. Hepburn.

KAUS, H. Genese und diagnostischer Wert von unter Saugglöcken entstandenen Hautblutungen. [Genesis and diagnostic value of haemorrhages of the skin produced by cupping.] *Ztschr. ges. exp. Med.*, 1954, **124**, 448-464. [Hautklin., Städt. Krankenanst., Aachen.]

The paper deals chiefly with the physical properties of the skin tissues, particularly their elasticity, and the gross errors which differences in them introduce into any method using the appearance of petechiae under negative pressure as a criterion of capillary resistance.—E. M. Hume.

2723

JONXIS, J. H. P. and HUISMAN, T. H. J. **Amino aciduria and ascorbic acid deficiency.** *Pediatrics*, 1954, **14**, 238-244. [Dept. Paediat., Univ. Groningen.] Spanish summary.

The amount of amino-acids in the urine of 2 infants with scurvy was abnormally high, but became normal during administration of ascorbic acid for 3 or more weeks. The most pronounced increase was in taurine, threonine, serine, glycine, tyrosine, histidine, lysine and a β -alanine complex shown by paper chromatography to consist largely of β -aminoisobutyric acid. As ultrafiltrates of plasma from 2 scorbutic infants contained only normal amounts of amino-acids, the excessive amount in scorbutic urine was attributed to defective tubular re-absorption in the kidneys.

A. Hepburn.

2724

HUISMAN, T. H. J. **The concentration of different amino acids in the blood plasma in children suffering from rickets and scurvy.** *Pediatrics*, 1954, **14**, 245-253. [Child. Hosp., Univ. Groningen.] Spanish summary.

Plasma filtrates from children, 2 with scurvy, 3 with rickets and 4 normal, and from 2 normal adults, were analysed for amino-acids by cation exchange chromatography before and after hydrolysis. Most of the common amino-acids were present in moderately reasonable amounts but hydroxyproline was not found. Asparagine and glutamine were present in large amounts and several unknown substances were detected. The concentration of alanine, valine, leucine, phenylalanine and histidine was greater after hydrolysis. Plasma from scorbutic and rachitic children was not significantly different in amino-acid composition from that of the normals.—A. Hepburn.

2725

DAS GUPTA, N. K. **Biochemical studies with prothrombin, fibrinogen, ascorbic acid and calcium in relation to some haemorrhagic conditions. Coagulation of the blood.**

Ascorbic acid and its relation to scorbutic and non-scorbutic haemorrhages. Method for estimation of fibrinogen in plasma. Method for estimation of ascorbic acid and calcium in plasma. Prothrombin, fibrinogen, ascorbic acid and calcium levels in peptic ulcer. Method for estimation of ascorbic acid and calcium in plasma. *Calcutta Med. J.*, 1953, **50**, 341-347; 380-386; 418-421; 460-472; 1954, **51**, 19-30; 57-66; 100-101.

Prothrombin time, fibrinogen and ascorbic acid were estimated in plasma and Ca in serum from 50 normal males and 15 normal females. Age and sex apparently had no effect and the average results with ranges were, prothrombin time 20.3 (17.3 to 24.6) sec., fibrinogen 0.265 (0.200 to 0.360) g. per cent., ascorbic acid 0.48 (0.0 to 1.34) mg. per cent. and Ca 9.50 (8.34 to 11.25) mg. per cent.

In 9 patients with enteric fever studied, prolonged prothrombin times of from 33.2 to 96.3 sec. were found, especially when there was haemorrhage or much toxæmia. Two patients had little fibrinogen; the values ranged from 0.228 to only a trace and were not related to extent of haemorrhage. Patients with low blood prothrombin values and very low fibrinogen died. The initial average value for ascorbic acid was 0.14 mg. per cent.

Among 15 patients with liver diseases, bleeding with jaundice was associated with prolonged prothrombin times, 42.5 to 90.6 sec., but some with such times, from 60 to 70 sec., had no haemorrhage. Haemorrhage stopped as the prothrombin time decreased. In conditions associated with irritation of the liver like early cirrhosis and early stages of infective jaundice, both prothrombin time and fibrinogen value improved at first, and deteriorated later with the progress of liver damage. The average initial value of ascorbic acid was 0.29 mg. per cent.

High values for prothrombin time and low values for fibrinogen, 69.3 sec. and 0.06 g. per cent. at the extremes, were found in 8 of 10 patients with malignant disease. The abnormality was more pronounced with the more rapidly growing tumours and was independent of metastasis in the liver. Ascorbic acid averaged 0.12 mg. per cent.

In 9 hypertensive subjects with or without haemorrhage only 2 had a low value for blood prothrombin; it was slightly high in 2 patients with thrombosis. Fibrinogen tended to be low, ranging from 0.119 to 0.213 g. per cent. The average initial ascorbic acid was 0.22 mg. per cent.

Results are given also for patients with kala-azar, pulmonary tuberculosis and peptic ulcer.

In all the haemorrhagic diseases mentioned, the serum Ca value was normal. The values for ascorbic acid and Ca were not related to the extent of haemorrhage.—A. Hepburn.

CLAYTON, B. E., MCSWINEY, R. R. and PRUNTY, F. T. G. **Metabolism of dehydroascorbic acid and the effect of adrenocorticotrophic hormone and cortisone.** *Biochem. J.*, 1954, **58**, 542-552. [Dept. Chem. Pathol., St. Thomas's Hosp. Med. Sch., London, S.E.1.]

Dehydroascorbic acid had some antiscorbutic effect and prolonged life when injected into guinea-pigs receiving a scorbutic diet; it increased the amount of ascorbic acid in the tissues, but most of that injected was not accounted for. It did not appear in the tissues or urine, which contained increased amounts of oxidation products. In many animals loss of fur, respiratory difficulty and paralysis of the hind limbs preceded ultimate death. Post-mortem examination showed fatty livers but no sign of scurvy.

In 2 human subjects previously given 600 mg. ascorbic acid daily, the same amount of dehydroascorbic acid given by mouth did not alter the urinary excretion of ascorbic acid. The sample of dehydroascorbic acid used was unsuitable for injection into human subjects. Intramuscular injections of dehydroascorbic acid methanolate (readily dissociable in water to dehydroascorbic acid and methanol) into a subject saturated with ascorbic acid decreased by one-third the excretion of ascorbic acid and by one-half that, taken together, of ascorbic acid, dehydroascorbic acid, diketogulonic acid and possibly unidentified impurities, as measured by the method of Roe and Kuether (Abst. 261, Vol. 13), and subsequently referred to as R. and K. material. The amount of ascorbic acid in the plasma and of dehydroascorbic acid in the plasma and urine was little changed. Similar injections into a subject moderately depleted of ascorbic acid increased the ascorbic acid in plasma and urine. The R. and K. material in the urine rose promptly.

The metabolism of ascorbic acid or dehydroascorbic acid in guinea-pigs was unaltered by administration of adrenocorticotrophic hormone or cortisone acetate. In human subjects into whom dehydroascorbic acid was injected, the hormone caused a transitory increase in ascorbic acid, and in R. and K. material excluding ascorbic acid in 1 subject, a sharp rise of R. and K. material excluding ascorbic acid in another, and a significant small increase in the excretion of dehydroascorbic acid in a third. It was concluded that adrenocorticotrophic hormone does not retard the reduction of dehydroascorbic acid to ascorbic acid regularly or significantly, especially in guinea-pigs.

BOSCOTT, R. J. and COOKE, W. T. **Ascorbic acid requirements and urinary excretion of *p*-hydroxyphenylacetic acid in steatorrhoea and macrocytic anaemia, with a description of the paper-chromatographic technique for identification of hydroxyphenylic acids.** *Quart. J. Med.*, 1954, **23**, 307-322. [Dept. Anat., Univ. Birmingham.]

In patients with steatorrhoea abnormally large quantities of ascorbic acid had to be administered before significant amounts were excreted in the urine. None of the usual signs of clinical scurvy was present, but refractory macrocytic anaemia was frequently found. A study of the acidic *p*-hydroxyphenylic compounds in the urine was made by paper chromatography, the technique of which is fully described; it showed that the chief abnormal component was *p*-hydroxyphenylacetic acid. The clinical and chemical significance of the findings is discussed. There appeared to be a defect in tyrosine metabolism which was less rapidly rectified by ascorbic acid in patients with steatorrhoea than in other subjects. The defect was not due to a primary dietary deficiency or to difficulty of absorption. It is considered that the refractory macrocytic anaemia, the abnormal ascorbic acid utilisation and the disturbed tyrosine metabolism are manifestations of a common underlying metabolic error. Haematological response to ascorbic acid is reported in 3 patients, and the relationship of ascorbic acid to haemopoiesis is discussed.—M. B. Richards.

SPIEGEL-ADOLF, M., BAIRD, H. W., III, SZEKELY, E. G. and WYGIS, H. T. **Cerebrospinal fluid studies in infant children with cerebral palsy and other neurologic disorders.** *Pediatrics*, 1954, **14**, 215-221. [Dept. Colloid Chem., Sch. Med., Temple Univ., Philadelphia, Pa.] Spanish summary.

The extinction coefficient of cerebrospinal fluid from 100 children with cerebral palsy or other neurological disorders was studied by spectrography in ultraviolet light. Ascorbic acid and protein, the principal constituents of cerebrospinal fluid with maximum absorption near 265 m μ , were estimated chemically and from the results the so-called D value, which is a measure of the other substances absorbing at 265 m μ , was obtained.

The average D values for the sick group, including children with birth trauma, cerebral palsy, mental retardation, hydrocephalus and convulsions, were significantly higher than normal except in the case of convulsions. Previous work

N.A. and B., April 1955

(Spiegel-Adolf and Wycis, *Confinia Neurol.*, 1951, 11, 87; Windle et al., *Surg. Gynecol. Obstet.*, 1944, 79, 561) suggested that a high D value was evidence of cellular damage. Mentally retarded children had high D values which were related inversely to the degree of mental development.

In normal newborn infants there was more protein and ascorbic acid in the cerebrospinal fluid than in older children and adults. Since the concentration of protein in the blood is lower than in adults the finding was a sign of greater permeability of the blood-brain barrier. In children with neurological signs the values for protein in the cerebrospinal fluid had a wider deviation than in normal children, the respective values being 35.28 ± 26.97 and 28.50 ± 6.06 mg. per cent.

GLANDER, R. and LANDBECK, G. Die Wirkung von Vitamin K₁ auf den Prothrombin- und Faktor VII-Mangel des Neugeborenen. [Effect of vitamin K₁ on deficiency of prothrombin and factor VII in the newborn.] *Ztschr. Kinderheilk.*, 1954, 75, 392-400. [Kinderklin., Univ. Hamburg, Eppendorf.]

Thirty infants were given by mouth, from the age of 1 or 2 days, 10 mg. daily of a synthetic preparation of vitamin K₁, Konaktion (Hofmann-La-Roche), to determine its influence on prothrombin and Factor VII. Estimations made at the age of 3 or 4 days, when prothrombin is known to reach its minimum in blood, showed that in 13 infants the coagulation time was entirely, and in 6 others nearly, normal. Such results could not be attained with the water-soluble vitamin K₁ preparations hitherto available. No difference in response was found between premature and full-term infants. Disturbances of absorption and immaturity of the liver are suggested as possible explanations of the complete lack of effect in the other 11 infants.—M. B. Richards.

2731

GEILL, T., LUND, E., DAM, H. and SØNDERGAARD, E. Studies on the efficiency of vitamin K₁ in small doses as antidote against anticoagulants of the dicoumarol type. *Scand. J. Clin. Lab. Invest.*, 1954, 6, 203-209. [Dept. Med., De Gamles By (Old Peoples Town), Copenhagen.]

Of 40 normal subjects, 22 received dicoumarol by mouth and 18 2-p-chlor-phenyl-1-3-indandione in doses sufficient to depress the concentration of prothrombin and proconvertin below 10 per cent. of normal. Vitamin K₁ and menadiol sodium bisulphite were administered both intravenously and by mouth. Menadiol sodium sulphate was injected intramuscularly.

Vol. 25, No. 2

Vitamin K₁ raised the concentration of prothrombin and proconvertin markedly when given intravenously, more slowly when given by mouth. The 2 derivatives of menadione had only a slight effect even in doses of 100 mg. Intravenous injection of from 10 to 20 mg. vitamin K₁ in the form of a sterile aqueous colloidal solution gave a therapeutic effect within 2 hr. and is recommended for raising the concentration of prothrombin and proconvertin where dicoumarol anticoagulants have produced serious haemorrhage. Higher doses are unnecessary and may be dangerous by favouring thrombosis.—A. Hepburn.

2732

CHALMERS, J. N. M., DIXON, M. F. and POLACK, W. Antagonistic effect of oral vitamin K₁ on the action of ethyl biscoumacetate and phenylindanedione. *Brit. Med. J.*, 1954, ii, 956-959. [Haematol. Dept., St. George's Hosp. Med. Sch., London.]

The effect of a single oral dose of 100 mg. vitamin K₁, 2-methyl-3-phytyl-1:4-naphthoquinone, was tested on healthy subjects taking regular therapeutic doses of the anticoagulant ethyl biscoumacetate or phenylindanedione. The vitamin was dissolved with an emulsifying agent and given with fruit juice. The prothrombin activity of the blood, reduced by the anticoagulant drugs, rose again immediately after vitamin K₁ was given. In patients with thrombo-embolic diseases under treatment by anticoagulant drugs, small doses of vitamin K₁ modified the low blood prothrombin value and controlled the therapeutic process.

MELLANBY, M. and MELLANBY, H. (with KELLEY, M.) **Dental structure and caries in 5-year-old children attending L.C.C. schools (1949 and 1951).** *Brit. Med. J.*, 1954, **ii**, 944-948. [Nutrit. Building, Nat. Inst. Med. Res., Mill Hill, London.]

Results of the 1951 survey, which covered 1395 children, are tabulated and shown graphically along with those of the 1949 survey, hitherto published only in summarised form (Abst. 2730, Vol. 20). Not much change was found, respective figures for 1949 and 1951 being as follows: percentage of children free or almost free from caries, 24.9, 23.5; percentage of caries-free teeth, 73.3, 72.5; percentage of teeth not showing hyperplasia, 32.0, 42.3.

It is suggested that the increase in the incidence of caries since 1947 may have been due to consumption of less of the protective foods such as milk, eggs and cod liver oil and more of oatmeal and other cereals as the food controls were lifted. The increases in sugar and sweet rations are thought to have been too small to account for it, either directly or by reducing the consumption of other foods.—W. M. Deans.

2740

PARFITT, G. J. **The apparent delay between alteration in diet and change in caries incidence: a note on conditions in Norway reported by Toverud.** *Brit. Dent. J.*, 1954, **97**, 235-237.

Toverud's conclusions (see Abst. 2722, Vol. 19 and Titles 2723, Vol. 19 and 4245, Vol. 20) were criticised by Sognnaes (Abst. 5460, Vol. 19), who showed that in certain age groups the fall in the incidence of caries continued after the rise in consumption of sugar. An attempt has been made to reconcile these findings. Hypothetical graphs of caries rates have been constructed, beginning with the incidence recorded in 1937 and applying to each age an equal incidence which, however, varied from year to year in relation to the consumption of sugar. The resulting curves have a close resemblance to Toverud's graphs and show also that in the 6-year-old group a time lag was possible before a rise in caries incidence occurred.

GRAINGER, R. M. and REID, D. B. W. **Distribution of dental caries in children.** *J. Dent. Res.*, 1954, **33**, 613-623. [Div. Dent. Res., Univ. Toronto, Ont.]

In this investigation into the distribution of carious tooth surfaces in children the surfaces were divided into two classes, smooth and pitted. The statistical methods, which are developed at some length, show that the negative binomial distribution fits the case for smooth surfaces. This agrees with the idea that dental caries is a chance phenomenon where susceptibility varies between individuals. Complications are encountered in the analysis of the carious pitted surfaces. It becomes necessary in the first place to consider one side of the mouth only. The differing susceptibility

between pitted tooth surfaces has also to be considered, as well as the correlation between some pitted surfaces; for example, with young children, the occlusal surfaces of the upper and lower first molars are responsible for most of the caries.

It is considered that with very young age groups the number of tooth surfaces exposed to risk varies too much to enable a fit to be made, but with older children where the number of tooth surfaces is relatively constant, a model, assuming that the proportion of pitted surfaces follows a beta distribution, enables the numbers of children with a given number of carious pitted surfaces to be estimated with satisfactory approximation to the observed numbers.—A. W. Boyne.

WESPI, H. J. Fluor-Jodsalz zur Krepf- und Cariesbekämpfung. [Fluorinated and iodinated salt in prophylaxis of goitre and caries.] *Schweiz. med. Wochenschr.*, 1954, **84**, 885-890. [Geburtshilf. Gynäkol. Abt., Kantonsspital, Aarau.] French and English summaries.

The risks of toxicity are discussed, but no harm is expected to result from the addition of NaF as well as KI to salt. Addition of fluoride to water or milk supplies for scattered Alpine communities is impracticable. Its addition to salt sold in packets is preferable but, as this costs more than salt sold loose, the NaF may not reach the poorer people. It is recommended that 200 mg. NaF and 10 mg. KI per kg. salt should be added. When low-salt diets are required an aqueous solution containing 5 g. NaF and 0.5 g. KI per litre should be used to supply 500 µg. F and 100 µg. I daily.—E. M. Hume.

2748

HORASAWA, I., HAGIWARA, K. and NAKAJIMA, F. On the fluoride in the drinking water of two villages in Nagano Prefecture and its relation to the occurrence of mottled enamel. *Bull. Inst. Pub. Health, Tokyo*, 1952, **2**, No. 2, 24-26 (English). [Dept. Sanit. Engin., Inst. Pub. Health, Tokyo.]

The occurrence of mottled enamel was surveyed in the villages of Tokiwa and Matsukawa in Nagano Prefecture. The villages are in the middle of rice fields. The water drunk comes chiefly from the Takase river, which rises in the Japan Alps and has a fluorine content of from 0.35 to 0.8 p.p.m., but some people got water from other streams or wells with from 0.04 to 0.24 p.p.m. Between 300 and 400 junior high-school children were examined in each of the villages and the percentage incidences of mottled enamel were 43 and 58, respectively. Corresponding percentages for about 750 elementary schoolchildren from each of the villages were 41 and 50. For small samples of individuals from different areas in Tokiwa village the incidence ranged from 19 to 60 per cent. It is noted that mottled enamel seemed to occur with a concentration of F in the water lower than that commonly reported. Survey of the land showed that water high in F from hot springs entered the Takase river not very far above the villages.—E. M. Hume.

2749

KAWAHARA, H. and KAWAHARA, K. The new method of classifying mottled teeth based on fluorine content in drinking water. *Shikoku Acta Med.*, 1954, **5**, No. 3, 16-20. [Dept. Int. Med., Sch. Med., Univ. Tokushima.] Japanese summary.

A system for the classification of mottling of teeth according to 4 types of change with 5 degrees of each is described and illustrated. The need for distinguishing changes similar to mottling and not caused by fluorine is emphasised. There is brief mention of some evidence that dental fluorosis occurs more readily in Japanese than in Americans when they are drinking water with similar contents of F.—D. Harvey.

2750

LEONE, N. C., SHIMKIN, M. B., ARNOLD, F. A. (Jr.), STEVENSON, C. A., ZIMMERMAN, E. R., GEISER, P. B. and LIEBERMAN, J. E. **Medical aspects of excessive fluoride in a water supply.** *Pub. Health Rep., Washington*, 1954, **69**, 925-936. [Nat. Inst. Dent. Res., Nat. Inst. Health, Pub. Health Serv.]

Two population groups were studied, one of 116 persons in Bartlett, Texas, where the water supply contained about 8 p.p.m. F, and the other of 121 persons in Cameron, also in Texas, where the F content of the water was only 0.4 p.p.m. The criterion for participation was 15 years' residence before the first examination made in 1943. The second examination was made in 1953. This paper deals with the statistical analysis of the results; clinical impressions will be reported later.

Of the 237 persons originally seen, 71 per cent. were available in the towns at the time of the re-examination; 8 per cent. had died in the interval. The number who had moved elsewhere was 47, of whom 37 were examined in 1953; the remaining 10 were not examined, but were interviewed and

gave no history of serious illnesses. In 1953 the average duration of exposure to high F intake was 36.7 years. Eighteen months before the second examination a defluoridation plant had been installed at Bartlett, but its use was thought unlikely to have affected the findings. The data are fully tabulated.

Statistically significant differences between the communities were found only for the incidence of cardiovascular disorders other than uncomplicated hypertension, which was higher, and for blood white cell counts, which were lower, in Cameron than in Bartlett. Dental fluorosis was common in Bartlett.—D. Harvey.

ROBINSON, C. H. The low cholesterol, low fat diet. *Amer. J. Clin. Nutr.*, 1954, 2, 353-355. [Dept. Food Nutr., Coll. Home Econ., Drexel Inst. Technol., Philadelphia, Pa.]

Details are given of a diet low in cholesterol and fat but providing allowances of other nutrients recommended for men or women. It includes, daily, 5 cups skimmed milk, 5 oz. lean beef, veal, lamb, poultry or fish, 1 serving whole-grain or enriched cereal, 6 slices whole-grain or enriched bread, 1 medium potato and servings of fruits; extra energy is provided by sugar, jelly, jam or greater amounts of vegetables, fruits, cereals or breads. Foods high in cholesterol and fat, and therefore to be avoided, are listed and sample menus are described. It is emphasised that the value of such a diet in vascular disease has not been established; it should not be used indiscriminately.—G. F. Garton.

OLMSTREAD, E. G., CASSIDY, J. E. and MURPHY, F. D. Nutritional value of beer with reference to the low salt diet. *Amer. J. Clin. Nutr.*, 1954, 2, 392-395. [Dept. Med., Sch. Med., Marquette Univ., Milwaukee, Wis.] Spanish summary.

The average Na content of 25 representative samples of United States beer was 6.95 mg. per 100 g. Urinary excretion of Na by 4 patients was measured while they were on a hospital, low-Na, diet and when they were on a low-Na diet in which one-quarter of the energy was supplied by a beer containing 2.9 mg. Na per 100 g. The results indicated that more accurate salt restriction was obtained on the diet which contained beer.

LINDEBOOM, G. A. Hyponatraemie bij decompensatio cordis. [Low blood sodium in cardiac decomposition.] *Nederland. Tijdschr. Geneesk.*, 1954, 98, 3206-3217. [Afd. Inw. Ziekten, Vrije Univ., Weesperplein Ziekenhuis, Amsterdam.] English summary.

A distinction is drawn between "low-salt syndrome" which arises acutely from loss or deliberate deprivation of salt, and "chronic dilution with low blood sodium". Both occur in cardiac decompensation, with oedema. In the former total body Na is low, in the latter normal or high. NaCl relieves the former. But the latter disturbance is not relieved by NaCl, nor does deprivation of salt relieve the oedema, which is progressive. Urea and K have sometimes been found helpful.—I. Leitch.

- JACOBI, H. G. (with KAUFMAN, M. and OGATA, T.) The food consumption of juvenile diabetics. Evaluation of diets used at home and at summer camp. *Amer. J. Clin. Nutr.*, 1954, 2, 343-347. [111 East 80th St., New York 21.] Spanish summary.

The feeding was studied of 58 diabetic boys and 62 diabetic girls aged 10 to 17 years at home and in a camp for diabetic children which they attended. Data are given for prescribed and actual home diets, for the final camp diets and for the corresponding insulin dosages in a representative group of campers. Most of the children were taking carbohydrate in great excess; only about one-fifth of the boys and one-third of the girls followed their prescribed diet. In many instances the prescribed home diet was considered to be inadequate in energy content to meet the needs of active and growing children. There was ignorance among children and parents of food values, and instructions from their doctors or dietitians had been inadequate.

In a group of 37 of the children who were on an unrestricted diet before attending the camp about one-half took a diet considered, by recommended standards, to be normal for their energy needs; the remainder were eating to excess, some more than twice these amounts.—G. F. Garton.

GASTRO-INTESTINAL CONDITIONS

2769

- LEWIS, M. N., MURRAY, M. A. and ZOLLINGER, R. M. Dietary regimen following partial gastric resection. *J. Amer. Dietetic Assoc.*, 1954, 30, 852-855. [Dept. Dietetics, Ohio State Univ. Hosp., Columbus.] Eighty-three patients who had undergone partial gastric resection less than 1, or 1 to 5 years

previously were interviewed. About one-third had lost weight and about one-quarter reported discomfort after ingestion of food. A study in hospital of the diet of 26 patients immediately after operation showed that the feeding programme followed was not suitable for most of them and a new and more acceptable feeding plan was devised. This consisted of 5 meals of foods low in volume, concentrated in food value and of suitable temperature and consistency. Sample menus are given.

- ROCHA, A. Consideraciones dieteticas en el "dumping" de los gastrectomizados. [Diet in "dumping" after gastrectomy.] *Rev. española Enferm. Apart. digest. Nutricion*, 1954, 13, 444-446. [Serv. Med. Gen., Hosp. S. Cruz y S. Pablo, Barcelona.]

Since jejunitis is the chief cause of digestive disturbance after gastrectomy, the aim must be to provide an adequate diet which will avoid inflammation of the jejunum. Particular care must be taken in the early days after operation, since jejunitis, once established, can lead to acceleration of gastric evacuation. As milk in liquid form passes rapidly into the intestine, which is not provided with enzymes for its digestion, it should be given coagulated with lactic acid, or as yoghurt. Meat containing excessive collagen, and vegetable cellulose are to be avoided, and fats should be given with caution since their excessive use leads to steatorrhea, which can cause intestinal irritation. The diet must be progressively regulated both quantitatively and qualitatively before permitting an uncontrolled diet, which might be the first step towards the establishment of "dumping" in the patient.—M. B. Richards.

- DOLL, R. and PYGOTT, F. Clinical trial of robaden and of cabbage juice in the treatment of gastric ulcer. *Lancet*, 1954, 267, 1200-1204. [Statistical Res. Unit, Med. Res. Council.]

Twenty-four patients were given 1 litre fresh cabbage juice daily for 3 weeks; 24 controls were treated similarly but without cabbage juice; 32 patients were given robaden or (robuden) daily for 3 months and 32 controls were treated similarly but without robaden. All of these patients were kept in bed for the first month and were outpatients during the second and third months. Fifty outpatients were given robaden daily for 1 year and 50 controls received no robaden. Progress in all groups was assessed subjectively and radiographically. No evidence was obtained that either cabbage juice or robaden influenced the healing of gastric ulcers.—F. C. Aitken.

THYROID DISEASE

2777

- THALMANN, A. Die Häufigkeit der Struma maligna am Berner pathologischen Institut von 1910-1950 und ihre Beziehung zur Jodprophylaxe des endemischen Kropfes. [Frequency of malignant goitre at the Berne Pathological Institute, 1910-1950, and its relation to iodine prophylaxis of endemic goitre.] *Schweiz. med. Wochenschr.*, 1954, **84**, 473-478. [Pathol. Inst., Univ. Berne.]

The world literature on the incidence of malignant goitre is reviewed. Records of material from operations and post-mortems, investigated histologically between 1910 and 1950 in the Berne Pathological Institute, were examined. Not all goitres were examined histologically, so total figures cannot be given. The 10 years from 1917 to 1927 are taken as representative of the period before the introduction of I prophylaxis, and those from 1940 to 1950 of the period after it. Of 2823 goitres removed by operation in the first 10 years 6.94 per cent. were malignant, and of 7457 removed in the second 10 years, 5.44 per cent. The percentage of malignant goitres found at post-mortem remained almost constant. There was not, therefore, any evidence that the adoption of general I prophylaxis had influenced the incidence of malignant goitre in either direction, though there was some evidence that the type had changed, papilloma and large-celled adenoma having become more frequent, and sarcoma and carcinoma less so.

A warning is given of the possible goitrogenic effect of fluorine administered for prophylaxis against dental caries.—E. M. Hume.

2778

- DARDEL, G. El bocio y el contenido de yodo en el agua potable. [Goitre and the iodine content of the drinking water.] *Arch. urug. Med.*, 1954, **44**, 13-37. [Univ. Berne.]

The relation between the incidence of goitre and the I content of the water supply is reviewed; reports from Switzerland and some other countries during the past 150 years are considered. The problems of treatment are discussed and a protective dose of 5 mg. KI per kg. edible salt is suggested. There is probably no endemic goitre in Uruguay though sporadic cases occur.

A. M. Copping.

2779

- WILSON, D. C., GRUNDY, H. M., STEEL, R. W. and EDDY, T. P. Goitre in Sierra Leone. *Trans. Roy. Soc. Trop. Med. Hyg.*, 1954, **48**, 481-489. [Lab. Human Nutrit., Univ. Oxford.]

Findings are tabulated on the incidence of goitre among adults, 1068 indigenous inhabitants and 53 immigrants and among 79 children, 14 of whom were natives of the coastal area and 65 natives of

the Kono district in the west. Information about their accustomed diets was obtained and data were available on the I content of 26 different water supplies. It is concluded that the distribution of the disease follows that of pre-Cambrian granite rocks and of water supplies with less than 1.0 µg. I per litre. In these parts the seasonal scarcity of red palm oil and the pollution of water supplies may also play a part.—D. Harvey.

2780

DEMAEYER, E. M. and VANDERBORGH, H. L. Enquête sur le goitre endémique au Ruanda. [Inquiry into endemic goitre in Ruanda.] *Ann. Soc. belg. Méd. trop.*, 1953, **33**, 579-592. [Inst. Recherche Sci. Afrique Centrale, Kivu, Belg. Congo.] English and Flemish summaries.

A survey was made of groups of about 1000 persons of the Bahutu and Batutsi tribes in 22 places in the territory of Ruanda. The state of the thyroid gland was classified as showing no enlargement, parenchymatous goitre (3 grades), or nodular goitre (2 grades). As there was no difference between the tribes, the results are presented together. The incidence of goitre was larger among women than men; it was highest among men just before the age of 20 and among women from 20 to 40. There were few nodular or large parenchymatous goitres, and no cretin, deaf mute or person with Graves' disease was seen. The weighted mean of incidence for both sexes ranged from 1.83 to 28.37 per cent. in different places. Geographically the association of goitre seemed to be with high rainfall and high content of K, Mg, and Ca in the water.—E. M. Hume.

2781

DE SMET, M. P. Contribution à l'étude de la pathologie thyroïdienne au Congo Belge. [Thyroid pathology in the Belgian Congo.] *Ann. Soc. belg. Méd. trop.*, 1954, **34**, 47-101. Flemish summary.

Goitre is endemic in the neighbourhood of Yangambi on the right bank of the Upper Congo, in the triangle formed with its tributary the Aruwimi. From Yangambi towards the north and the Aruwimi river, the incidence increases from about 1.5 to 80 per cent. of the population. On the left (south) bank of the Congo the population is reported to be free of the disorder. The explanation given is that centuries of rain have washed out iodine from the soil on the right bank, which is aeolian in type, but the alluvial soil on the left bank is being constantly reinforced with minerals from the river. Among dwellers on the actual river banks on either side, where much fish is consumed, there is no goitre.

In only about 3 per cent. of the goitrous people is the goitre of a pathological type. The greater

part of this long paper is devoted to a detailed description of 150 patients, mostly women, admitted to the Yangambi Hospital with toxic goitre, of the operative procedures adopted and the complications encountered, and of the results of the histological examination of the tissues removed. Biochemical tests included measurement of the degree of fixation of administered radio-active iodine in normal subjects, and in goitrous patients before and after operation. Of the 150 patients, 86 per cent. came from tribes on the right bank of the Congo and 14 per cent. from tribes on the left bank. The habits and customs of the two sets of tribes are said to differ very little. Six female patients with goitrous fibroma came from all districts and there was no association with endemic goitre; this condition, often accompanied by sterility, is considered to be associated with hypersecretion of folliculin.

In a special inquiry, 14 per cent. of 74 goitrous patients attending hospital provided evidence of heredity playing a part in the etiology.—H. Chick.

2782

VELGHE, A. De l'influence du goitre sur la stérilité en chefferie des Matapa. [Influence of goitre on sterility in a district of the Matapa.] *Ann. Soc. belg. Méd. trop.*, 1954, **34**, 127-134. [Fonds du Bien-être Indigène, Formation Médicale de Vieux, Kasongo.] Flemish summary.

In a study of sterility in women of the district, simple goitre was found to be more frequent than in the neighbouring districts. Measurements of basal metabolism were made on 132 women and 34 men, of whom 34 and 5, respectively, were goitrous. The relatively high values obtained in about 1/3 of the subjects, whether goitrous or not, is attributed to the difficulty of preventing emotional excitement during the test. Lack of iodine in the water and soil is not considered to be primarily responsible for the frequency of goitre, since it is much less in adjacent communities living in the same external conditions. It is considered that the sterility among the women is due to a conditioned deficiency of iodine produced by an excessive secretion of the sex hormone, folliculin, acting as a goitrogenic agent. The men are less affected by goitre, since the secretion of testosterone is generally normal in amount. The distribution of iodised salt as a prophylactic measure is recommended.—H. Chick.

2783

MORINAGA, H. Medical studies on the rural people. 2. A study on the incidence of struma in the south-western rural districts of Okayama Prefecture, Japan. *Rep. Balneol. Lab. Okayama Univ.*, 1954, No. 14, 56-61. [Div. Int.

N.A. and R., April 1955

Med., Balneol. Lab., Univ. Okayama.] In Japanese: English summary.

In 1950 a survey of 1480 schoolchildren aged from 6 to 14, in the vicinity of Yakage in Okayama Prefecture, and of 1516 outpatients in Yakage Hospital, showed a respective mean percentage incidence of struma of 4.6 and 4.7. The percentage [presumably in all subjects] was 7.8 in spring and 2.98 in summer, so that the effect of season should not be neglected. (From summary.)

CAPPELL, D. F., HUTCHISON, H. E., HENDRY, E. B. and CONWAY, H. A new carbohydrate-iron haematinic for intramuscular use. *Brit. Med. J.*, 1954, ii, 1255-1257. [Dept. Pathol., Univ. Glasgow.]

A new dextran-iron complex, Imferon, was effective and non-toxic in the treatment of 15 patients with Fe deficiency anaemia. Absorption by way of the lymphatics was demonstrated in one patient who died of cerebral embolism.

F. C. Aitken.

2788

SCOTT, J. M. and GOVAN, A. D. T. Anaemia of pregnancy treated with intramuscular iron. *Brit. Med. J.*, 1954, ii, 1257-1259. [Dept. Res., Glasgow Royal Maternity and Women's Hosp.]

Fifty patients with anaemia of pregnancy were treated with Imferon, intramuscularly. All responded satisfactorily. Comparison with a previous series treated with saccharated oxide of iron, intravenously, showed that utilisation of Fe for Hb formation was the same for the 2 preparations. Since Imferon contains 5 per cent. elemental Fe compared with 2 per cent. in saccharated oxide of iron, fewer injections of Imferon are required.

F. C. Aitken.

2789

BATRD, I. M. and PODMORE, D. A. Intramuscular iron therapy in iron-deficiency anaemia. *Lancet*, 1954, 267, 942-946. [Royal Infirmary, Sheffield.]

In a small group of anaemic and normal subjects serum Fe rose to a peak after intramuscular injection of a dextran-iron preparation and returned to about normal pre-injection level 6 or 7 days after injection. The time taken to reach the peak and its height were variable. There was no increase in urinary excretion of Fe. Of 40 anaemic patients treated with intramuscular injections of the dextran-iron preparation 38 responded adequately. Injections were well tolerated.—F. C. Aitken.

2790

HASEGAWA, M. and ITO, S. The importance of copper in the treatment of anaemia. *Keio J. Med.*, 1954, 3, 25-34. [Dept. Int. Med., Sch. Med., Univ. Keio.]

Of 360 anaemic patients examined during 2 years, 13 showed low serum values for Cu. Three cases are described in which anaemia that had proved intractable to other treatment was cured when copper sulphate in doses of 10 mg. daily was given in addition to Fe and folic acid. Both hyperchromic and hypochromic anaemia responded to treatment with Cu. It is recommended that the Cu content of the serum should be examined in all patients with anaemia who fail to respond to the usual treatment.—A. M. Copping.

2791

FORSHAW, J. W. B. Idiopathic hypochromic anaemia in males. *Brit. Med. J.*, 1954, ii, 908-910. [Whiston Hosp., Liverpool.]

Idiopathic hypochromic anaemia in males is rare. Eleven cases are reported, in none of which was there evidence of haemorrhage or steatorrhoea. The etiology is discussed. Poor Fe absorption and, in adolescence, poor Fe intake are thought to be the causes.—F. C. Aitken.

2792

DOMINICI, G., OLIVA, G. and TRAMONTANA, C.
Influence of the gastric juice on tissue metabolism. *Lancet*, 1954, 267, 1105-1106. [Med. Clin., Univ. Perugia, Italy.]

Gastric juice obtained from human subjects by stomach tube, centrifuged and brought to pH 7.5 was injected intramuscularly. Gastric juice from healthy subjects or from those with pernicious anaemia and histamine-resistant achlorhydria, hyperchromic hypersideraemic anaemia of pregnancy, hypoplastic anaemia of several types or granulocytopenic syndromes, when injected into healthy subjects, or those with idiopathic hypochromic anaemia, or with achlorhydria with or without pernicious anaemia, always caused a drop in blood sugar, serum Fe and serum amino-acids, the lowest values occurring 4 to 6 hr. after the injection. Gastric juice from a patient with hypochromic anaemia and achlorhydria did not produce these effects.

The etiology of idiopathic hypochromic anaemia and related syndromes is discussed in the light of these findings. Treatment with gastric juice from normal subjects was beneficial, and the syndromes are thought to be caused by a deficiency of the substance capable of causing the blood changes described above. An example is given of a woman with hypochromic anaemia, glossitis and histamine-resistant achlorhydria, cured by treatment with gastric juice.—D. Duncan.

2794

KÜNKEL, H. A., MAASS, H., SCHMERMUND, H. J. and GOLDECK, H. Tierexperimentelle und klinische Untersuchungen zur Schwangerschafts-Sideropenie mit einem Radio-Eisen⁵⁵ Komplex. [Animal experiments and clinical investigation of iron deficiency in pregnancy with a complex of radio-active ferric iron.] *Klin. Wochenschr.*, 1954, 32, 878-886. [2. Med. Klin., Univ. Hamburg, Eppendorf.]

Three rabbits, which had been made anaemic by removal of 100 to 140 ml. blood, and in which the Hb content of the blood had fallen to about 40 per cent. of the original, received a single intravenous injection of from 2.3 to 2.9 ml. Ferronascin, a preparation containing labelled ⁵⁵Fe and ⁵⁹Fe in amounts equivalent to from 25 to 32 mg. ferric iron. A continuous rise of radio-active Fe in the red blood cells occurred during the following 8 to 15 days and when the rabbits were killed deposits of the labelled Fe were found chiefly in

the liver, spleen, bone marrow and adrenal glands. The red blood cells of 3 normal rabbits, similarly treated, showed a much smaller rise in radio-active Fe. In both groups there was an immediate rise of radio-active Fe in the plasma followed by a fall within 12 hr. after the injection.

Tests were made on 8 pregnant women in whom Fe deficiency had been indicated by a marked rise of serum Fe after administration of a ferrous iron compound. They received intravenous injections of Ferronascin equivalent to 30 mg. radio-active Fe. Little radio-active Fe was detected in the red blood cells in the ensuing 24 hr., but later an increase occurred for the next 2 months in varying degree in the different subjects; the average total was estimated to represent about 75 per cent. of the dose injected. The test was controlled by trials with 2 non-pregnant women with severe hypochromic anaemia and 2 with normal Fe metabolism; after Ferronascin injections they showed absorption in their red blood cells of about 90 and 40 per cent., respectively, of the radio-active Fe injected. In all subjects there was a rise in the first 2 to 5 days of labelled Fe in the plasma, most of which was combined with protein; subsequently only traces were found in the plasma. In the umbilical blood of the infants born from 13 to 109 days after the injection of the mother an amount of radio-active Fe was found equal to about 7 per cent. of that in the maternal blood. No significant transmission of Fe to the milk was detected.—H. Chick.

JHATAKIA, K. U. and DAMANY, S. J. **A few observations on the nature and aetiology of anaemias.** *J. Indian Med. Assoc.*, 1954, 24, 129-132. [Sir J. J. Hosp., Bombay.]

The subjects were 100 hospital patients, 62 male and 38 female, between 10 and 72 years of age. Their complaints and the clinical findings are tabulated and described. The main haematological findings were: in 50 patients the red cell count was less than 2 million per c. mm. blood; Hb, by Sahli method, was below 6 g. per 100 ml. in 63 patients; mean corpuscular volume outside

the range 80 to 95 c.p. showed 35 as microcytic and 60 as macrocytic; mean corpuscular Hb was below 27 μg . for 59 and above 32 μg . for 5; mean corpuscular Hb concentration was below 32 per cent. in 92. Bone marrow also was examined in 89 patients; in only 1 was it megaloblastic, in all the others normoblastic (46 normoplastic, 28 hypoplastic and 14 hyperplastic).

Of the 60 patients with macrocytic anaemia 1 had megaloblastic marrow; the other 59 had normoblastic marrow (31 normoplastic, 23 hypoplastic and 5 hyperplastic). The existence of macrocytic anaemia with non-megaloblastic bone marrow may, it is suggested, be associated with a low level of blood plasma proteins.—D. Harvey.

2798

YOUSSEF, A. F., ALI, A. M. and EL MAHDI, A. A. H. **Anaemia in pregnancy in Egypt. A problem of national importance.** *J. Egypt. Med. Assoc.*, 1954, **37**, 319-332. [Dept. Obstet. Gynaecol., Kasr-el-Aini Hosp., Cairo.]

In 50 unselected pregnant women, aged from 17 to 42 years, attending the antenatal service at the Kasr-el-Aini Hospital, the blood of 3 was normal, and that of 19 showed what is described as physiological anaemia, reduction of the red cell count and of Hb concentration due to increase in the plasma volume. Of the remainder, 12 showed hypochromic anaemia with Hb concentration less than 10 g. per cent. and a colour index below 0.9; 2 had a macrocytic orthochromic type with red cell count less than 3.5×10^6 per c.mm., Hb less than 10 g. per cent. and a colour index above 0.9; in 14 the 2 types of anaemia were mixed. In 25 of the subjects there was a significantly low gastric acidity; the 25 included 13 of the 16 women who showed the macrocytic and mixed types of anaemia. Parasitic infection was present in only 2 instances. The high incidence of anaemia in pregnant women is attributed to faulty nutrition, and especially to defective absorption of iron and deficiency of animal protein in the diet.—H. Chick.

2799

MOHI-ELDIN, O. **Studies in anaemias of pregnancy.** *J. Egypt. Med. Assoc.*, 1954, **37**, 613-628.

The study was made on 200 supposedly normal pregnant women, mostly resident in Cairo, attending an antenatal outpatient clinic; 20 non-pregnant women of the same age and social class served as controls. All the subjects were free from parasites. In the blood of the non-pregnant group the average Hb value was 12.4 g. per 100 ml., 86 per cent. of normal, and the red cell count 4.7×10^6 per c.mm. Dilution due to the increase of plasma volume which is usual in pregnancy would, at its maximum, reduce the Hb value to

10.1 g. and the red cell count to 4.01×10^6 . Among the pregnant subjects 44 had a Hb value ranging from 10 to 12.4 g., mean corpuscular volume 83.7 c.p. and mean corpuscular Hb 26.9 μg ., figures very near to those of 85 and 27.4, respectively, for the non-pregnant group. This group of pregnant subjects is considered to be normal and to show only "physiological anaemia". There was little response to administration of Fe.

Of 124 pregnant women with blood Hb below 10.1 g. per 100 ml., 100 showed typical hypochromic microcytic anaemia, with average values for Hb 8.4 g., red cell count 3.9×10^6 per c.mm., mean corpuscular volume 76.3 c.p., mean corpuscular Hb 22.4 μg . and colour index 0.69. When 17 of this group were treated for 6 weeks with Fe given as 1.8 g. daily of ferrous gluconate, there was great improvement in 15, with a daily increase of about 0.9 g. per cent. Hb in the blood, and of 37,000 per c.mm. in the red cell count. The 2 women who did not react to Fe did so when HCl was given between meals.

There were only 4 women with typical macrocytic anaemia, showing a mean corpuscular volume above 92 c.p., a red cell count of 2.8×10^6 per c.mm., and a colour index of 1.09. A mixed type of anaemia was shown by 28 patients, some of whom gave little response to Fe, but improved immediately when receiving in addition a high-protein diet in hospital. The blood of the women with macrocytic anaemia also was restored to normal when they were given a high-protein diet with 110 g. protein daily, including meat, milk and eggs.

A study of the usual diet of these women showed that it consisted mainly of rice, lentils, beans, potatoes and other vegetables and cheap fruits and that it was deficient in both Fe and protein, of which the daily intakes were estimated to be about 6 mg. and 37 g., respectively, mostly from vegetable sources.—H. Chick.

LOTTNER, B. **Über einen Behandlungsversuch mit Haferflocken bei minderbegabten Kindern. [Experimental treatment of mentally subnormal children with oat flakes.]** *Deutsch. med. Wochenschr.*, 1954, **79**, 1837-1840. [Abt. Jugendpsychiat., Gesundheitsamt, Düsseldorf.]

For 2½ months 25 boys and 8 girls aged between about 9 and 12 years and with intelligence quotients mostly between 70 and 90, from poor families and attending 2 classes in a special school for the backward, enjoyed a breakfast of oat flakes in the form of "Müslí", i.e., uncooked, stirred up with a little milk and sugar and eaten with fruit and nuts. The oat flakes supplied, per 100 g., 410 Cal., protein 11.5, fat 9.8, carbohydrate 66.3 g., vitamin B, 500 µg., vitamin E 60 mg., Ca salts 1.5 g., Fe 31 mg., Cu 0.5 mg., F 3 µg., Mn 4.87 mg., Zn 7.0 mg., I 4 µg. Many of the children improved in arithmetic, dictation, letter-cancelling and drawing-completion tests, and teachers and parents agreed that they were less restless and less easily tired and showed better concentration. It is suggested that the beneficial effects of oat flakes may be due to their high protein content.

FLETCHER, A. P. The effect of weight reduction upon the blood-pressure of obese hypertensive women. *Quart. J. Med.*, 1954, 23, 331-345. [Wright-Fleming Inst. Microbiol., London.]

The blood pressure of obese middle-aged or elderly women outpatients, 155 in all, under treatment for at least 4 months with a diet supplying from 600 to 1000 Cal. daily, was measured monthly by sphygmomanometer. The women were classified in 4 groups (blood pressure normal or high at the outset, success or failure in losing at least 14 lb. weight). Statistical analysis of the results showed that in hypertensive women who lost weight the fall of blood pressure, both systolic and diastolic, was highly significant compared with that of hypertensive women who did not lose weight; and this was still true when a correction was made for error due to the decrease

of arm girth as weight was lost. A follow-up, admittedly incomplete, suggested that the effect was lasting. It was concluded that in this group of women obesity had played some part in raising the blood pressure.—W. M. Deans.

DOLE, V. P., SCHWARTZ, I. L., THAYSEN, J. H., THORN, N. A. and SILVER, L. Treatment of obesity with a low protein calorically unrestricted diet. *Amer. J. Clin. Nutr.*, 1954, 2, 381-391. [Hosp., Rockefeller Inst. Med. Res.] Spanish summary.

The therapeutic diet supplied 35 ± 5 g. protein daily; non-protein calories were unrestricted. Thirty-six patients were given this diet for several weeks, 16 of them after a control period of 3 to 6 weeks during which a supplement of 46 to 96 g. protein had been given daily. Six subjects were given the diet supplemented at the lower rate and lost weight so rapidly that they were continued on that intake of protein throughout the experiment. Four of the 16 patients also lost weight during the period on the supplemented diet. On the basal diet weight loss was more rapid. Patients consumed less of unrestricted non-protein calories on the low-protein diet. A follow-up study 3 to 12 months later showed that 52 per cent. of the patients had regained all of their original weight, 30 per cent. showed little change in weight and 18 per cent. had continued to reduce without supervision.—F. C. Aitken.

BECK, J. C. and BRÖCHNER-MORTENSEN, K. Observations on the prognosis in anorexia nervosa. *Acta med. scand.*, 1954, 149, 409-430. [Med. Dept. A, Univ. Hosp., Copenhagen.]

A clinical study was made of 28 women with anorexia nervosa, of whom 25 were followed up for an average of 11.8 years. The clinical response during the initial time in hospital was good in 23, moderate in 1 and poor in 4. Of the 25 followed up, 20 were in excellent health, 4 had persistent signs and symptoms and showed chronic inanition, and 1 had died as a consequence of the disorder.

It is concluded that prognosis is better than has previously been inferred, only the more severe personality disorders having an unfavourable prognosis; this accounts for the poor prospects suggested by results from psychiatric departments, which receive selected patients.—D. Duncan.

VAN BOUWDIJK BASTIAANSE, M. A. **Etiological aspects in the problem of toxemia of pregnancy.** *Amer. J. Obstet. Gynecol.*, 1954, **68**, 151-158. [Dept. Obstet. Gynaecol., Univ. Amsterdam.]

This review first discusses the diagnostic criteria, which the author concludes are hypertension and pitting oedema, with or without albuminuria. In etiology, the essential feature is thought to be increased resistance in the blood vessels of the pregnant uterus, leading to a decrease in the flow of blood to the placenta. The relatively ischaemic placenta produces substances which cause albuminuria and retention of salt and water and also changes in the elimination of mineralocorticoids and pregnanediol. The general pathology of toxemia is the result of arteriolar spasm. Data are given illustrating the fall in the incidence of eclampsia in Dutch patients during the 1939-45 war; possible explanations were "the poor state of the muscular system caused by malnutrition. The poor condition of the muscles of the arterioles causes a fall in blood pressure. The diminished tonus of the uterine muscle results in a reduced pressure upon the vessels of the uterus so that more blood can pass through." As the incidence of eclampsia diminished, atonic post-partum haemorrhages became increasingly frequent. Treatment resolves itself into a question of how to increase the uterine circulation.

DAHL, L. K. and LOVE, R. A. **Evidence for relationship between sodium (chloride) intake and human essential hypertension.** *Arch. Int. Med.*, 1954, **94**, 525-531. [Dept. Med., Brookhaven Nat. Lab., Upton, N.Y.]

The results presented in the paper relate to 547 adults but in an addendum the observations are extended to include 897 persons. Of these, 397 added salt to food as a routine without previous tasting, 402 sometimes added salt after tasting

food and 98 never used salt at table. In these 3 groups the numbers of persons with hypertension were 40, 30 and 1.

While it is admitted that high NaCl intake may be merely a manifestation of the disease, a cause-effect relationship is postulated between NaCl intake and the development of hypertension and it is thought that only the Na ion is of importance.

6. FEEDING OF ANIMALS

GENERAL, INCLUDING DIGESTIBILITY TRIALS

2816

NEHRING, K. Zum Problem der Schaffung einer europäischen Futterwertseinheit. [The problem of procuring a European unit of feeding value.] *Arch. Tierernährung*, 1954, 4, No. 4, Beihefte, 19-37. [Oskar Kellner Inst. Tierernährung, Leipzig-Rostock.]

Units of feeding value have reference only to energy value for maintenance or production, and they have meaning only when balanced rations are used in experiments to measure the value of individual feeds or to estimate requirements of animals. The history and nature of feed units is reviewed from the hay unit of Thaer, via the Scandinavian barley unit to the Soviet oat unit (1 kg. oats = 150 g. fat in ruminants, which is equivalent to 1414 Cal.); and from Kellner's starch unit, via Møllgaard's NK₇ to Fuchs's Kellner unit, KE (see Abst. 2791, Vol. 21). In the interests of uniformity of application, it is suggested that Fuchs's idea be taken a step further, that the KE be taken as 2500 Cal., so removing it from the cattle context of 1 kg. starch and 2360 Cal. of ox fat, and that both "feed value" and requirement be expressed in terms of KE, i.e., multiples of 2500 Cal. Ideally both feed value and requirement should be in terms of net energy. Where there is no information in terms of net energy, or to procure sufficient calorimeter data to give a reliable result would be too expensive, the second best is digestible energy, and it too should be expressed in KE, i.e., units of 2500 Cal.

I. Leitch.

2817

BARBORIAK, J. Der Einfluss von Rohfaserzulagen auf den Energiehaushalt des Kaninchens. Ein Beitrag zur Erweiterung der Wertigkeitslehre von O. Kellner. [Effect of additions of fibre on the energy metabolism of the rabbit. Extension of the "value" system of Kellner.] *Thesis, Univ. Zürich*, 1953, pp. 74.

The "value" system by which Kellner evaluated feedingstuffs was based on experiments on oxen, in which he found that the productive effect of pure isolated nutrients was greater than that of the same nutrients contained in feedingstuffs such as hay and straw. He ascribed the decrease in value of the feeds to their fibre content, which increased the work of mastication and digestion, and possibly intensified fermentation processes. In the present work the effect on the energy metabolism of rabbits of fibre additions to a basal ration slightly above maintenance level was investigated. Finely ground winter-wheat straw

was added in amounts which increased the consumption of dry matter by from 110 to 177 per cent., of fibre by 216 to 972 per cent. and of ballast, i.e., indigestible organic matter, by 209 to 609 per cent. The added straw was found to be almost undigested, but the digestibility of the basal ration was not affected by the additions, except for a slight reduction of protein digestibility. With increasing amounts of fibre and ballast in the ration, the faecal excretion of N increased, but urinary N and N retention were not influenced. The energy metabolism, as represented by the energy of the digested feed, metabolisable energy, thermal and net energy, showed no regular effect of the fibre additions.

It is suggested that the differences between these results and those of Kellner may be due to anatomical and physiological differences in the digestive processes of ruminants and rabbits; to differences in the thermal compensation; to differences in activity of the experimental animals; or to partial digestibility of the wheat straw used by Kellner. Feeds high in fibre do not always show the loss of fat-producing power to be expected according to Kellner's "value" theory. It is suggested that there is need for further experiments on different species of animals, to find the true causes of the decrease in value of the digestible constituents in the different feedingstuffs.

BALCH, D. A., BALCH, C. C. and ROWLAND, S. J. The influence of the method of determination of lignin on the lignin-ratio technique for digestibility in the cow. *J. Sci. Food Agric.*, 1954, 5, 584-588. [Nat. Inst. Res. Dairying (Univ. Reading), Shinfield.]

Three methods of estimating lignin were compared: (1) Norman and Jenkins (Abst. 3136, Vol. 4) as modified by Gray (Abst. 4613, Vol. 17), (2) Ellis *et al.* (Abst. 2495, Vol. 16), (3) Armitage *et al.* (Abst. 2713, Vol. 18). The crude lignin values were corrected for their content of contaminating protein ($N \times 6.25$) and values for "corrected" lignin are quoted. Estimations on feed and faeces showed that method 1 gave the highest values, method 3 the lowest. The methods giving the higher lignin values gave lignins with a higher N content. The "corrected" values for 1 and 2

N.A. and R., April 1955

were similar, but method 3 gave consistently lower values.

From digestibility trials with 4 lactating cows over a 14-day period lignin digestibility coefficients were estimated. Method 1 gave mean values of 9.3 and 8.3 for crude and corrected lignin digestibility coefficients. For methods 2 and 3 the respective values were 4.7, 9.1 and 1.3, 4.4.

The method of Armitage *et al.* is recommended for use in the lignin-ratio technique.—D. M. Walker.

FOREMAN, C. F. and HERMAN, H. A. Effects of carbohydrate feeding levels on roughage digestion in dairy cattle. *Missouri Agric. Exp. Stat. Res. Bull.* No. 535, October 1953, pp. 56. [Columbia, Mo.]

The coefficients of digestibility of the nutrients of rations supplemented with varying amounts of molasses were estimated in a series of 5 digestion trials with Jersey, Guernsey, and Holstein cows. Rumen samples were taken at the end of each trial and the numbers of bacteria and protozoa with different levels of molasses were found. Coefficients of digestibility were estimated by the chromic oxide indicator method.

Five different hays were tested: a green lespedeza timothy hay of good quality, a stemmy alfalfa hay, a good alfalfa brome-grass hay, a medium alfalfa hay and a brown alfalfa hay of average quality. Hay was used alone or with a

grain mixture with molasses at levels of 1, 2, 4, 6 or 8 lb. daily. The digestibility of crude protein, cellulose and crude fibre of all hays increased when molasses was given at a rate of up to 2 lb. daily. The digestibility of N-free extractives increased as the level of molasses rose. When the roughage was good quality alfalfa brome hay, 4 lb. molasses daily greatly decreased the digestibility of crude protein, crude fibre and cellulose. It was concluded that up to 4 lb. molasses could be included in practical rations for dairy cows without detriment, except when the roughage was good quality alfalfa hay, when the limit of molasses feeding should be 2 lb. daily. A fall in the price of molasses might mean that up to 8 lb. could be given daily even though the digestibility of the roughage portion of the ration was reduced.

There was no relation between the type of ration and the numbers of protozoa in the rumen samples. Bacterial numbers increased as the level of molasses rose. A review is given of the literature on molasses as a source of carbohydrates and the effect of carbohydrates on digestibility.

RAYMOND, W. F., HARRIS, C. E. and KEMP, C. D. Studies in the digestibility of herbage. 5. The variation, with age, of the ability of sheep to digest herbage, with observations on the effect of season on digestive ability. *J. Brit. Grassland Soc.*, 1954, 9, 209-220. [Grassland Res. Inst., Hurley, Berks.]

Nine experiments were made with sheep ranging in age from lambs to 4-year-old on herbage feeds with digestibilities ranging from 60 to 80 per cent. In experiments 1 to 7 comparisons were made between animals of different ages fed at the same time on one particular feed (frozen herbage). In experiments 8 and 9 the same animals received this same feed at intervals as they became older.

There was an apparent increase in digestive capacity with age, but this increase did not occur with all feeds tested. Part of the variation may have been due to the level of feeding, an allowance being made by feeding each age-group at a dry-matter intake proportional to the average maintenance requirement of the sheep in the group. Experiments 8 and 9 indicated a seasonal fluctuation of digestibility, a fall in winter followed by a rise in summer.—D. M. Walker.

2826

SKAARE, S. Kjemisk innhold, fordøyelighet og forverdi i lusernehøy. [Chemical composition, digestibility and feeding value of alfalfa hay.] *Forsk. Forsøk Landbruken*, 1954, 5, 375-391. [Stamsaeds-gard Vidarshov, Hjelsum.] English summary.

Results of 11 years' study of the composition of alfalfa hay in Norway are summarised. The first 6 years' results were reported earlier (Skaare, *Forsk. Forsøk Landbruket*, 1950). The stands examined were mixed, of alfalfa, red clover and timothy, with alfalfa dominant.

Details are given of botanical composition and of digestibility by wethers of 2 cuts in each of 9 years, taken over the years from 6 different centres, and of the composition of 33 samples from mixed pastures, 20 to 41 per cent. alfalfa, 1 to 4 years old, taken over 11 years. For the samples of which the digestibility was estimated, first cut had a feeding value of 1.91 kg. per feed unit, 220 g. digestible crude protein per feed unit and 17.0 g. Ca and 2.32 g. P per kg., all computed to 85 per cent. dry matter in hay. Corresponding values for second cut were 2.19 kg., 202 g., 16.3 and 1.99 g. For the other samples, with average digestibilities applied, the same values were 2.34 kg., 151 g., 8.92 and 1.78 g.—I. Leitch.

2827

TILLMAN, A. D., SIRNY, R. J. and MACVICAR, R. The effect of alfalfa ash upon the digestibility and utilization of cottonseed hulls by sheep. *J. Animal Sci.*, 1954, 13, 726-731. [Dept. Animal Husb., Oklahoma Agric. Exp. Stat.]

Three digestibility trials with 14 Western wether lambs in all are described. Addition of alfalfa ash to a semi-purified basal ration of which 60 per cent. was cottonseed hulls improved the digestibility of dry matter, crude fibre, ether extract, N-free extract, organic matter and energy ($p = 0.01$) and of the crude protein ($p = 0.05$). Sheep on the basal ration lost weight, but they gained weight when the alfalfa ash was added to the ration. Depletion-repletion studies showed that cobalt had no effect, but that synthetic alfalfa ash caused a gain similar to that of natural alfalfa ash.

THOMAS, B. and SMITH, A. N. The nutritive value of *Calluna vulgaris*. 3. Digestibility at four and ten years after burning. *J. Agric. Sci.*, 1954, 45, 104-109. [King's Coll. (Newcastle upon Tyne), Univ. Durham.]

For earlier work see Abst. 5149, Vol. 23.

Two Blackface wethers were used for digestibility trials with heather collected from moorland 4 years and 10 years after burning. Digestibility values were obtained on diets containing equal proportions of hay and heather (periods 2 and 3). Hay alone was given in the first and fourth periods of the experiment.

Metabolic faecal N was estimated by the Wedemeyer method, crude protein on fresh faeces, and other proximate nutrients on the dry matter.

Ether extract, crude protein and N-free extract had a higher digestibility in young heather than in old heather, but the reverse was apparently true for the digestibility of crude fibre. Metabolic faecal N excretion was reduced by the addition of heather to the diet.—D. M. Walker.

KOVAL'SKII, V. V. Znachenie mikroelementov v zhivotnovodstve. [The importance of microelements in stock raising.] *Priroda*, 1954, No. 4, 11-20.

This is a general discussion of the importance of trace elements in animal husbandry, with brief references to particular diseases occurring in different areas where there is a deficiency of one of the trace elements, with special emphasis on cobalt.

In the U.S.S.R. the largest zone is that of turf-podsol soils deficient in cobalt, copper and iodine. In certain regions where the soils are deficient in Co, the sheep, particularly the lambs, suffer from epizootic anaemia. By using Co salts as a supplement for sheep in Co-deficient regions, it was found possible to increase the weight of lambs at birth by 24 per cent. As leguminous plants are particularly rich in Co it was found that where perennial legumes were being grown animals were less liable to disease.

In "biogeochemical" areas where soils and fodder are deficient in Cu animals suffer from enzootic ataxia and plants from spot disease. As an example of areas characterised by excess of micro-elements molybdenum areas are quoted, where cattle suffer from enzootic diarrhoea, selenium areas where the animals develop so-called alkali disease, beryllium and strontium areas where the animals are attacked by particular forms of rickets, and fluorine areas where animals suffer from fluorosis of the bones and spotted enamel of the teeth. In Northern Kazakhstan, where the soils and fodder are rich in nickel, animals often become blind owing to deposit of nickel forming on the cornea.—H. Scherbatoft.

FÉVRIER, R., JACQUOT, R., MATET, J. and PERO, R. Influence du mode de préparation sur la valeur nutritive de trois farines de poisson. Le problème des eaux de presse et de la protéolyse. [Effect of method of preparation on the nutritive value of three fishmeals. The problem of press water and proteolysis.] *Ann. Zootech.*, 1954, 3, 223-246. [Stat. Recherches Élevage, Jouy-en-Josas.]

A quantity of sardines was divided into 3 parts from which the following meals were prepared:

Vol. 25, No. 2

E (extracted), with press water removed and the remainder oven-dried; I (incorporated), with press water dried and re-incorporated into meal prepared like E; and D (degraded), for which the fish was broken down enzymically and then dried. The meals were sent to 3 laboratories where they were compared in trials with rats, pigs and chickens.

For experiments with rats of 55 to 60 g. weight in groups of 6, the 3 meals were given at the 5, 10 and 15 per cent. levels, for about 6 weeks, during which time 4-day balance trials were made on each group. Growth was good only in the groups receiving 15 per cent. fishmeal. Meal E was slightly better than D or I, especially at the high level. For protein efficiency D followed closely, but this meal produced digestive disturbances and was somewhat unpalatable.

For 3 groups of 9 young pigs the 3 meals were incorporated at 5.5 to 6.5 per cent. to give a crude protein content of 135 g. per kg. diet, the rest of the diet consisting of maize and groundnut meal. The pigs were fed to appetite for 10 weeks, and then only 2 of each group continued to receive fishmeal until they were killed at 100 kg. liveweight. There was no significant difference between the 3 meals under these conditions.

The 3 meals were given as the sole source of animal protein to groups of 10 chickens, I and D at 5 per cent. and E at 6 per cent. of the ration, which provided 19.4 to 19.8 per cent. crude protein. None gave as good results as a control ration without fishmeal, but there was no difference between the 3 fishmeals.—D. Duncan.

2839

SCHREUBEN, L. W. and CLIFTON, R. E. Grain substitution in feeding livestock. *Kansas Agric. Exp. Stat. Circular* No. 299, July 1953. [Manhattan, Kans.]

Scales are given from which may be read off the comparative monetary values of maize, wheat, barley, sorghum and oats for the feeding of dairy cows and the fattening of beef cattle, pigs and lambs in Kansas. These scales take into account the nutritional values of the different grains for different classes of stock. The object is to provide the farmer with a rapid means of assessing the most economical feed to use, with reference to the grain market.—I. A. M. Lucas.

VEZZANI, V. and CARENA, A. L'uso alimentare dei gusci di cacao. Sintesi delle esperienze condotte dall'Istituto Zootecnico e Caseario per il Piemonte. [The use of cacao pods in feeding. Summary of experiments at the Istituto Zootecnico e Caseario of Piedmont.] *Riv. Zootech.*, 1954, 27, 282-285.

Cacao pods may be used for feeding cattle, sheep or pigs. Pigs, especially when young, are somewhat more sensitive than the other species to the alkaloids, theobromine and caffeine, and showed some loss of appetite when given pods at rates between 3 and 5 per cent. soon after weaning. The pods could be substituted for bran in rations for cattle and sheep, and were less than two-thirds the price of bran.—D. Duncan.

PRESTHEGGE, K. Forsøk med lav til drøvtyggere og svin. [Experiments with lichen for ruminants and pigs.] *Forsk. Forsøk Landbruget*, 1954, 5, 437-523. [Norges Landbruks-høgskole, Aas.] English summary.

Lichen has always been used as winter feed in Norway and is regarded as much better than straw. In the districts where the supply is plentiful, large quantities (up to a hundred loads) may be collected. In some areas the lichen moors are used as reindeer pastures, but that is possible only in treeless areas. Most of the lichen moors are in pine or birch forest or on the tree-line.

The lichens commonly collected are *Cladonia rangiferina*, *Cl. alpestris* and *Cl. sylvatica*, all called "reindeer moss"; *Cl. alpestris* is the most plentiful. The biggest lichen moors are in Finnmark and when they are heavily grazed by reindeer, smaller, more rapidly-growing lichens such as *Stereocaulon paschale* and *Cetraria nivalis* appear. *Cetraria islandica* (Iceland moss) and other *Cetr.* species are used also.

Older chemical studies found *Cetraria* rich and *Cladonia* poor in water-soluble carbohydrates. Conventional feedingstuff analysis gives fibre content as 40 per cent. of dry matter for *Cladonia* and only 10 per cent. for *Cetraria*.

The chief carbohydrate in *Cetraria* is lichenin, and chemical studies of it are reviewed. In chemical composition it resembles cellulose, in physical properties it is nearer to starch. Ether extract varies in quantity and kind from one species to another; there is little fat and not enough total ether extract to make investigation possible of the "lichen acids" which make up most of it.

Older biological studies of lichen show that higher animals cannot digest even the highly water-soluble lichenin, since they produce no lichenase; lower animals and bacteria do. *Cetraria* has been used in bread in time of food shortage and tests made during the recent war are reviewed. *Cetraria cucullata* contains enough vitamin C to prevent and cure scurvy (Granat, Abst. 4970, Vol. 6). Earlier experiments with farm stock are also reviewed.

In the present series of studies analyses were made of 30 samples of *Cladonia alpestris*, 50 of

Cetraria islandica and 4 of *Centr. nivalis*, 2 of *Stereocaulon paschale* and 1 each of *Cladonia rangiferina* and *sylvatica*, *Alectoria ochrolia* and *Cetr. crispa*. The chemical composition may be summarised as follows in per cent. of dry matter: organic matter 98.0 to 99.4; crude protein 2.15 to 7.1 (*Stereocaulon* only; others maximum 4.1); crude fat 0.7 to 8.5; N-free extract, *Cladonia* and *Stereocaulon* 53.0 to 66.8, others 82.6 to 85.6; fibre, *Cladonia* 24.2 to 41.2, others 2.6 to 10.05.

Digestibility trials with sheep were made, 36 with *Cladonia alpestris*, 2 with *Cetraria islandica* and 5 with *Cetraria nivalis* of which 2 were after treatment with alkali. The basal ration was of 600 g. hay, cereal, herringmeal and salt (NaCl).

The mean digestibility coefficients in that order were for organic matter 47.8, 48.3, 73.9 and 61.1; for N-free extract plus fibre 52.1, 54.2, 78.9 and 65.3. Digestible protein was negative, -3.5, -3.9, -3.2 and -2.3 per g. dry matter.

The experiments with *Cladonia* were repeated in several years in an attempt to discover reasons for the considerable variations in digestibility, but no relation was found to any of the following: length of preliminary accustoming period, whether the sheep came from a lichen district or not, whether the lichen was stored fresh and frozen, or dry, whether it was given dry or steeped, or the quality of the hay in the basal ration. There was a negative correlation ($r = -0.48$) between fibre content and digestibility of organic matter. The highest digestibility was found with *Cetraria nivalis* but, in its natural condition, it was not readily eaten and caused digestive disturbances. After alkali treatment it was eagerly taken but part of the digestible matter was lost.

The feeding value of the more important species, computed by the methods of Kellner and Møllgaard or of Hansson, corrected by Lehmann's "ballast reduction" for fibre, was in feed units per 100 kg. dry matter: *Cladonia alpestris* 31 or 36, *Cetraria islandica* 64 or 71 and *Cetraria nivalis*, alkali-treated and washed, 54 and 60.

A feeding experiment with 2 groups each of 7 cows is described in detail. Lichen, chiefly *Cladonia alpestris*, 10.75 kg., replaced 2.05 kg. cellulose, i.e., in approximately equivalent feed unit value. Milk yield was slightly increased and percentage fat reduced. In terms of 4 per cent. milk, there was no significant change in milk and there was none in bodyweight. Two groups, each of 11 pregnant ewes, were similarly fed, with lichen replacing cellulose, and again the records of performance were not significantly different.

From the experiments with cows and ewes the feeding value of mixed lichens, chiefly *Cladonia alpestris*, is reckoned to be 0.45 feed unit per kg. dry matter.

The experiments with pigs were with *Cetraria islandica* boiled for $\frac{1}{2}$ hr. (without effect on digestibility) or for 2 hr. in water; and with *Cladonia alpestris*, soaked in 0.5 per cent. NaOH or boiled in dilute HCl or H_2SO_4 . Boiling for 2 hr. increased the digestibility of organic matter of *Cetraria* from 27 to 45 per cent.; that of *Cladonia* after alkali treatment was 45 and after acid hydrolysis 65 per cent. Loss of protein was up to 100 g. per kg. dry matter of lichen. In feeding experiments there were 2 groups each given a normal cereal and herringmeal ration to 60 per cent. of their normal allowance and one given one or other of the prepared lichens. None of them had any feeding value for pigs.

The gathering and storage of lichen is described and discussed. It is a useful fodder for ruminants. I. Leitch.

JOUBERT, D. M. and HAMMOND, J. Maternal effect on birth weight in South Devon \times Dexter cattle crosses. *Nature*, 1954, 174, 647-648. [Sch. Agric., Univ. Cambridge.]

Three South Devon heifers were inseminated with Dexter semen and 3 Dexter females similarly with South Devon semen. After conception all animals received routine treatment. The average birthweight of calves from the South Devon dams was 72 lb. They were thus 22 lb. below the average for pure South Devon calves and 20 lb. above the average for pure Dexter calves. The calves of the Dexter dams had an average birthweight of 57.5 lb., only slightly heavier than the average for pure Dexter calves. It was concluded that these results provide evidence of a maternal effect on birthweight.

GRIMBERGEN, A. H. M. Enige proeven in vitro en in vivo met "Rumex" een droogproduct, bereid uit pensinhoud. [Tests *in vitro* and

Vol. 25, No. 2

in vivo with Rumex, a dried product, prepared from rumen contents.] *Inst. Moderne Veevoeding "De Schothorst"*, S42, pp. 8. English summary.

Reports of improved growth of calves given rumen contents from older cattle are reviewed. Trials at "De Schothorst" have not shown any benefit, and possibly benefit would be expected only for calves isolated from birth from older animals.

Trials are described with a proprietary preparation, Rumex. Incubated with fresh or sterilised rumen contents in suitable culture medium it had no effect on digestion of filter paper; cultured on bouillon agar with 0.1 per cent. glucose it contained a viable streptococcus with the characteristics of *Str. bovis*.

In tests with calves, 4 were reared in contact with older cattle, 2 given Rumex in the prescribed amounts daily and 2 without, and 3 were reared in isolation from cattle but not from other animals, 2 with Rumex. There was no difference in rate of growth or condition between ordinary and isolated with or without Rumex.

GORDON, C. H., MOORE, L. A. and HOSTERMAN, W. H. The feeding value of U.S. No. 1 Alfalfa Hay and U.S. No. 2 Alfalfa Heavy Timothy Mixed Hay. *J. Dairy Sci.*, 1954, 37, 1116-1122. [Dairy Husb. Res. Branch, Agric. Res. Serv.]

Six lots of hay were given as the sole ration to 6 groups of 4 heifers for 120 days. Analysis showed 3 hays to have an average grade of U.S. No. 1 Alfalfa Hay and 3 an average grade of U.S. No. 2 Alfalfa Heavy Timothy Mixed Hay. Heifers fed on the former ate 24 per cent. more dry matter and gained 91 per cent. more bodyweight than those fed on the latter. In order of decreasing daily weight gains the alfalfa leaf content, protein and palatability as measured by dry matter consumption also decreased in the respective hays, while timothy and crude fibre increased. The addition of alfalfa ash or soya bean protein for 30 days after the feeding trial had no significant effect on growth rate.—A. Hepburn.

2867

ITTNER, N. R., BOND, T. E. and KELLY, C. F. Increasing summer gains of livestock with cool water, concentrate roughage, wire corrals, and adequate shades. *J. Animal Sci.*, 1954, 13, 867-877. [Div. Animal Husb., Univ. California, El Centro.]

During 2 experiments when the mean air temperatures were 91.8° and 91.3° F., respectively, with mean relative humidities of 40 and 36 per cent., Hereford steers were kept in 50 × 60 ft. corral pens enclosed by fences constructed of four 2 × 10 in. planks. Each pen had a hay or aluminum shade 10 ft. above ground.

In 1952, 3 groups each of 10 bullocks of average liveweight 768 lb. were given during a 71-day test period either uncooled drinking water at 89.6° F., or cold water at 65° F., or cold water plus a shower from sprays covering two-thirds of the corral. They were fed to appetite twice daily. These groups gained 0.78, 1.04 and 0.94 lb. daily, respectively, but the differences were not statistically significant. It is suggested that the shade area of 41 sq. ft. per steer was probably insufficient and

that the high humidity caused by spraying caused the slow growth in group 3 as compared with group 2.

In 1953, 4 groups each of 7 bullocks of average liveweight 871 lb. were given during an 84-day test period either hay feed plus cold drinking water, at 65° F., or hay and grain feed plus cold drinking water, or hay and grain feed plus uncooled drinking water at 89.2° F., or hay feed plus uncooled water. These groups gained 1.51, 2.01, 1.57 and 1.18 lb. daily, respectively. The effect of hay feed as compared with hay and grain was statistically significant and was attributed to the higher heat increment of the hay diet. The effect of uncooled water as compared with cold water was also statistically significant. There was no significant feed × water interaction. In both experiments the animals given cold water drank less than those given uncooled water.

Growth was better in corrals enclosed by wire fences than in those enclosed by heavy wooden fences. Physical measurements were made of these environments. The air velocity was greater in the wire pens and the air temperatures were lower; in the other pens the heavy wooden fences radiated an excessive amount of heat.

ELLIOTT, R. C. Steer feeding trials. *Rhodesia Agric. J.*, 1954, 51, 263-270. [*Henderson Res. Stat.*]

The trial was made to determine the productive potential of Napier grass silage and the supplements necessary to achieve different rates of growth of 4-year-old Hereford steers weighing about 1000 lb. The production of the steers in terms of beef under conventional and modified Rhodesian methods of feeding was also studied. Five comparable groups of 10 animals each were used. The control group was slaughtered at the beginning of the trial. The remaining 4 groups were fed as follows: silage to appetite plus veld hay; silage plus legume hay; silage plus legume hay and limited concentrates; silage plus legume hay and up to 8 lb. concentrates. The silage contained 8 per cent. crude protein on a dry matter basis. The trial lasted 140 days. The animals receiving concentrates were slaughtered as they reached the required degree of fatness. The remaining animals required a further 100 days of vlei grazing before they were ready for slaughter. Carcase measurements of control and concentrate-supplemented groups were taken after slaughter. A loin sample joint from each animal was dissected into bone, muscle, intramuscular and subcutaneous fat.

From the results it was estimated that a daily intake of 50 to 60 lb. silage provided little more than maintenance. The daily rate of gain of the group fed on silage and legume hay was nearly double that of the group on silage and veld hay. The poor results in the latter group were attributed to deficiency of protein and total digestible nutrients. The daily rates of gain of the limited-concentrate and full-concentrate groups were, respectively, 1.53 and 2.08 lb.

On the assumption that the sample joints taken were indicative of carcase composition, it was found that of the total cold dressed weight increase over the feeding period 50 to 60 per cent. was fat and 30 to 40 per cent. muscle. Fat deposition was highest in the group with the highest rate of gain.

From a discussion of the economic aspects of the trial it was concluded that the feeding of the type of steer used was uneconomic and that a greater economy of feed utilisation would be obtained if the available feed was used for younger stock which have had no serious setback during their lives.

DUTTSMAN, W. W. and KESSLER, F. B. Beef cattle feeding and breeding investigations for 1952-53. Round-up report No. 40 (a progress report). *Kansas Agric. Exp. Stat. Circular* No. 298, April 1953, pp. 15. [Fort Hays Branch, Hays, Kans.]

Trials were made to compare different protein and roughage supplements for wintering beef calves; to assess the value of antibiotics in winter rations for healthy calves, and calves suffering from haemorrhagic septicaemia (shipping fever); and to compare different milo grains combined with Ellis (sorgo) silage and cottonseed meal, or sorgo silage with other roughages, for fattening bullocks. The influence of sire on the efficiency of feed utilisation was also under investigation. The report deals only with the results of one year, 1952-53, and must be regarded as a progress report.

In the first test, alfalfa was the best protein supplement both on pasture and in dry lot. It cost more to winter calves on pasture than in dry lot with silage. Wintering on straw was uneconomical.

Calves in dry lot gained slightly more weight and cost slightly less to feed per unit of live-weight increase when receiving a supplement of aureomycin or bacitracin. Neither aureomycin nor terramycin, however, significantly improved the performance of calves which had had a setback because of shipping fever.

Midland milo grain was better than Martin milo grain and sorgo silage was better than sweet clover-kochia silage for liveweight increase of 2-year-old bullocks. Similarly, western wheatgrass hay and prairie hay were inferior to sorgo silage.

The investigations on the influence of the sire have not been going on long enough for conclusions to be reached.—T. D. Bell.

2877

HUGHES, G. P. The production and utilization of winter grass. *J. Agric. Sci.*, 1954, 45, 179-201. [Grassland Res. Inst., Hurley.]

Four series of trials made over the years 1946-1953 inclusive have shown that it is possible to maintain condition in beef cattle grazing through the winter on pasture rested during late summer and autumn. Yields of pasture herbage during the winter were generally of the order of 1500 to

N.A. and B., April 1955

2500 lb. dry matter per acre with approximately 17 to 10 per cent. crude protein. Sowing and maintaining grass and lucerne in alternate rows one foot apart allowed maintenance of the legume over successive seasons and good summer production between periods of winter grazing.

Male Hereford cattle were slaughtered at about 15 months of age and 900 lb. liveweight. No difference in feed economy of gain and carcass quality was found between those castrated at 1 or 7 months of age. Uncastrated animals gained significantly faster and required less feed per unit of gain. Dressing percentage and market grade were lower, but owing to reduced fat cover there was a larger proportion of edible meat, only slightly less tender and without undesirable flavour. Castration at 7 months (weaning) would allow more accurate selection of calves for breeding.—J. L. Corbett.

2884

BURRIS, M. J., BOGART, R., OLIVER, A. W., MACKEY, A. O. and OLDFIELD, J. E. **Rate and efficiency of gains in beef cattle. 1. The response to injected testosterone.**

PIERCE, C. D., AVERY, H. G., BURRIS, M. and BOGART, R. **2. Some factors affecting performance testing.** *Oregon Agric. Exp. Stat. Tech. Bull.* Nos. 31 and 33, July 1954, pp. 35 and 32.

1. Hereford cattle were individually fed on a concentrate and hay ration to appetite, 6 bullocks and 6 heifers being treated as controls and 12 similar animals receiving intramuscular injections of 1 mg. testosterone per kg. bodyweight weekly during growth from 500 to 800 lb. liveweight. Heifers showed an immediate response to the injections, gaining 0.52 lb. daily more than the control heifers. All the bullock calves gained at a faster rate than the heifers throughout, but the effects of testosterone on the bullocks became marked only over the final 125 lb. of liveweight increase. Total digestible nutrients required per 100 lb. liveweight gain were on the average 513 and 401 lb. for control heifers and bullocks, respectively; requirements of the injected animals were 381 and 395 lb., respectively. Analyses of sample joints suggested that this improved efficiency was caused by proportionately greater gains of protein than of fat. In both sexes the proportion of hindquarter meat was reduced. Heifers gave a lower, steers a higher killing-out percentage. Testosterone also increased thyroid and adrenal weights and increased the thyro-tropic hormone content of the pituitary gland measured by chick assay. Palatability and cooking quality of the meat were unaffected, though masculine characters developed in the animals.

2. Hereford calves born in the spring and early summer were subjected to a 120- to 180-day test feeding period during the following winter. Birthweight, gains during the suckling period, and age and weight at the start of the test period (independent factors) were related to rate and economy of gains during the test period, and to gains per day from birth to the end of test, by multiple correlations. Birthweight had a significant positive effect on weight gains throughout. The other independent factors also affected gains during the test period and must be standardised for official testing.—J. L. Corbett.

- WILHELMY, H. Die Viehzucht im Karibischen Küstenland Columbiens. [Cattle raising in the Caribbean coastal area of Colombia.] *Ztschr. Tierzücht. Züchtungsbiol.*, 1954, 63, 201-222. [Kiel.]

The geography and climate of Colombia are briefly described. The Caribbean coast belongs to the *tierra caliente*, without rain from mid-December to mid-April and with a total rainfall of 386 to 1500 mm., with corresponding transition from thornbush and cactus to dry forest and rain forest. A third of the 14 million cattle in Colombia are in this area, on holdings from 5 to 50,000 hectare.

Much of the land is still cleared and cropped in traditional manner by a sequence of *colonos* who hold a small area of 1 to 2 hectare for 18 months at a time, but all types up to completely mechanised farming are to be found. The colono system is merely a transition stage to the establishment of cattle pastures with lucerne or guinea grass, or Yaraguá-Uriva grass (*Hyparrhenia rufa*) or Pará

grass (*Panicum barbinode*) according to the temperature and rainfall. There are also pastures inundated during the rains to which herds are transferred as soon as possible.

Carrying capacity is limited in some areas by water supply but great progress is being made in the creation of collecting ponds and the sinking of wells. The dairy herds are chiefly of Holstein, and Criollo cattle with Zebu crosses and, recently, some crosses with Santa Gertrudis. A detailed description is given of a big hacienda which carries about 1000 head of cattle, with grazing, cut grass, silage of green millet, and with elephant grass and oil cake for the dry season.

Further from the coast cattle are kept for beef, Criollo, Aberdeen-Angus, Red Polled and Romo-Sinuano, with Zebu and Santa Gertrudis crosses. Water and transport constitute the problems and an experiment in local cold storage has not been a success.—I. Leitch.

2892

- YEATES, N. T. M. Environmental control of coat changes in cattle. *Nature*, 1954, 174, 609-610. [C.S.I.R.O., Brisbane.]

Shorthorn calves were divided into 2 groups of 4 animals each. The groups received identical rations. Treatment consisted in reversing the seasonal trend of exposure to light by artificially lighting the stalls occupied by the treated group. Calves in this group were subjected to a gradually increasing exposure to light from 10 to 16½ hr. Control calves received the daily duration of light normal for the latitude of Brisbane.

Monthly hair samples were taken from standard areas of skin, and any changes were noted. The growth of all calves was satisfactory. Treated calves began to shed hair after 12 weeks of increasing light. The hair of the controls remained firmly attached. Growth of hair on the areas from which samples were taken was much less in the treated than in the control group.

- WHITEMAN, J. V., LOGGINS, P. F., CHAMBERS, D., POPE, L. S. and STEPHENS, D. F. Some sources of error in weighing steers off grass. *J. Animal Sci.*, 1954, 13, 832-842. [Oklahoma Agric. Exp. Stat.]

It is necessary to use standardised procedures in weighing cattle, since the extent of gut fill can greatly effect such data. Under the conditions of the experiment availability of water was relatively more important than availability of pasture as a source of variation. Fasting cattle for 10 to 15 hr. before weighing may increase accuracy, but the measurements should be taken as rapidly as possible to avoid large changes in fill between

those weighed first and last. Bullocks weighing 800 to 1000 lb. lost on the average 1 lb. liveweight every 10 min. during the first 3 to 4 hours' fast.

FLUX, D. S. and PATCHELL, M. R. The effect of undernutrition after calving on the quantity and composition of the milk produced by dairy cattle. *J. Agric. Sci.*, 1954, 45, 246-253. [Dairy Res. Inst. (N.Z.), Massey Coll. P.O., Palmerston North.]

Fourteen sets of monozygous twin cows were used. During an experimental period of 6 weeks from the third to the eighth week of lactation, 1 member of each set was maintained on a normal plane of nutrition while the remaining member of each set was fed on a low plane. Undernutrition was achieved by allowing the low-plane animals only 40 per cent. of the area of pasture grazed by the normal-plane animals and only 40 per cent. of the silage supplement. From the eighth week to the end of lactation both groups received the same treatment. Bodyweights were recorded. Milk was weighed daily and samples were taken for the estimation of butterfat, total solids and total protein.

During the experimental period the normal-plane cows gained on the average 13 lb. in weight while the low-plane cows lost 34 lb. Milk production of the normally treated animals was higher than that of their low-plane twins over the 6-week period. The milk of the well fed cows had a lower percentage of butterfat and a higher percentage of solids-not-fat and total protein than that of the poorly fed cows. Milk and butterfat production

of the 2 groups over the whole lactation did not differ significantly, but the average percentage of solids-not-fat in the milk of the well fed animals was significantly higher than that of the low-plane animals over the same period.

Differences in butterfat percentage during the experimental period were highly correlated with weight changes.—J. N. Aitken.

HESELBARTH, K. Untersuchungen über Fresslust, Futteraufnahmevermögen und Futterverwertung bei Milchkühen. [Appetite, capacity and utilisation of feed by dairy cows.] *Arch. Tierernährung*, 1954, 4, 145-195. [Inst. Tierzucht, Justus Liebig Hochsch., Giessen.]

Earlier studies are reviewed. The experiments were made on the college farm, "Oberer Hardthof", on 19 cows, of which 16 were usually in condition for experiment at one time. They were individually fed. Nine of the cows calved during the study. All had 7 kg. hay in 2 portions and different combinations of beet, sugar beet slices, silage, brewer's grains and concentrates. Eight different concentrate mixtures were used, 7 of normal type and 1 with 249 g. digestible crude protein per kg. which was the Lüneberg stud herd mixture. It was used to test effects on appetite, as were minerals or fennel strewn on the concentrates. Capacity was measured in two 1-day tests with a mixture of dried red beet (steeped), dried sugar beet slices and Steffen slices in the ratio of 1:3:8:11 given in 20-kg. portions to complete satiety. Appetite was assessed as speed of eating.

Difficulties of interpretation were introduced by differences, in relation to calving and the peak of milk yield, of the stage at which tests were made, and by the use of an unfamiliar feed for capacity measurements.

The norms suggested by Svoboda (*Proc. XIII World Dairy Congress*, 1937, Vol. 1, p. 168) were compared with feed eaten, with little agreement. Feed eaten was related to size and milk yield but not closely, as assumed by Svoboda. Rate of eating, in g. dry matter per min., which varied from 50 to 150, in spite of considerable day-to-day variation was considered characteristic of individuals and a useful measure of appetite. Greed, induced by feeding half the group 10 min. before the rest, had little or no effect on rate of eating; this is attributed to individual feeding and hence lack of competition. Chalk sprinkled on concentrates depressed appetite and fennel stimulated it, but not sufficiently to offset the cost. The Lüneberg concentrate mixture was more acceptable than the others.

It is suggested, subject to confirmation of the results of these experiments, and repetition of the experiments with young stock, that a young herd

might be divisible into 3 classes, those that eat less than 60, from 60 to 100 and over 100 g. dry matter per min., and that those that eat least might be eliminated as unlikely to become high producers.

BALCH, C. C., BALCH, D. A., BARTLETT, S., JOHNSON, V. W., ROWLAND, S. J. and TURNER, J. Studies of the secretion of milk of low fat content by cows on diets low in hay and high in concentrates. 4. The effect of variations in the intake of digestible nutrients. *J. Dairy Res.*, 1954, 21, 305-317. [Nat. Inst. Res. Dairying, Univ. Reading.]

The experiment was made on 5 Shorthorn cows during a period of 18 weeks. The rations were of hay and one of two types of concentrate. One of the concentrates was of the war-time type sold in the form of cubes as National Cattle Food No. 1; the other was a simple mixture of flaked maize, wheat feed and decorticated groundnut meal.

The experiment was divided into 4 periods. In the preliminary period the cows received daily 20 lb. of hay and the concentrate cubes at the rate of 4.5 lb. per gal. milk. In period 2 the hay was gradually reduced to 4 lb. daily, the remainder of the requirements being met by an extra amount of cubes. In period 3 the hay allowance was kept at 4 lb. and the cubes were replaced by a smaller amount of the concentrate mixture. In the final period the hay allowance was increased to 18 lb. and the concentrate mixture was given at the rate of 4 to 5 lb. per gal. milk.

Digestibility trials were made during periods 1 to 3. Rate of passage of the hay through the alimentary tract was measured by a method previously described (Abst. 1370, Vol. 25). Milk production was recorded and fat estimations were made. Starch equivalents were calculated from the percentage of digestible nutrients found.

The fat content of the milk was unaffected when extra concentrates in cube form were given with a reduced amount of hay. There was a loss of over 30 per cent. in the yield of fat when the cubes were replaced by the concentrate mixture in period 3; at the same time there was a rise in the solids-not-fat content of the milk, owing to an increase in milk protein. Butterfat and solids-not-fat of the milk returned to normal when the normal diet was restored.

Digestibility trials indicated that the fall in fat content was not due to changes in the amounts of

dry matter, crude protein, ether extract, crude fibre, cellulose, cellulose or pentosans or in cellulose digested. The main difference between the diets in periods 2 and 3 was that the concentrate mixture provided a large intake of starch and lacked the physical property of "fibreousness". It was concluded that a combination of these affected the physical and biochemical processes of the reticulo-rumen and thus indirectly caused a depression of milk fat.

It was found that hay remained for an abnormally long time in the reticulo-rumen when the low-hay diet was given. There was a fall in the digestibility of crude fibre when the concentrate mixture was given with a limited amount of hay.

Throughout the period of the trial starch equivalent intakes were close to standard requirements but there was a surplus of digestible crude protein.

MARTIN, T. G., STODDARD, G. E. and ALLEN, R. S.

The effects of varied rates of hay feeding on body weight and production of lactating dairy cows. *J. Dairy Sci.*, 1954, 37, 1233-1240. [Iowa Agric. Exp. Stat., Ames.]

Twenty Holstein cows were used in 2 trials to compare 4 levels of hay feeding. The hay was fed at rates of 0.50, 1.17, 1.83 and 2.50 lb. daily per 100 lb. liveweight. A concentrate mixture of ground maize, ground oats, soya bean oilmeal and steamed bonemeal was given in amounts sufficient to supply 100 per cent. of Morrison's recommended standard at each level of hay feeding. There was no significant effect of level of hay feeding on body-weight or on milk production when total digestible nutrients or estimated net energy was held constant. The digestibility of protein and dry matter fell as the hay content of the ration increased.

BURT, A. W. A., BARTLETT, S. and ROWLAND, S. J.

The use of seaweed meals in concentrate mixtures for dairy cows. *J. Dairy Res.*, 1954, 21, 299-304. [Nat. Inst. Res. Dairying, Univ. Reading.]

In an experiment with 18 Ayrshire cows the effects on milk composition and yield of 3 concentrate mixtures were compared. Seaweed meal made from *Ascophyllum nodosum* or *Laminaria cloustoni* was incorporated in 2 mixtures so as to supply 10 per cent. of the total. The third mixture was similar except that the seaweed meals were replaced by 8.75 per cent. of an oatmeal by-product plus 1.25 per cent. NaCl. The basal ration of all cows consisted of 30 lb. marrowstem kale and 18 lb. hay. The concentrate mixtures were given at the rate of 3½ lb. per gal. over the first gallon and a half, for periods of 3 weeks. No effect on milk yield or butterfat percentage was

seen. When the oatmeal by-product was given the milk had a higher solids-not-fat content. It is concluded that the use of seaweed meals in dairy rations can have only a limited value.

MARSHALL, S. P., SANCHEZ, A. B., SOMERS, H. L. and ARNOLD, P. T. D. Value of pearl millet pasture for dairy cattle. *Florida Agric. Exp. Stat. Bull.* No. 527, October 1953, pp. 20. [Gainesville, Fla.]

The feeding value of pearl millet (*Pennisetum glaucum*) for lactating Jersey and Guernsey cows and growing heifers under the dairying conditions of Florida was ascertained from trials extending over 3 summers. Estimates of the total digestible nutrients per acre and of the seasonal distribution of the feed supply from the grazings were also made.

In the spring of each year three 2-acre pastures were sown after winter oat grazing on the areas had finished. The pastures were maintained in good order by rotational grazing, mowing the stubble and top dressing with nitrogen fertilisers. In the third season forage samples were analysed for crude protein and dry matter. A concentrate mixture was given at the rate of 1 lb. per 3.5 lb. of fat-corrected milk produced.

The length of the grazing season ranged from 100 to 123 days and was influenced by the date on which grazing began. The productivity of the pastures began to decline at the end of August and grazing was discontinued by mid-September in each year. The dry matter content of the samples ranged from 12.3 to 15.8 per cent. and the crude protein from 2.88 to 3.69 per cent. on a fresh basis. The average carrying capacity of the pastures over the 3 seasons was 2 cows per acre. The average production of total digestible nutrients was 2112.7 lb. per acre. Bodyweights of the cows were maintained with only slight fluctuations. Milk production even at high levels was also maintained during grazing.

To ascertain the feeding value of millet for growing heifers a similar trial was made over the same period as in the first trial. The pastures were established on poorly drained land. The average yield of total digestible nutrients per acre was only 1660.1 lb. It was shown that heifers over 10 months of age in good condition gained at rates above normal for their ages. Small or thin heifers in the same age group grew at subnormal rates. A discussion of the economic aspects of the trials showed that millet pastures could, with profit to the farmer, be fitted into the farm rotation.

2904

VAN KOETSVELD, E. E. and SWART, F. W. J. Suikerpulp vergeleken met gewone droge pulp in het rantsoen voor melkkoeien. [Sugar

Vol. 25, No. 2

pulp compared with ordinary dried pulp in the ration of milk cows.] *Inst. Moderne Veevoeding "De Schothorst"*, S43, pp. 7. English summary.

Sugar pulp is either the dry residue of the Steffen process, or ordinary pulp mixed with juice containing sugar and dried. Both contain 35 to 40 per cent. sugar and keep very well. Or, according to the official definition, dried sugar pulp is dried slices from which less than the usual amount of sugar has been removed; it contains not less than 25 per cent. sugar. Wet pulp is the residue from the leaching of sugar beet slices, with 90 per cent. water and 0.3 per cent. sugar. If lime has been added, the dried product (11 to 13 per cent. moisture) may contain 2.68 per cent. Ca. The K content is low. It is greedily eaten. Many farmers believe that sugar pulp improves both milk yield and percentage fat in milk, and is worth its higher price.

A feeding trial was made with 16 milk cows and 2 heifers in 2 matched groups. The ration for the cows was 5 kg. hay, 3 kg. dried pulp, 30 (later 25) kg. ensiled mangolds with leaves, and, according to milk yield, a concentrate mixture of oilseed meals, cereals, minerals and a preparation of vitamins A and D₂. The heifers had 2 kg. pulp and 20 kg. mangold silage.

The average milk yield in kg. and percentage fat in milk of the 8 cows given sugar pulp, in the pre-period, experimental (40 days) and post-period were: 19.1 and 3.61, 17.3 and 3.70 and 16.0 and 3.88; in the control group, 18.7 and 3.63, 17.6 and 3.70 and 16.2 and 3.85. There was no apparent difference between the ordinary and sugar pulp.—I. Leitch.

SCOTT, I. W. and WILSON, G. B. Effect of month of calving on production. *N.S.W. Dept. Agric. Sci. Bull.* No. 74, 1954, pp. 19.

The data relate to complete lactations of 29,044 Jerseys and 9388 Australian Illawarra Shorthorns. For this purpose New South Wales dairying districts were divided into 5 zones. Data for each zone and for each breed within each zone are given separately. Tables show for each month the average length of lactation of all cows calving, the average production of butterfat and the percentage of cows calving. The data thus presented are compared with graphs showing the percentage chances of receiving rainfall equal to or greater than the effective amounts for each month.

Cows calving in the 2 months preceding the highest seasonal rainfall had the longest lactations and highest production. It was estimated that increasing the percentage of cows calving in those months would greatly increase total butterfat production.—J. N. Aitken.

FASSEBENDER, J. P. Futterbeschaffung und Fütterung in den Abmelkwirtschaften des linksrheinischen Bezirks Köln. [The supply of feed for and the feeding of flying herds in the District of Cologne on the left bank of the Rhine.] *Arch. deutsch. Tierzucht*, 1954, No. 32, pp. xii + 136. Josef Vienerius, Münster, Westphalia. [Inst. Tierzucht Tierfütterung, Univ. Bonn.]

The subject of this thesis (*Univ. Bonn*, 1953) is dairy farming in the part of the Cologne *Bezirk* on the left (west) bank of the Rhine. The survey is based on 204 of 250 farms studied. Of the 204 herds, 98 were flying herds (*Abmelkbetriebe*) retained for one lactation only (on the average 11 months) and sold for slaughter (average size of holding, 71 ha.: 1 ha. = 2.47 acres). Six were *Abmelk-Mastbetriebe* (124 ha.), i.e., of cows bought non-pregnant in declining lactation and fed lavishly so that their milk would pay for their feed. Seventy were *Durchhaltebetriebe* (54 ha.), i.e., of young cows bought in full milk and carried through several lactations (on the average 2½ years). Eighteen were *Durchhalte-Nachzuchtbetriebe* (71 ha.), in which calves from the best cows are reared, but not enough for replacement (cows in milk on the average for 2½ years).

After introductory sections on the soils and climate of the region and the distribution of the different types of herd, a detailed analysis is made

of farm practices: crops grown for fodder, proportion of land devoted to these, pasture and its management, fodder conservation and purchased feeds. The economics of the different systems is discussed. Finally, feeding practices are described and a number of typical rations are given and others are suggested. The results are presented in 63 tables, 28 diagrams and 4 maps, and the summary occupies 5 pages.—W. M. Deans.

2911

KHISHIN, S. S. and EL-ISSAWI, H. F. The Jersey in Egypt. *Empire J. Exp. Agric.*, 1954, 22, 121-127. [Dept. Animal Husb., Fac. Agric., Ibrahim Univ., Shebin el Khom, Egypt.]

The performances of pure and grade Jersey cows under Egyptian conditions were compared. The grades were obtained by using a Jersey bull on native cows and back-crossing the F₁ generation to Jersey bulls to obtain higher grades. Data from 155 lactations of 34 pure Jersey cows and from 141 lactations of 31 grade Jersey cows were used.

Milk production of both types was found to be superior to that of native cattle when the average lactation yield of a well managed group of native cattle was taken to be 3000 lb. Total milk yield, 305-day yield and 70-day yield of the F₁ Jersey × native crosses approached that of the pure Jerseys. Length of lactation increased as the amount of Jersey blood increased. The breeding efficiency of both pure and grade Jerseys was high. The performance of the animals used in this study was superior to that of Friesians, Shorthorns and their grades as reported by other investigators. It was concluded that crossing the native cattle with Jerseys was more beneficial than with Friesians or Shorthorns.—J. N. Aitken.

LENKETT, W. Zur Calcium-Phosphorversorgung während der Laktation. [Supply of calcium and phosphorus during lactation.] *Arch. Tierernährung*, 1954, 4, No. 4, Beihefte, 11-18. [Inst. Tierphysiol., Univ. Göttingen.]

The Ca and P requirements of dairy cows are discussed in relation to the mineral reserves. It is estimated that in a cow of 500 kg. bodyweight, with total body Ca and P stores of about 8500 and 4500 g., about 17.4 and 17.7 per cent. of these amounts may be regarded as mobilisable reserves. With 50 per cent. utilisation of feed Ca and P the gross requirements are estimated to be 30 to 32 g. Ca and 20 to 25 g. P daily for maintenance and 2.5 g. Ca and 1.8 g. P for each kg. milk of 4 per cent. butterfat. For practical purposes values of 5 to 6 g. Ca and 4 to 5 g. P per 100 g. digestible crude protein of the ration are suggested.

N.A. and R., April 1955

The feeding of dairy cows on 8 farms in South Hanover was studied, on 5 of these farms for a year. Crude protein, starch equivalent, Ca, Mg, P, K and crude fibre values are tabulated. All the rations supplied ample Ca on the basis discussed above, but few supplied enough P, in spite of the relatively high P content of the concentrates used. The values were usually about 2.4 to 3.5 g. P per 100 g. digestible crude protein. A mineral mixture with a Ca:P ratio of about 1.5:1 is recommended.—D. Duncan.

JOUBERT, D. M. The influence of high and low nutritional planes on the oestrous cycle and conception rate of heifers. *J. Agric. Sci.*, 1954, **45**, 164-172. [Sch. Agric., Univ. Cambridge.]

This investigation was made with heifers of the Shorthorn, Afrikaner, Friesian and Jersey breeds. Within each breed the heifers were divided into related pairs of the same age. Some of the pairs were dizygotic twins. One member of each pair was reared on a continuous high plane of nutrition and received supplementary feeding during winter when the supply of nutrients from natural pasture was insufficient for their needs. The other members of each pair were maintained on natural pasture and received no supplement. The Afri-

kaner and Shorthorns were treated as beef types and the Friesian and Jersey as dairy types. Within each type all animals received the same treatment after calving. Sexual activity was studied by recording oestrus data. There was no significant difference between high- and low-plane animals in the length of the dioestrous cycle. Friesian heifers tended to have longer cycles than those of the other breeds. In both groups 95.6 per cent. of the cycles fell within the normal range of 17 to 23 days.

The majority of the high-plane heifers reached sexual maturity in winter; 85.7 per cent. of the low-plane heifers came on heat for the first time in the summer. Onset of puberty in the low-plane groups was delayed on the average by 9.6 months. Even after puberty was reached low-plane animals tended to show anoestrus during subsequent winters. After calving high- and low-plane beef type animals required, respectively, 266 and 414 days before resuming normal sexual activity. High-plane dairy type heifers showed oestrus approximately 3 months after calving; the low-plane heifers required a slightly longer interval. Conception rates of the low-plane heifers were better than those of the high-plane.—J. N. Aitken.

CARNEIRO, G. G. and LUSH, J. L. Reproductive rates and growth of purebred Brown Swiss cattle in Brazil. *J. Dairy Sci.*, 1954, **37**, 1145-1157. [Dept. Animal Husb., Iowa State Coll., Ames.]

Data for this study were obtained from the Brazilian Brown Swiss Herd Book and from detailed records kept at 5 state experimental or demonstration farms. In Brazil the cattle are

reared almost wholly on grass. The general practice is to hand-feed only during the dry season. The feeds consist of silage, grass hay, chopped sugar cane and small amounts of concentrates. The general standard of management is low.

At 2 of the publicly owned farms 80 per cent. of the calvings occurred during the dry season. At the other 3 farms the cows were mated to calve at all seasons. Herd book records showed that of 863 purebred calves born 52.1 per cent. were males. Mortality records showed that 40 to 50 per cent. of the calves born did not reach breeding age. The most important causes of death were abortion, stillbirths, tick fever, pneumonia, congenital debility and foot-and-mouth disease.

Sires and dams were 61.5 and 77.3 months of age, respectively, when their offspring were born. From this the generation interval was calculated to be 5.75 years. The annual replacement rate for cows was 21 per cent. The average age of heifers at first calving was 44 months. The growth rates of Brazilian Brown Swiss were below the generally accepted U.S. standard.—J. N. Aitken.

JOHANSSON, I. An analysis of data from the Danish bull progeny testing stations. *Ztschr. Tierzücht. Züchtungsbiol.*, 1954, 63, 105-126. [Inst. Animal Breeding, Royal Agric. Coll., Sweden.] German summary.

This paper is based on the data from Danish bull progeny testing stations over several years, relating to the progeny of 174 Danish Red bulls. The efforts made to reduce environmental differences are described, but in spite of these, differences between years and stations account for large proportions of the differences between groups with respect to bodyweight, milk yield and butterfat percentage. It is suggested in this connection, referring to an analysis made of weight: girth index, that probably the largest error in the Danish progeny test is due to differences in the nutritional status of the groups on their arrival at the stations.

It is also pointed out that the method of comparing bulls directly on the performance of their daughters, without reference to their dams, may be misleading if there has been selection of the daughters to make up the progeny groups; this is

particularly true of selection with respect to their dams' butterfat percentage. This appears to be present to a certain extent.

The question of selection of the bulls also arises in considering whether the 174 tested can be considered a random sample of the breed. The high variability between progeny groups tested in the same year, and at the same station, does not indicate any selection of the bulls on the basis of their ancestors' performances. The lack of correlation between butterfat yield of the bulls' dams and of their daughters further indicates that effect of bull selection on variation in yield between progeny groups may be neglected.

Analyses of bodyweight and the yield of 250 days' lactation indicate that bodyweight, milk yield, butterfat percentage and butterfat yield are heritable characteristics. The degree of heritability of milk and butterfat yield are higher than the results obtained from field data. While some of this is considered to be due to the standardisation of environment mentioned above, it is felt that the results here may have been exaggerated somewhat by including differences due to nutritional status on arrival along with the true genetic differences between progeny groups. The magnitude of this error cannot be estimated.

In addition, it was found that the better the state of nutrition at calving, then the higher would milk and butterfat yield be, on the average. On the other hand, the best milkers lost most weight during lactation, and vice versa.

Finally, it was demonstrated that it was almost twice as efficient to test bulls simultaneously at the same station as to do so in different years and at different stations.—A. W. Boyne.

CHARLET-LERY, G., LEROY, A. M. and ZELTER, S. Z. Élevage artificiel de l'agneau précocement sevré. Essai de détermination de ses dépenses de croissance. [Artificial rearing of the prematurely weaned lamb. Estimation of growth

requirement.] *Ann. Zootech.*, 1954, 3, 169-187. [Lab. Recherches Zootech., Inst. Nat. Agronom., Paris.]

In 2 experiments 12 purebred Île-de-France lambs were used, 4 males and 2 females in each experiment. Each animal was a twin and the

N.A. and R., April 1955

other twin was left with the ewe, though it could not serve as control because it now received more than the usual amount of milk. In the first experiment the 6 lambs, born between 3 and 16 November, were gradually weaned in the first week of December and studied until they were 82 days old. The other group, all born on 17 April, were weaned abruptly when 17 days old and studied until 100 days. The diet which replaced the ewe's milk consisted of chopped alfalfa hay of excellent quality and a granular concentrate mixture containing, per cent., barley 48.4, oats 11.4, bran 7.6, linseed cake 9.1, soya bean cake 5.3, dried distiller's yeast 7.6, dried skimmed milk 7.6 and salt mixture 3. Towards the end of the experiment the lambs received soaked beet pulp. In the first experiment the concentrate ration was mixed with 25 per cent. rolled oats during the week of weaning, to reduce the protein intake. Vitamins A and D were given separately by mouth.

There was no digestive upset. Growth was retarded in the first 2 weeks and the lambs weaned abruptly even lost a little weight, but after this it was not significantly slower than the recorded mean for the breed.

The initial setback was much worse in the males than in the females, and it is recommended that males intended for breeding should not be weaned prematurely.

Group digestibility trials made in the second experiment indicated that the growth requirements of these lambs were of the same order as those of normally fed lambs.—D. Duncan.

LARGE, R. V. and TAYLER, J. C. *Studies on the growth of Clun lambs.* *Empire J. Exp. Agric.*, 1954, 22, 141-147. [Grassland Res. Inst., Hurley, Berks.]

Weights of 54 Clun lambs and skeletal measurements of 36 of these were recorded from birth to 20 weeks of age. Ram singles were heavier and of greater skeletal size than ewe singles at birth and 20 weeks. Ram twins were heavier than, but almost the same size as, ewe twins. From birth to 20 weeks, late maturing parts increased greatly in size: width of hooks 139 per cent., depth of chest 86 per cent., length of pelvis 93 per cent. and width of hips 98 per cent. Early maturing parts such as length of hind cannon and circumference of fore cannon increased by 44 and 34 per cent., respectively. Ewe lambs tended to reach better conformation at an earlier age than wethers. Sixteen of the lambs were reared on a low-plane diet indoors and the ratio

$$\frac{\text{width of hooks}}{\text{length of hind cannon}} \times 100$$

Vol. 25, No. 2

shows the effect of this on conformation at 20 weeks. [Width of hooks is the horizontal distance between the 2 *tuber coxae* of the pelvis and length of hind cannon the distance between the condyles of the metatarsals and the posterior end of the heel bone.] The ratio in the low-plane lambs increased from 48 at birth to 76, compared with an increase of 45 to 81 in the high-plane.—J. C. Gill.

WILLIAMS, S. M. *Fertility in Clun Forest sheep.* *J. Agric. Sci.*, 1954, 45, 202-228. [Univ. Coll. Wales, Aberystwyth.]

Fertility of Clun sheep was recorded in a 2-year detailed study of 3 flocks under different conditions of environment and management, with fertility and management statistics from over 100 flocks. In 1950 barrenness in ewes was 3.5 per cent., tending to be highest in small flocks, and in ewe lambs 43.8 per cent., rising with flock size. Including abortions the figures were 4.6 and 51.4 per cent., respectively. In 1951 barrenness in ewes was 3.3 per cent. and in ewe lambs 32.1 per cent. Multiple births in all flocks for the 2 years were as follows: twins 52.5 and 58.7 per cent. in ewes, 12.7 and 28.9 per cent. in ewe lambs; triplets in ewes 3.9 and 6.7 per cent. There was a highly significant correlation between percentage of twins in 1950 and in 1951 and between percentage triplets in 1950 and 1951 for ewes but no significant correlations between twinnings in successive years for ewe lambs. In ewes' lambs, mortality showed much more seasonal variation than flock variation. In ewe lambs' lambs the opposite was the case. There appeared to be a negative correlation between flock size and flock fertility. Flushing affected the fertility of ewes but not of ewe lambs. It did not affect barrenness. The most important fertility component in influencing lambing percentage in ewe lambs was barrenness, and in ewes, percentage twins. In most Clun flocks no selection of ewe lambs before mating is made, and although this early breeding tends to depress subsequent fertility it does not affect the liveweight of the ewe lambs and has resulted in a certain amount of selection for earlier sexual maturity and greater fertility.—J. C. Gill.

The performance of 24 Blackface ewe lambs wintered off the farm on lowland grassland from October to April was compared with that of a similar group wintered on unimproved hill grazings. The lambs wintered away gained 6.8 per cent. in weight and the home wintered lambs lost 14.8 per cent. over the 6-month period. Both groups

were run on the hill grazing from April to November and at the end of this period there was no significant difference in weight between the groups. The 7 lightest sheep of the group wintered away were, however, significantly heavier ($P < 0.05$) than the 7 lightest of the home wintered group. An inverse relation was found between the original weight of the lambs wintered away and their weight gain during the winter. There was a difference of only 7 per cent. in fleece weight in favour of the lambs wintered away. It is suggested that it might be of advantage to winter away only the lightest lambs and at least 15 per cent. weight increase is required to raise the average size of the lambs wintered away permanently above that of those wintered on the hill.—J. C. Gill.

Seventy-three lambs of the Rahmani and Ossimi breed born between October and March proved superior in all respects to 67 lambs born during summer. Differences in both weight and body measurements at birth and weaning were statistically significant. These findings are explained by the fact that the ewes lambing during winter are in better condition before lambing time and thereafter than those lambing in summer.

197-234. [Inst. Animal Genetics, Edinburgh.] German summary.

A study of the heritability of economic characters and recommendations on breeding methods for their improvement is reported. The chief products are surplus lambs and milk; the average milk yield in 442 recorded lactations with a mean length of 250 days was 231 kg. The main feeds are roadside and other rough grazing in summer, and hay, vine haulms and straw in winter when the sheep are housed.—J. L. Corbett.

RENDEL, J. De viktigaste produktionssegenskaperna hos får-variation och nedärvning. [The most important characteristics relating to productivity in sheep, their variation and inheritance.] *Kgl. Lantbruksakad. Tidskr.*, 1954, 93, 282-319. [Lantbrukshögsk. Inst. Husdjursgenetik.] English summary.

The review is in 3 main sections, reproduction, birthweight and growth of the lamb and yield and quality of wool. Points discussed under the first are: the time and length of the reproductive season, the reproductive cycle, duration of pregnancy, fertility and milk production. Fertility depends on the proportion of infertile ewes, which is high in the first year and averages about 5 or 6 per cent. in later years. The number of lambs born depends chiefly on the age of the ewe, her weight, her food supply, and her genetic make-up. Apart from inheritance the progress of lambs depends on birthweight and milk supply, and the yield and quality of wool depend also on feeding and age.—I. Leitch.

JAYARAMAN, S. and MAHAL, G. S. Relationship of clean wool yield with body weight and body size in Bikaner ewes. *Indian J. Vet. Sci.*, 1954, 24, 143-150. [Govt. Livestock Farm, Hissar.]

In a trial with 341 Bikaner ewes ranging from yearlings to 7-year-old ewes significant positive correlations were found between bodyweight and clean wool yield (adults 0.257, yearlings 0.587) and between body size (length \times chest girth) and clean wool yield (adults 0.225, yearlings 0.201). It is concluded that selection of replacement stock at 15 to 18 months for bodyweight will lead to higher wool yields.—J. C. Gill.

EPSTEIN, H. The fat-tailed sheep of Arabia. *Ztschr. Tierzücht. Züchtungsbiol.*, 1954, 63, 381-396. [Jerusalem.]
- The sheep of Arabia are of 2 types: a short-haired fat-rumped type and a fat-tailed type which

is now restricted to the north and centre of the Peninsula. There are 2 breeds, Nejd and Hejáz. The Nejd sheep from the central steppe and desert weigh about 42 (rams) or 40 (ewes) kg., or in the poorest areas as little as 35 kg. A well fed ram may weigh 75 kg. Dressing percentage is 35 to 40 and the mutton is of poor quality. The Hejáz sheep weigh even less, 32 or 30 kg., but they fatten readily, to produce mutton of poor quality with the fat in compact layers. The fleece is hairy, in the Hejáz silky, but not wool. [Yield of fleece is not given.]—I. Leitch.

WUSSOW, W. and WIENIGER, J. H. Die Ausbildung des Magen- und Darmkanals beim Schwein unter dem Einfluss verschiedenartiger Ernährung und die Beziehungen zur Futerverwertung. [Development of the stomach and intestinal canal in the pig as affected by diet and in relation to feed utilisation.] *Arch. Tierernähr.*, 1954, 4, No. 4, Beihefte, 151-181. [Inst. Tierzucht, Martin Luther Univ., Halle, Wittenberg.]

Lehmann (1919) initiated the theory that the ability of pigs to use more fibrous feeds efficiently may be improved by increasing the intestinal capacity by accustoming them early to "ballast". Literature since Lehmann is briefly reviewed. A modified form of the theory is that a diet chiefly of animal feedingstuffs would give a relatively well developed small intestine and an underdeveloped large intestine and a diet of plant feeds the reverse.

In all, 130 pigs were fed and slaughtered in this study, 9 as they attained the weight of 30 kg. on a sucking-pig ration of barley meal and steamed potatoes with fishmeal and yeast; and 30 pigs as they reached the weight of 130 kg. They were of 3 breeds, Veredeltes Landschwein, deutsches Edelschwein and Cornwollschwein. Of the larger group 11 were reared on barley to appetite and meatmeal; 11 on 850 g. barley, meatmeal, and potatoes to appetite; and 8 on 400 g. barley, meatmeal, 2 kg. potatoes, and rye bran to appetite.

The techniques used to measure the intestines are described; for the small intestine length and weight; for the large, weight and volume measured with air.

The results are presented in 5 tables, of which the last is a summary. With the diets in the order barley, potato, bran, the average daily intakes in g. were: ballast 416, 209 and 516; dry matter 2386, 2325 and 2200; total nutrients 1911, 2018 and 1548. The chief measurements of the gut, means in the order of diets above, were: weight of stomach in g. 859, 934 and 950, small intestine 1583, 1862 and 2414, and large intestine 2110, 2082 and 2905; volume of large intestine in litres 9.54, 10.63 and 16.27.

No difference was found between the breeds. The conclusions are that weight and volume of the intestine can be increased by bulky diet and that, if the pigs did not succeed in getting the same amount of nutrients from bran as from barley and potatoes or barley alone, they got more than

if they had not been "accustomed" to bran. Experiments are in progress to show whether still earlier feeding with bran would improve its use.

STORZ, H. Stickstoff- und Schwefelansatz nach reiner Gerstenfütterung bei wachsenden Schweinen, ermittelt durch 10-tägige, in Zeitabschnitten wiederholte Bilanzversuche im Ablauf der Mastzeit. [Retention of nitrogen and sulphur on a diet of barley alone by growing pigs, estimated in 10-day balance experiments at intervals during fattening.] *Arch. Tierernährung*, 1954, 4, No. 4, Beihefte, 38-50. [Inst. Tierphysiol., Univ. Kiel.]

Two littermate Landrace barrows (castrated males) were used for nine 10-day balance trials during 224 days. At first they received barley meal and bran, later barley meal alone, except for 15 days when some fishmeal was added. S and N balances are tabulated.

The mean S : N ratio in the ration was 1 : 11.17 ; the ratios retained by the 2 pigs were 1 : 10.87 and 1 : 11.14, respectively. The percentage N retention tended to rise in the course of the experiment. There was no better utilisation of protein in the period when fishmeal was given.

The results are considered to show that short term N balances are of little value for the study of N metabolism.—D. Duncan.

2959

COEY, W. E. and ROBINSON, K. L. Some effects of dietary crude fibre on live-weight gains and carcass conformation of pigs. *J. Agric. Sci.*, 1954, 45, 41-47. [Queen's Univ., Belfast.]

Five experiments are described, the general object being to study the effects of dietary fibre on carcass conformation independently of its effects through changes in growth rates. In experiments 1 and 1A diets containing 3.5 and 5.5 per cent. of crude fibre were given to pigs on 2 planes of energy intake. Within each plane the effect of fibre on digestibility was compensated for by giving the diet higher in fibre according to a higher scale. In experiments 2, 3 and 4 the "low-fibre diets" contained 3.5 per cent. crude fibre and the high-fibre diets given before and after 150 lb. liveweight contained 8 or 9 and 11.5 or 11.0 per cent. crude fibre, respectively. In these 3 experiments the pigs were on one plane of energy intake ; there was a negative control where the high- and low-fibre diets were fed at the same rate.

In experiments 1 and 1A the small difference between the high- and low-fibre levels caused no significant difference in most carcass measurements, although there were carcass differences between pigs on the 2 planes of nutrition. Pigs

on the high fibre diets had the lower killing-out percentages.

In experiments 2, 3 and 4 pigs fed on the high-fibre diet but on the same level of feeding as others on the low-fibre diet had, in comparison, thinner backfats and lower killing-out percentages. They grew more slowly, and the thinness was, in part, a reflection of slow growth, and the lower killing-out percentage a reflection of younger physiological age. Pigs fed on the high-fibre diet but at the higher rate and therefore on the same plane of energy nutrition as the pigs on the low-fibre diets also had, in comparison, thinner and softer backfat and lower killing-out percentages. These could not have been a reflection of slower growth or younger physiological age. In this case it is suggested that the lower killing-out percentage was due to greater development of gut size in order to deal with the greater bulk of fibre, and that the thinner backfat was in part related to the lower carcass weight.

Raising the level of dietary crude fibre thus caused a change in the distribution of liveweight gains so that at the same slaughter weights pigs on the high-fibre diets had the heaviest offal and lightest dressed carcass weights.

Data from experiments 2 and 3 were recalculated to show the liveweight gains which pigs on the high-fibre diets would have made if their offal weights had been as low as pigs on the low-fibre diets. These calculated gains were much less than the observed gains and showed that the extra feed given to compensate for the fibre content of the diet was largely unremunerative.

- MERTZ, E. T., HENSON, J. N. and BEESON, W. M. Quantitative phenylalanine requirement of the weanling pig. *J. Animal Sci.*, 1954, 13, 927-932. [Dept. Biochem., Purdue Univ. Agric. Exp. Stat., Lafayette, Ind.]

Twelve male pigs averaging 25 lb. were divided into 4 groups and fed individually for a 28-day experimental period. The basal diet was of maize, cerelose, 9 essential amino-acids, minerals, diammonium citrate, liver extract, terramycin and vitamins. It contained 12.6 per cent. crude protein, 0.23 per cent. phenylalanine and 0.14 per cent. tyrosine. Supplements of 0.09, 0.19 and 0.29 per cent. DL-phenylalanine were added to the diet of 3 of the groups. On the assumption that tyrosine replaces phenylalanine on a weight for weight basis the 4 groups thus received in their diets the equivalent of 0.37, 0.46, 0.56 and 0.66 per cent. phenylalanine, respectively. The daily liveweight gains of the groups were 0.55, 0.85, 0.80 and 0.76 lb. and the amount of feed eaten per lb. gain was 3.26, 2.75, 2.78 and 3.01 lb. These figures indicated that the phenylalanine requirement of the weanling pig is 0.46 per cent. of the ration.—I. A. M. Lucas.

- STAHL, W. and LEMCKE, B. Futterbedarf und Schlachtleistung bei Schweinen mit verschiedenem Endgewicht. [Feed requirement and carcass yield in pigs of different slaughter weights.] *Arch. Tierernährung*, 1954, 4, No. 4, Beihefte, 240-255. [Inst. Tierzucht., Dummerstorf, Berlin.]

The 6 pigs were all of one litter and 84 days old when the experiment began. One pig (A) was fed to reach 300 kg., 2 (group B) to 150 kg. each and 3 (group C) to 100 kg.

Pig A received for a year a mixture of 10 parts fishmeal, 10 meatmeal, 10 dried yeast and 70 barley and oatmeal, increasing to 2 kg. daily and made up with roots and chaff or chopped green food to appetite. Fattening was completed with a ration of, per cent., barleymeal 57, potato flakes 38 and protein feeds 5, given to appetite.

Group 2 received for 112 days 0.5 kg. per head daily of the concentrate mixture first given to pig A, 1 kg. potato silage, and roots and chaff or green food to appetite. The concentrates were then increased to 1 kg. daily and potatoes were given to appetite. Group 3 received throughout the experiment 1 kg. concentrates per head daily and potatoes to appetite.

The final total weights of the 3 groups and the times taken to reach them were: pig A, 313 kg., 483 days; group B, 322 kg., 241 days; group C, 329.5 kg., 155 days. The mean daily weight gains were 591, 570 and 594 g.

Pig A gained during the experiment 10 kg. more than the other groups, but groups B and C consumed 73.4 and 65.8 per cent. of the total nutrients and 72 and 76 per cent. of the protein taken by pig A. For each 100 kg. weight gain the 3 groups required, respectively, 567.8, 418.0 and 372.3 kg. dry matter, 42.14, 31.55 and 33.14 kg. digestible protein, and 393.8, 298.9 and 268.2 kg. total nutrients. The total nutrients for production were most economically used by group C, least by pig A, but the most economical use of protein was made by group B and the least by pig A.

Details of the carcasses are given. The ratios of fat to lean in the 3 groups were A, 1:1.86; B, 1:2.36; and C, 1:2.74. For a unit of digestible protein the carcasses of groups B and C yielded 38 and 42 per cent. more fat-free meat than pig A, while for a unit of N-free feed they yielded 10 and 18 per cent. more fat. The value of rapid fattening is thus greatest when judged by carcass criteria and economy in feedingstuffs.—D. Duncan.

2971

PECHT, G. Untersuchungen über die Herstellung von Fischsilagen nach verschiedenen Verfahren und mit verschiedenen Zusatzmitteln sowie die Verwertung von Fischsilagen durch Mast-schweine mit besonderer Berücksichtigung der Schlachtqualität. [Preparation of fish silage by different processes and with different additions and utilisation of fish silage by fattening pigs with special reference to carcass quality.] *Arch. Tierernährung*, 1954, 4, 34-70. [Inst. Tierzucht., Univ. Kiel.]

The history of fish silage is briefly reviewed. Experimental silage was made in 14-litre jars with fish or fish refuse and the following amounts per 10 kg. fish were found to be minima: crude formic acid (85 per cent.) 154 ml., sulphuric acid (sp. gr. 1.84) 162 ml., molasses 500 g. with sulphuric acid 125 ml., and aureomycin 0.4 g. with formic acid 100 ml. Fine subdivision of the fish, to pass a 7-mm. sieve, gave improved quality with less acid. The storage temperature should be low. If the silage is to be used for foxes, the fish should first be steamed.

With sulphuric acid the pH of the silage may be as low as 2.8 and it should be neutralised with chalk. A.I.V. solution has the same disadvantage and is not recommended. Aureomycin alone is unsuitable on account of the growth of mould.

Feeding experiments were made with young pigs given fish silage with some cereals, and potatoes and beet to appetite, or fish silage with cereals to appetite; controls had fishmeal instead of silage. The first lot had commercial silage chiefly of herring refuse, and the pork and bacon tasted of fish even when the silage was left off 4 to 6 weeks before slaughter. The second was half of herring and mackerel waste and half of cod. There was no taste of fish. A white-fish silage was compared with white-fish meal and frozen white fish. The frozen fish was much too expensive and the silage was more expensive than fishmeal. The last experiment was with the amount of protein greatly reduced, to reduce the cost of pork. Rates of weight gain were not satisfactory.

A warning is added that herring refuse must not be used, unless it be for young stock or sows.

I. Leitch.

KRÜGER, L. and HINRICHSSEN, J. K. Versuche zur Frage der Eiweissgaben, Eiweissformen und Ergänzungstoffe in der Schweinemast. [Experiments on levels of protein, types of protein and supplementary substances in pig fattening.] *Züchtungskunde*, 1954, 25, 141-150; 26, 13-35. [Inst. Tierzucht, Justus-Liebig-Hochsch., Giessen.]

Fattening trials with groups of 3 or 4 Veredeltes Landschwein or cross pigs, 390 in all, at Oberer

Hardthof between 1949 and 1953 are reported. Full details of the rations are given. The results were analysed statistically and are given in tables.

The first report covers 6 trials on basal rations of potatoes and sugar or high-sugar fodder beet, with different mixtures of cereals and fishmeal or other protein, and minerals. In the first 3 trials, the effects of halving the percentage of total protein which was of animal origin, generally by substituting soya grits for some of the fishmeal, or of omitting animal protein altogether, were tested. Complete omission gave poor weight gains and feed utilisation, but in trial 3 the group with 16 per cent. of the protein of animal origin did almost as well as that with 32 per cent. animal protein. In the last 3 trials different proteins were tested against fishmeal. Dried whey, equal parts of dried whey and dried buttermilk, or whey protein gave results comparable with those of fishmeal; the concentrate mixture included alfalfa meal to make up for the low vitamin A content of the milk residues. The general conclusions were that for safety animal protein should form from 30 to 35 per cent. of the total protein and that success in fattening depends on the proper balancing of the ration.

The second report covers 13 trials with rations based on cereals, potatoes and beet, or a mixture of these, in which vitamin B₁₂ by mouth or by injection, or fish solubles, or preparations containing vitamin B₁₂ and aureomycin, penicillin or terramycin, were given along with full or restricted rations, or with rations containing restricted amounts of animal protein or none. The results are summarised in 2 pages of diagrams as well as in tables. Among the findings were the following. Restriction of total feed to 80 per cent. of that freely consumed was economically advantageous. Vitamin B₁₂ alone was without effect. Fish solubles, 3 per cent., improved a potato-beet ration with 27 per cent. of the protein of animal origin so as to equal one with 46 per cent. animal protein. Similar results were obtained with combinations of vitamin B₁₂ and antibiotics; 20 mg. antibiotic plus 20 µg. vitamin B₁₂ per pig daily sufficed. There was no advantage in adding these supplements to rations high in animal protein; if animal protein exceeded 40 g. and total protein 200 g. daily, rate of gain and feed utilisation were determined by the basis of the ration and cereals were superior to potatoes and beet. There were slight breed differences in responses to the supplements.—W. M. Deans.

FÉVRIER, R. Valeur alimentaire des levures. 2. Influence du mode de séchage de quelques levures de distillerie. [Food value of yeasts. 2. Effect of method of drying of some distiller's yeasts.] *Ann. Zootech.*, 1954, 3, 219-221. [Stat. Recherches Élevage, Jouy-en-Josas (S.-et-O.).]

The first paper was by Ferrier *et al.* (*Ann. Zootech.*, 1952, 1, No. 4, 1-10), and described the technique.

In the second experiment the pigs received 8 to 9 per cent. yeast, providing the same proportion of the N in each ration. Five yeast samples were compared. A molasses yeast dried at high temperature gave the best growth for the lowest feed consumption. Considerable differences in the riboflavin and vitamin PP contents of the yeasts were not reflected in the growth of the pigs.

SEIDLER, S. Zastosowanie siana w tuczu mięsnym. [The use of hay in fattening pigs for bacon.] *Rocz. Nauk rol.* [B], 1954, 87, 411-433. [Inst. Zootech., Oddział Doświad. Żywni.] Russian and English summaries.

Sixty pigs were given a ration of skimmed milk, cereal and steamed potatoes. They were divided into 3 groups and given supplements of hay, 150 to 250, 200 to 500 or 300 to 700 g. daily. The hays were of 5 kinds, meadow, clover and alfalfa, and clover and alfalfa dried mechanically. Average daily increase in weight exceeded 500 g. in all groups and carcass analyses showed no difference between them. The average amounts of feeds consumed by the groups were: potatoes 238-57, 247-78 and 308-52 kg.; concentrates 149-97, 111-03 and 105-88 kg.; milk 230-07, 204-86 and 226-64 litres; hay 21-42, 34-53 and 51-80 kg., respectively. The data for the 2 higher rates showed that by giving hay and increasing the amount of potatoes, savings could be made in concentrates and milk. (From summary.)

BIELIŃSKI, K. Zastosowanie suszu z cykorii w żywieniu bekonowym trzody chlewnej. [The use of dehydrated chicory in the fattening of pigs for bacon.] *Rocz. Nauk rol.* [B], 1954, 87, 435-448. [Inst. Zootech., Zakł. Doświad. Kółka Wielka.] Russian and English summaries.

Three groups each of 8 pigs were used. First a control group got a concentrate mixture containing from 34 to 38 per cent. potato flakes; for the second dried chicory formed 17 per cent. of the mixture and replaced half of the potato flakes; the third got no potato flakes and chicory constituted from 25 to 29 per cent. of the mixture. Average daily gains in weight for the groups were 729, 724 and 702 g., respectively, between which differences were not statistically significant. The amounts of digestible protein eaten per kg. weight gain were 468, 505 and 480 g. At slaughter no difference was found between the groups in carcass length, proportion of fat to lean, loin fatness or fat thickness.

The findings are of importance in view of the higher yield obtained per hectare from chicory than from potatoes. (From summary.)

FOWLER, S. H. and ROBERTSON, G. L. Some effects of source of protein and an antibiotic on reproductive performance in gilts. *J. Animal Sci.*, 1954, 13, 949-954. [Dept. Animal Husb., Texas Agric. Exp. Stat., College Station.]

Four groups, each of five 3-month-old gilts, were self-fed on a ration of milo, ground limestone, salt and vitamin B₁₂ supplemented with either animal- and vegetable-protein feeds, or animal- and vegetable-protein feeds plus chloromycetin mycelial meal, or vegetable-protein feeds, or vegetable-protein feeds plus chloromycetin mycelial meal. All grazed on Sudan pasture at night. The gilts were served at their second oestrus and were slaughtered 25 days after breeding.

Gilts fed on animal-protein foodstuffs reached puberty 16-9 days earlier than those on vegetable proteins only. This difference was statistically significant. Gilts receiving chloromycetin reached puberty 3-9 days earlier than those receiving no antibiotic, but this difference was not significant. There was an indication that antibiotic had a greater effect in advancing puberty in the vegetable protein groups, but this interaction was not significant.

Gilts receiving animal protein shed on an average 0-9 more ova at second heat than those receiving vegetable protein, but the difference was not significant. The difference caused by the antibiotic was even smaller and not significant.

There were advantages of 0-5 in number of normal embryos in favour of animal protein as compared with vegetable protein, and 0-6 in favour of chloromycetin as compared with no antibiotic, but these differences were not significant.

There was little difference between sources of protein in the percentage of ova shed which resulted in normal embryos, but there was an

advantage of 12.5 per cent. in favour of gilts receiving chloromycetin. This difference was not significant but suggested a favourable effect of antibiotic.

There was no apparent detrimental effect of chloromycetin on the Hb values of gilts.

2978

HORVATH, D. J. and VANDER NOOT, G. W. Effect of three levels of a new antibiotic, tetracycline, in a swine ration. *J. Animal Sci.*, 1954, 13, 899-903. [New Jersey Agric. Exp. Stat., New Brunswick.]

Five groups each of 6 pigs were fed from weaning to slaughter at between 199 and 207 lb. average liveweight. The basal diet, given to the control group 1, was of maize, barley, soya bean oilmeal, meat scraps, alfalfa meal and mineral and vitamin supplements. Groups 2, 3 and 4 received the basal diet supplemented with 10.85, 15.03 and 19.21 g. tetracycline per ton, respectively. Group 6 received the basal diet supplemented with 18 g. chlortetracycline and 18 mg. vitamin B₁₂ per ton.

From about 45 to 100 lb. liveweight diets containing 15 g. tetracycline and 18 g. chlortetracycline resulted in a 3.3 per cent. increase in rate of gain over the controls. From 100 to 200 lb. liveweight group 3 pigs grew slightly faster than other groups receiving antibiotic, but 3 per cent. slower than the controls. Over the whole experimental period the fastest growth was by the controls, group 1. No difference in growth rate was significant at the 5 per cent. level.

For feed per lb. gain groups 1 and 6 were similar before 100 lb. liveweight, but supplementation with 15 g. tetracycline per ton of feed improved efficiency by 31 per cent. over the controls. From 100 to 200 lb. liveweight this level of tetracycline again promoted the most efficient growth, 5 per cent. better than the controls and 9 per cent. better than the chlortetracycline group. Over the whole experimental period 15 g. tetracycline per ton of feed promoted the most efficient growth, 6 per cent. better than the group given 19 g., 11 per cent. better than the controls, and 14 per cent. better than the chlortetracycline group.

It is suggested that the relatively rapid gains and lack of scouring in all groups indicated adequate nutrition and good health and precluded to some degree the possibility of stimulation of growth by antibiotic.—I. A. M. Lucas.

2979

BRIDGES, J. H., HALE, F., KUNKEL, H. O. and LYMAN, C. M. The effects of bacitracin, penicillin and arsenic acid on growth rate and feed efficiency in swine. *J. Animal Sci.*, 1954, 13, 912-917. [Dept. Biochem. Nutrit., Texas Agric. Exp. Stat., College Station.]

Vol. 25, No. 2

Two experiments are reported, each on 6 groups of 7 pigs which were housed individually and self-fed from weaning to about 200 lb. liveweight. The basal diet, given to group 1 in both experiments, was of milo, soya bean oilmeal, alfalfa meal, and supplementary minerals and vitamins. In experiment 1 the supplements added to each ton of basal diet were: group 2, 10 g. bacitracin; group 3, 10 g. bacitracin and 2 g. penicillin; group 4, 1 oz. arsenic acid; group 5, 5 g. bacitracin and 1 oz. arsenic acid; group 6, 10 g. bacitracin and 1 oz. arsenic acid. The treatments were the same in experiment 2, except that the supplement for group 5 was 2 g. penicillin.

In neither experiment did any supplement result in significantly faster growth, although in experiment 1 the 3 groups receiving arsenic acid all grew 5 per cent. faster than the controls and group 3 grew 14 per cent. faster than the controls. In experiment 1 all groups receiving bacitracin took less feed per lb. gain than the controls, but these differences were not significant. In experiment 2, groups 3, 4 and 5 took significantly less feed per lb. gain than the controls, the saving in all groups being at least 6 per cent.

After slaughter, estimations were made of the arsenic content of liver, kidney and muscle of 2 pigs from each control group and from each group receiving arsenic.

The accumulation of arsenic was greatest in the liver, and reached on the average 5.2 p.p.m. in pigs from experiment 2. If arsenic was withdrawn from the diet for 5 days before slaughter, liver values did not exceed 1.0 p.p.m.

ROBINSON, K. L., COEY, W. E. and BURNETT, G. S. The use of antibiotics in the food of fattening pigs. *J. Sci. Food Agric.*, 1954, 5, 541-549. [Dept. Agric. Chem., Queen's Univ., Elmwood Av., Belfast.]

The results are summarised of several experiments made in Northern Ireland between 1951 and 1954. In these experiments growth responses to dietary antibiotics were small after 100 lb. liveweight, but there was usually a positive response before 100 lb. liveweight.

In the preliminary trials an all-vegetable diet and a diet containing fishmeal were given with and without 2 mg. procaine penicillin per lb. A feeding scale based on liveweight was followed, and although the antibiotic caused a 23 per cent. improvement in growth rate before 100 lb. liveweight on the all-vegetable diet and a 16 per cent. improvement on the fishmeal diet, it was thought that pigs on the vegetable-protein and animal-protein diets had been overfed and underfed, respectively.

The effects of scale of feeding on response to procaine penicillin were next examined. Before 100 lb. liveweight the growth response, as a percentage over the controls, was similar on 2 scales of feeding, although the low scale reduced the liveweight gains attainable. In this experiment the fishmeal diet was eaten more rapidly than the all-vegetable diet and the presence of dietary procaine penicillin increased the rapidity with which pigs ate both diets. When the ration was changed at 120 lb. liveweight and the pigs were deprived of both fishmeal and antibiotic there was a fall in appetite for a few weeks, but not if they were given either fishmeal or antibiotic.

In another experiment the removal of procaine penicillin from a fishmeal diet when the pigs reached 120 lb. liveweight caused a slight growth recession, but when Aurofac was removed from the diets of 2 pigs of this weight there was a marked growth check which was halted by the restoration of Aurofac to the diet. In this trial feed consumption during the first 4 weeks suggested that antibiotic stimulated growth more by inducing greater efficiency of feed utilisation than by increasing feed intake.

When pigs were self-fed on fishmeal diets dietary antibiotic did not stimulate appetite but the efficiency of feed utilisation was again better. When included in all-vegetable diets antibiotic did encourage increased food intake.

In one experiment there was no significant growth response to penicillin when included in a basal diet containing 10 per cent. fishmeal, but when 5 per cent. liver meal replaced half the fishmeal and when the basal ration was supplemented with vitamin B₁₂ there were positive growth responses to the antibiotic. These responses were not due to increased feed intakes.

When dietary procaine penicillin gave an early growth response but had little marked effect on overall growth rate it had no effect upon carcass quality, nor was there any effect on quality when Aurofac had produced a 30 per cent. response in overall weight gain.—I. A. M. Lucas.

2981

LASLEY, J. F., TRIBBLE, L. F. and HOGAN, A. G.
Value of antibiotics in swine rations. *Missouri Agric. Exp. Stat. Res. Bull. No. 543*, April 1954, pp. 55. [Columbia, Mo.]

The inclusion of antibiotics in maize and soya bean diets, supplemented with vitamins and minerals and self-fed in dry lot to weanling pigs until they reached 170 to 200 lb. weight, resulted in the following average percentage increases over the controls in growth rate and feed consumption per 100 lb. gain: aureomycin 17 and 9, procaine penicillin 10 and 3, chloromycetin 7 and 4, and streptomycin 5 and 7. The antibiotics were more

effective in stimulating growth rate during the early part of the feeding period, and smaller pigs responded more to antibiotic than heavier pigs, but it is suggested that this might be because smaller pigs are more susceptible to environmental conditions, and especially to infections.

Daily feed consumption was higher when antibiotics, other than streptomycin, were included in the diets, but this was probably due to the larger size of the pigs given antibiotic rather than to an increase in feed intake per unit of bodyweight.

When included in a maize and tankage ration, supplemented with minerals and vitamins, aureomycin resulted in increases in growth rate and feed conversion efficiency of only 3 and 6 per cent., respectively, while procaine penicillin resulted in no increase in growth rate but an 8 per cent. saving in feed.

When included in mineral- and vitamin-supplemented maize and soya bean diets, self-fed to pigs on pasture, the growth rate and feed conversion efficiency responses of 6 and 9 per cent., respectively, to aureomycin, and 0 and 6 per cent., respectively, to procaine penicillin in the diet were much less than when the diets were fed in dry lot. Also, when on pasture the antibiotic-fed pigs ate no more daily than the controls, unless they ate more forage.

In 2 experiments antibiotics were added to mineral- and vitamin-supplemented maize, soya bean and tankage diets containing either 18 or 12 per cent. crude protein. In the first experiment, when the pigs were scouring and unthrifty, the high-protein diet aggravated the scouring and the pigs on the low-protein diet grew faster. Aureomycin had the greatest beneficial effect when included in the high-protein diet. In the second experiment when there was no scouring, the situation was reversed, the high-protein diet being the better and aureomycin or procaine penicillin being more beneficial when added to the low-protein diet. Although pigs on the high-protein diet throughout the entire period of the experiment grew faster than others on the low-protein diet, feed conversion efficiency was better on the high-protein diet before 110 lb. liveweight and on the low-protein diet after 110 lb. liveweight.

HUTCHINSON, K. J. Further observations on the use of the Hammond system of pig carcass appraisal. *Queensland J. Agric. Sci.*, 1953, **10**, 207-213.
- Data were collected on body length, eye muscle thickness, backfat thickness and leg length of pigs from all Australian States, and regressions were calculated between these and carcass weights. There were differences between the regression coefficients calculated for the data from different States, but these were thought to be due partly to breed differences. In the appraisal of pig carcasses in Australia the corrections, used by Hammond, of scores based on certain carcass measurements for different carcass weights favour the lower carcass weight ranges. The data suggest that Hammond's "ideals" of backfat thickness in relation to weight need not be changed, but that in Australia his "ideals" for body length, thickness of eye muscle and leg length should be modified. The arguments for and against making these modifications are discussed.—I. A. M. Lucas.

BRAUDE, R., CLARKE, P. M. and MITCHELL, K. G. Analysis of the breeding records of a herd of pigs. *J. Agric. Sci.*, 1954, **45**, 19-27. [Nat. Inst. Res. Dairying, Univ. Reading.]
- An analysis of data from 487 Large White litters born between 1934 and 1950 is reported.
- For both gilts (first litter) and sows the mean gestation period was 114 days, and most litters were born between 112 and 116 days. However, the extreme range was from 109 to 120 days.
- The average number of pigs born per litter was 12.6 for sows and 10.3 for gilts; 6.4 per cent. of the pigs in sow's litters were born dead and 2.2 per cent. in gilt's litters. There was no significant effect of season on either numbers born or numbers born dead. Despite the production of more dead-born pigs, sows retained their advantage over gilts in number of pigs per litter born alive, 11.8 for sows and 10.0 for gilts. The lower mean figure for gilts was attributable in part to their lower maximum litter number of 15 pigs, the comparable figure for sows being 21. Sows still retained their advantage

even if it was assumed that pigs in excess of 14 per litter had to be destroyed because of limited number of teats.

The percentage of pigs born alive which died before 8 weeks was 31 for sows and 23 for gilts. Losses during the unfavourable winter farrowing season (September to February) were 35.9 per cent. for sows and 32.5 per cent. for gilts. These figures were higher than during the remainder of the year, when losses were 26.7 per cent. for sows and 19.4 per cent. for gilts. Of the overall losses 50 per cent. were due to crushing by the dam, even though nearly all farrowings were attended. Most of these pigs were crushed within 48 hr. after birth. Losses through crushing were greater in sow than in gilt litters, and more were crushed during the winter than during the summer months. The causes of the remaining 50 per cent. of deaths are tabulated also and discussed.

The higher losses in sow than in gilt litters resulted in average numbers weaned per litter of 8.1 for sows and 7.7 for gilts, a difference which was not significant at the 5 per cent. level. For sow litters a greater number of pigs were weaned per litter during the summer than during the winter, but there was no significant seasonal effect for gilt litters. There was no significant difference between the numbers of males and females weaned.

The mean weaning weights of male and female pigs were 30.3 lb. and 29.5 lb., respectively, and the mean weaning weights per pig of sow and gilt litters were 30.0 lb. and 27.8 lb., respectively. For both sow and gilt, pigs reared during the summer months were heavier at weaning than those reared during the winter. During the

summer sows and litters were kept in huts on pasture, but during inclement winter weather they were often kept indoors in a "Danish-type" piggery.

There was evidence that there was a progressive increase in numbers born, but not in numbers weaned, between a sow's first and fourth litter. There was also some indication that mean weaning weight increased with successive litters, but no definite conclusion on this could be drawn.

Wherever comparative figures are given above they were significantly different, unless otherwise stated.—I. A. M. Lucas.

2999

MARES, R. G. Animal husbandry, animal industry and animal disease in the Somaliland Protectorate. 1. *Brit. Vet. J.*, 1954, 110, 411-423.

The climatic and soil conditions of the 3 districts of Somaliland are described, with a brief sketch of the nomad Somali people. The most important domestic animal is the camel. Camel herds are grazed by the young unmarried men. Grazing has to be arranged in relation to the availability of salt, which is obtained from salt sand, salt plants or bought salt. Salt sand is eaten greedily by camels. The best salt plants are *Trianthema crystallina*, *Zygophyllum album* and species of *Suaeda* and *Salsola*. Camels grazed on the first 3 of these for 7 to 10 days get all the salt they need for a year. Other plants can supply enough salt for 2 months at a time. After salt grazing, camels must have water, unless there is very lush

pasture at hand. Camels acclimatised to living on the coast need a high intake of salt and frequent watering and cannot be used in high and cold districts. Customs concerned with the watering, breeding and working of camels are described.

Sheep are white with black heads and fat tails and goats are of the white Galla type. They are grazed near home by women and children. Salt is provided. Water is not needed when grass is green, but is provided about once a week in dry seasons.

Cattle are of Zebu type; there are few herds among the nomads, but they are commoner in the west, where they are crossed with Ankole cattle from Ethiopia and used for ploughing. They must be watered every second day at all seasons, so their grazing areas are limited. There is little horse breeding, and donkeys are used mainly in towns.—D. Duncan.

WEITS, J., HOUTMAN, A. C. and ROBORGH, J. R.
The effect of a iodinated casein fraction on the milk yield of goats. *Netherlands J. Agric. Sci.*, 1953, 1, 39-43. [Biol. Lab., N.V. Philips-Roxane, Weesp.]

This experiment was designed to test the hypothesis that iodinated casein might contain 2 hormones, a thyroxine fraction A affecting metabolism and a thyroxine-free fraction B having a lactogenic effect. The thyroxine fraction A was precipitated from the hydrolysed iodinated casein as a barium salt. Fraction B was precipitated in the residual solution by bringing the pH to 5.0 by the addition of HCl and acetic acid.

A group of 8 goats received intramuscular injections of from 0.3 to 0.5 g. of fraction B daily during the declining phase of lactation. Iodinated casein was given to a second group of 4 goats at rates of from 2 to 3 g. daily. The effect of both treatments on milk yield was judged by comparing the yield during treatment with the yield before and after treatment. Butterfat yield, liveweight, body temperature and heart rate were recorded.

Both treatments increased metabolic rate and milk and butterfat yields. All animals lost weight during treatment. The assumption that the B fraction contained only a lactogenic factor was considered invalid.—J. N. Aitken.

VORONOV, A. G. Osobennosti kormovogo ratsiona nekotorykh gryzunov. [Characters of the food rations of certain rodents.] *Zool. Zh.*, 1954, 33, 184-196. [Geograph. Fac., Moscow State Univ.]

An ecological study was made of 6 rodents classified according to their principal foods, which also determine the limits of their geographical

distribution. The rodents discussed were water rats, hamsters, house mice, wood mice, lemmings and voles.

Water rats showed a definite preference for more succulent foods. The moisture content of plants that were attractive to them varied between 67 and 87 per cent.; the parts of plants that were less eaten had a moisture content of less than 60 per cent. The food consisted of hygro- and hydrophytes.

The principal foods of voles were broad-leaved cereals and legumes. Green food rich in cellulose was the most important item.

Lemmings fed on narrow-leaved cereals and southern steppe grasses: *Poa*, *Festuca sulcata*, *Kochia* and *Artemisia*. The last was eaten much more in the autumn than in the spring and summer.

House mice preferred starchy seeds, green plants being a secondary food.

Wood mice, on the other hand, ate seeds, preferably oilseeds, Compositae, Rosaceae and green parts of plants.

Hamsters were omnivorous, food consisting of plants, seeds, fruits, small vertebrate animals, eggs and fledglings.

It is concluded that the kind of food eaten by these different animals is one of the main factors determining the distribution of rodents. The ecological optimum and ecological "centre of origin" are river valleys for water rats, southern steppes for lemmings, northern steppes for voles, broad-leaved woods for wood mice, northern steppes for house mice and forest-steppes for hamsters.—H. Scherbatoff.

1. Chicks of a Rhode Island Red—Light Sussex cross were reared to 10 weeks on either a high or a low plane of nutrition. In the former case they received to appetite a ration of dried milk 15, fishmeal 7, dried grass 5, linseed meal 3, middlings 20, maize 30, wheat 14, cod liver oil and minerals; and in the latter they received restricted quantities of a diet low in crude protein (13.9 per cent.) and made up of fishmeal 3, pea meal 9, dried grass 5, linseed meal 8, middlings 38, potato meal 23, maize 10, together with cod liver oil and minerals.
- At 10 weeks of age each group was again divided into a high and a low sub-group with rations generally similar to those used in the first stage. In this way 4 differently shaped growth curves were obtained from the individual sub-groups.
2. Sample birds were killed from each sub-group at intervals up to 24 weeks of age, and the carcasses dissected. Of the organs weighed only the eyes and heart were unaffected at each age by the different treatments used. The organs of the endocrine and reproductive system were the most affected. There were significant differences in the proportions even of birds of the same weight that had been reared in different ways.
3. Retardation of tissue growth in the low plane group in the first 10 weeks was almost completely made up in the growing period by the sub-group that was then transferred to a high plane of nutrition. Extensive data are reported for organ and bone weights according to age and treatment.

ASMUNDSON, V. S. and PUN, C. F. Growth of Bronze turkeys. *Poultry Sci.*, 1954, **33**, 981-986. [Dept. Poultry, Univ. California, Davis.]
- Data are reported from several hatches of 4 separate strains of Bronze turkeys. All the birds were reared alike and were weighed at 2, 4, 8, 12, 16, 20, 24 and 28 weeks of age. Rate of growth for each period was calculated from the formula
- $$\frac{100 (\log W_2 - \log W_1)}{t}$$
- where W_1 is the initial weight, W_2 the final weight and t the length of the period in weeks.
- Certain strains had faster growth rates than others to 8 weeks of age, with correspondingly slower growth afterwards. Rapid growth from 8 to 16 weeks was always followed by slower growth from 16 to 24 weeks of age. The correlations between percentage growth rates indicate that it may be possible with some strains to increase growth rate to 8 weeks of age with no effect on later growth.—M. J. Head.

MONSON, W. J., HARPER, E. A., BENTON, D. A. and ELVEHJEM, C. A. The effect of level of purified protein on the growth of chicks fed purified diets containing sucrose or dextrin. *J. Nutrition*, 1954, **53**, 563-573. [Dept. Biochem., Coll. Agric., Univ. Wisconsin, Madison.]

In a series of 8 trials chicks were fed from hatching to 4 weeks of age on a basal ration of alcohol-extracted casein 18, gelatine 10, soya bean oil 5, salts 6, L-cystine 0.5, fortified halibut liver oil, all the crystalline vitamins and sucrose to 100. These chicks finished with a general mean weight of about 330 g.; the mean in single trials ranged from 266 to 351 g. Parallel groups that received the same ration with dextrin in place of sucrose in 5 of the trials were about 30 g. heavier. This increase could be obtained also, though not with complete consistency, by increasing the casein content of the "sucrose" ration to 22 or 25 per cent. No further increase was obtained by increasing the protein content of the ration containing dextrin.

In further trials in which 2.5 mg. bacitracin and 10 mg. penicillin were added to each 100 g. of ration, 18 per cent. casein with sucrose gave as good growth as rations of higher protein content or containing dextrin. Growth on the basal

ration also was improved by the addition of 10 per cent. of either fibrin or wheat gluten.

In 2 chick growth trials the basal ration used consisted of "Drackett" protein 25, DL-methionine 0.4, ground cellulose 2, maize oil 3, minerals, vitamins, including folic acid and vitamin B₁₂, and cerelose to 100. After 1 week on the basal ration the chicks were allotted to experimental treatments. Those that continued to receive the unsupplemented ration in the 2 trials, which differed only in detail, finished with a mean weight of 370 g. at 32 days of age. Parallel groups receiving the same ration supplemented with 2 per cent. herringmeal and 5 per cent. "dehydrated green feed" were 15 per cent. heavier at this age.

There was no consistent growth stimulation in groups receiving either of these supplements alone. In a replication of one trial with the addition of ascorbic acid to all the rations no clear or consistent effect of this addition was seen.

JONES, H. L., COMBS, G. F. and ROMOSER, G. L. The presence of unidentified chick growth factor activity in dried whey prepared with a minimum of bacterial fermentation. *Poultry Sci.*, 1954, **33**, 930-932. [Dept. Poultry Husb., Univ. Maryland, College Park.]

In a chick growth trial the basal diet was of α -soya bean protein 23, L-arginine hydrochloride 0.2, L-cystine 1.0, L-leucine 0.15, DL-lysine hydrochloride 0.5, DL-methionine 0.4, DL-tryptophan 0.1, L-tyrosine 0.3, iodinated casein (containing 1 per cent. of thyroxine) 0.03, maize oil 3.0, minerals 6.0, all the known crystalline vitamins and sucrose to 100. Two groups, each of 14 chicks, that received this ration alone from 1 to 4 weeks of age had mean weight gains of 164 and 174 g., respectively. Three further groups that received this ration supplemented with 3, 6 and 9 per cent. of a

commercial dried whey product, containing 50 per cent. of lactose, gained 189, 193 and 185 g., respectively.

Further groups that received 3 and 6 per cent., respectively, of a special casein whey, prepared from pasteurised whole milk, after acid-precipitation of the casein, without opportunity for fermentation, gained 199 and 195 g.

It is concluded that the property possessed by commercial wheys of stimulating chick growth under these conditions is present in the original material and not the result of a fermentation process.—K. J. Carpenter.

CHARLET-LERY, G., DE BALZAC, H. and LEROY, A. M. Variation de la valeur alimentaire

des levures de distillerie suivant leur origine et leur mode de préparation. [Variation in feeding value of distiller's yeasts according to origin and method of preparation.] *Ann. Zootech.*, 1954, **3**, 215-217. [Lab. Recherches Zootech., Inst. Nat. Agronom., Paris.]

Four samples of beet yeast differently processed, one of "vinasse" yeast and 2 grown on molasses were compared. Each was given to 25 chickens from hatching to 6 weeks of age in a ration containing yeast 7 and barley meal 7 parts and a commercial chick ration to 100.

The weight gain per kg. feed consumed was significantly greater on the 4 beet yeasts than on the other types, though the total N content of the yeasts did not differ significantly. There was some correlation ($r = +0.58 \pm 0.17$) between the amount of feed consumed per kg. weight gain and the K content of the yeast.—D. Duncan.

KRATZER, F. H., DAVIS, P. N., WILLIAMS, D. E. and MARSHALL, B. J. Factors influencing the

growth of chicks and poult fed rations containing rapeseed oil meal. *J. Nutrition*, 1954, **53**, 407-418. [Dept. Poultry Husb., Univ. California, Davis.]

In preliminary trials the growth of chicks was found to be only 80 to 90 per cent. that of control birds when from 10 to 30 per cent. of soya bean oilmeal was replaced by rapeseed oilmeal in a good starter ration. No improvement of growth was obtained when either a water-treated meal was used, or when 37 p.p.m. pyridoxine were added to the experimental rations.

In view of a reported goitrogenic effect of rapeseed oilmeals (Abst. 742, Vol. 18) a study was made of the effect of adding up to 300 mg. per kg. of "Protamone", a thyroid-active preparation, to a practical ration containing 30 per cent. of rapeseed oilmeal. These additions had no effect on the growth of chicks, but reduced their thyroid mass from 16 to approximately 7 mg. per 100 g. bodyweight. The addition of 50 mg. potassium iodide per kg. ration had no effect on thyroid weight.

In further chick trials on a purified ration (Abst. 3486, Vol. 17) in which rapeseed oilmeal was the sole source of protein, the mean percentage daily gain ranged from 4.7 to 6.5 compared with gains of 6.2 to 7.9 for control chicks receiving a standard mash. The addition of a supplement containing lysine, arginine, cystine and tryptophan to the experimental ration had a small, but inconsistent, growth-stimulating effect. It was concluded that rapeseed oilmeal is itself an adequate source of amino-acids for the growing chick.

Chicks receiving a ration of rapeseed oilmeal 26, fishmeal 2.5, dried whey 2, alfalfa meal 2.5, wheat bran 5, aureomycin, mineral and vitamin supplements and cereals to 100 had a mean daily gain of 5.4 per cent. of their bodyweight. With a combined supplement of L-lysine 0.2, DL-methionine 0.1 and "Protamone" 0.01, the mean daily gain was 5.95 per cent. With only one or two of these additions the growth rate was intermediate between these values.

Poults receiving a similar basal ration, but with higher protein content, showed a mean daily gain in 22 days of 6.3 per cent. Other birds receiving this ration supplemented with 0.2 per cent. L-lysine had a daily gain of 6.7 per cent. The further addition of methionine and "Protamone" had only a small effect on growth. Poults receiving a standard mash had a daily gain of 7.3 per cent. There was a high incidence of "white-barred" feathers in the birds receiving rapeseed oilmeal without added lysine.—K. J. Carpenter.

MILNE, F. N. J. The value of maize in poultry feeding. *Queensland Agric. J.*, 1954, 79, 113-118.

Experiments with day-old Australorp chicks showed that an all-mash starter ration containing up to 40 per cent. maize produced satisfactory weight gains up to 7 weeks of age. With rations containing a higher percentage, up to 70 per cent., the weight at 7 weeks was too low.

From 7 to 24 weeks of age up to 70 per cent. maize in an all-mash ration was satisfactory.

All-mash laying rations for pullets in their first year of egg production were satisfactory when they contained 55, 62.5 and 70 per cent. maize. For hens in their second year of production 62.5 per cent. maize was the maximum permissible for satisfactory production.

When 30 per cent. or more maize is included in the ration manganese sulphate must be added.

BEGIN, J. J., MACLAURY, D. W., RISNER, R. and INSKO, W. M. (Jr.) Breed, sex, and age variation among chicks in response to antibiotic supplementation. *Kentucky Agric. Exp. Stat. Bull.* No. 597, June 1953, pp. 12. [Lexington, Ky.]

A group of 220 meat-type chicks was reared on a ration of soya bean oilmeal 30, alfalfa meal 5, maize distiller's dried solubles 4, dried whey 2, condensed fish solubles 2, minerals 4, choline chloride, nicotinic acid, concentrates containing vitamins A, B₁₂ and D and riboflavin, and yellow maize meal to 100. At 10 weeks of age their mean bodyweight was 1220 g.

Further groups received the same ration with the following supplements (the corresponding finishing weights in g. are given in brackets): aureomycin, 22 p.p.m. (1306); 3-nitro-4-hydroxyphenylarsonic acid, 55 (1313); bacitracin, 22

(1278); penicillin, 22 (1265); terramycin, 22 (1294); aureomycin, 22, plus sulphaquinoxaline, 125 (1352). The control group used 3.11 g. feed per g. liveweight gain. For the supplemented groups the figures were 3.02, 2.98, 3.00, 2.96, 2.93 and 2.90, respectively. Each group was made up of both males and females, each from 2 breeds.

Detailed analysis of the results suggested that the relative potency of the antibiotic supplements in stimulating growth differed with both sex and breed of the birds and with the stage of growth. Mortality was less than 9 per cent. in every group.

3063

COMBS, G. F., ROMOSER, G. L. and BISHOP, R. W. Influence of arsenic acid on dietary requirement of chicks for certain unidentified growth factors. *J. Nutrition*, 1954, 53, 511-522. [Dept. Poultry Husb., Univ. Maryland, College Park.]

A group of 100 chicks was reared from hatching on a ration of soya bean oilmeal 32.5, lucerne meal 2.5, dried whey 2, butyl molasses fermentation solubles 1, minerals 3.1, DL-methionine 0.05, choline chloride, riboflavin, nicotinic acid, pantothenic acid, vitamins A, B₁₂ and D, nitrofurazone, procaine penicillin and yellow maize meal to 100. Their mean weight at 8 weeks of age was 942 g. and the mean of a further group receiving the same ration supplemented with 120 p.p.m. arsenic acid was 918 g.

Further groups that received the original ration supplemented with 2 to 7 per cent. of fishmeal or fish soluble products finished with mean weights ranging from 936 to 988 g. The same treatments with the addition of arsenic acid gave mean weights ranging from 977 to 1020 g.

In 2 further trials, using slightly modified basal rations, it was again found that although arsenic acid gave no growth stimulation in the absence of fish products, and fish products alone had only a small effect, the combination of the 2 had a significant growth-stimulating action. As an overall result from 3 trials, the addition of a mixed supplement of 90 p.p.m. arsenic acid and 2 per cent. condensed fish solubles increased the growth rate of chicks by 6 per cent. in their first 8 weeks of life, and improved the feed conversion efficiency by 4 per cent., although the basal rations used contained all the known nutrients at levels believed to be adequate for rapid growth.—K. J. Carpenter.

- MILNE, F. N. J. The effect of benzene hexachloride in poultry feed on meat and egg quality. *Queensland J. Agric. Sci.*, 1953, 10, 214-221. [Div. Animal Indust.]

Cockerels, 12 weeks of age, were divided into groups, housed on sawdust litter and fed on a good commercial mash without supplement (Group 1) or with supplements of a commercial form of benzene hexachloride (BHC) containing 12.5 per cent. of the active γ -isomer, contributing 5 p.p.m. (Group 2) and 25 p.p.m. (Group 3). Further groups (4 and 5) received supplements of a deodorised BHC preparation containing 99 per cent. of the isomer; this was sprayed on the feed so as again to contribute 5 and 25 p.p.m., respectively, of the γ -isomer.

Birds were slaughtered and cooked for tasting tests at frequent intervals after the fifth week of the trial. After 11 weeks the flesh of birds from group 2 was inedible, and by 13 weeks that of group 3 was definitely tainted, the subcutaneous fat being the most affected. No off-flavour was recorded for birds from groups 4 and 5 even after 24 weeks of the deodorised BHC.

Similar experimental treatments were given to 5 groups of laying pullets. After 20 weeks of the experiments off-flavours were found consistently in the eggs from each of the groups receiving BHC, when the groups receiving deodorised BHC were only beginning to show this effect; eggs from

groups 2 and 3 were tainted after only 6 to 8 weeks of receiving the commercial BHC.

It is concluded that BHC is not a suitable insecticide for use with grain destined for poultry feeding.—K. J. Carpenter.

Two groups of 60 hens were given a ration containing 15 per cent. fishmeal or 30 per cent. sunflower seed meal. Within each group there were 4 pens of birds to which no vitamin supplement, 1 per cent. yeast, 1 per cent. fish oil or both of these were given. The sunflower seed group had lower bodyweight and lower egg production, egg weight and hatchability. Differences in bodyweight and egg production were significant at the 5 per cent. level and those in egg weight at the 1 per cent. level. Hatchability was greater in eggs from the hens receiving fishmeal. (From summary.)—D. Harvey.

N.A. and R., April 1955

A standard laying ration with 2.5 per cent. crude cottonseed oil added was given to 10 laying hens housed in a battery. Eggs were examined fresh, after 3 months' and after 6 months' storage at 1° C. From microbiological analysis of the yolk and white for methionine, cystine and serine it is concluded that ovalbumin selectively migrated from the white to the yolk during storage.

SLINGER, S. J., MORPHET, A. M., HUNT, E. C. and PEPPER, W. F. Effect of penicillin and forage juice on reproduction and growth of turkeys. *Poultry Sci.*, 1954, 33, 944-951. [Dept. Poultry Husband., Ontario Agric. Coll., Guelph.]

Thirty Broad Breasted Bronze turkeys in their first year of egg production were divided into 3 pens, each with a tom, and given a ration of fishmeal 2.25, dried buttermilk 1.25, meatmeal 1, soya bean meal 7.5, grassmeal 2.5, minerals 2.75, vitamins A, D₃ and B₁₂, riboflavin and cereals (wheat, oats, maize and barley) to 100. Over 16 weeks 1600 eggs were set from these birds and 68 per cent. of the fertile eggs hatched.

Vol. 25, No. 2

Parallel groups of birds received similar treatment, but with dietary supplements of either 1.5 mg. per lb. of procaine penicillin or 5 per cent. of forage juice, or both. Hatchability with these treatments was 72.8, 70.0 and 75.3 per cent., respectively. The supplements did not appear to influence either egg production, about 42 per cent. over the trial, or the number of infertile eggs, about 13 per cent. of the eggs laid. Daily feed consumption was 0.59 lb. in the control groups, and for the birds receiving the supplements 0.57, 0.60 and 0.57 lb., respectively.

Poulters hatched from the breeding trial were then used in a growth experiment for which the basal diet was fishmeal 2, dried buttermilk 2, meatmeal 2, soya bean meal 43, soya bean oil 1, minerals 4, DL-methionine, vitamins A, D₃ and B₁₂, riboflavin, nicotinic acid and cereals (wheat, maize and oat groats) to 100. At 32 days of age poulters receiving this ration unsupplemented had a mean weight of 600 g. Further analysis according to the diet of their dams showed means of 604 g. for the progeny of unsupplemented dams, and 579, 583 and 630 g. for the progeny of dams that had received penicillin, forage juice and penicillin plus forage juice, respectively. Other poulters that received their ration supplemented with both penicillin and forage juice at the same level as in the breeding rations had a mean weight at 32 days of 750 g. Further analysis of this figure, according to the diet of their dams, as above, showed means of 729, 767, 732 and 767 g. for the progeny of control and supplemented dams, respectively. In other groups poulters receiving either penicillin or forage juice alone grew at a rate intermediate between that of the control poulters and that of those receiving both supplements. It is concluded that, with the type of basal rations used, both penicillin and forage juice are of value in improving breeding performance and the growth of the young; but that for the latter the supplement received by the poult is of more importance than that included in the ration of the dam.—K. J. Carpenter.

3081

SHERWOOD, D. H. and MILBY, T. T. Further tests with antibiotics for laying and breeding hens. *Poultry Sci.*, 1954, 33, 1031-1033. [Larro Res. Farm, Detroit, Mich.]

In a series of 6 laying trials under different systems of management and with a variety of practical rations the overall mean production from 750 birds, on a hen-day basis, was 54 per cent. The mean production from parallel groups receiving similar rations with the addition of one or more antibiotics was also 54 per cent. The use of antibiotics was without effect on mortality, efficiency of feed conversion or hatchability of fertile eggs. Both light and heavy birds were

used, and the supplements, with their concentrations in the total ration in mg. per lb., were terramycin (5), aureomycin hydrochloride (6 and 50), terramycin and aureomycin mixed (11 and 18), and penicillin (2). In no case did a particular combination of feed, management and supplement give evidence of any response to the use of an antibiotic.—K. J. Carpenter.

KARAPETYAN, S. K. Vliyaniye udlinennoi svetovoi ekspozitsii na prodlenie biologicheskoi i produktivnoi zhizni domashnikh ptits. [Influence of lengthening exposure to light on prolongation of biological and productive life of domestic birds.] *Dokl. Akad. Nauk SSSR*, 1954, 94, 585-588. [Inst. Animal Husb., Minist. Agric., Armenian SSR.]

In this experiment 30 laying hens, 15 native and 15 Leghorns, were used. Each group was divided into sub-groups, an experimental and a control. During the first 2 years they were all kept under natural light conditions. From the third year onwards the experimental sub-groups had supplementary (artificial) lighting, with a continuous light-day of 16 hr. for 4 years, while the control groups were kept under ordinary

lighting conditions. Feeding and all the other conditions were the same for all groups.

With longer light the hens were more lively, had a higher physiological activity and laid more eggs than the controls. There were $2\frac{1}{2}$ times more Leghorn hens laying in the fifth year in the experimental than in the control group. The effect of prolonged lighting on the native hens was even more pronounced. All 7 hens in the experimental group were laying in the fifth year, 2 laid into the sixth year and one into the seventh year. Of the control native hens only 4 out of 8 were laying in the fifth year and none later.

During the 6 years the experimental Leghorns laid 56.5 per cent. more eggs than the controls, and the native experimental hens 92 per cent. more than their controls.—H. Scherbatoff.

SKALLER, F., ALLEN, T. E. and SHELDON, B. L.
The effect of intensity of daylight on egg pro-

duction of fowls in cages. *Austral. J. Agric. Res.*, 1954, 5, 578-583. [Div. Animal Health Prod., C.S.I.R.O., Poultry Res. Centre, Werribee, Victoria.]

The intensity of the light on individual birds in a normal battery house varies greatly according to their position relative to the source of light. An experiment was made to see if this had any effect on egg production.

Single Comb White Leghorn, Black Australorp and crossbred pullets were used. The intensity of light on the best and worst positions in the house was measured at 9.30 a.m. and 4.30 p.m. on at least 3 days each week of the laying year. It varied from 170 ft.-candles at 9.30 a.m. to 16 ft.-candles at 4.30 p.m. in the best lighted cages, i.e., those nearest the window, and from 11 to 1 ft.-candle for the worst lighted. Egg production of all birds was recorded. There was no significant difference between groups in the best and worst lighted cages.

3099

HEGGDAL, R. Norsk jordbruksproduksjon i nytt lys. [Norwegian agricultural production in new light.] *Tidsskr. norske Lundbruk*, 1954, 61, 306-316.

This is a lecture in which the changes in food production in Norway between 1939 and 1953 are summed up as follows: on a smaller area, with 170,000 fewer milk cows, with less imported concentrates and with about 22 per cent. less labour, plant and animal production has been increased by about 8 per cent. [It does not say how measured.] The population in the same time increased by about 15 per cent. The aim is to improve production still further and to regulate it so as to make the best adjustment to the Norwegian, Scandinavian, or possibly European markets. Details of production of individual

foods and groups of foods are discussed in relation to price, cost of production and habit. Policy must be defined, not in general terms but in terms of produce and in relation to subsidies.—I. Leitch.

3100

EHRICH, C. Welche tierärztlichen Leistungen tragen am meisten zur Steigerung der Erzeugung bei? [What veterinary measures contribute most to increase production?] *Berl. Münch. tierärztl. Wochenschr.*, 1954, 67, 306-308. [Münster.] English summary.

About 90 per cent. of Western Germany's meat requirements are met by home production. Pig meat amounts to 56 per cent. of total meat consumption, beef and veal to 34 per cent. About 38 per cent. of the total fat consumed comes from home animals. Further, 2,713,300 metric tons of liquid milk were produced and consumed during 1953. These figures indicate the importance of the veterinary expert's task of maintaining the health of the cattle and pig population. Prevention of animal diseases, advice on proper feeding to this end, and measures to prolong the useful life of cows (national average only $6\frac{1}{2}$ years) and to combat infertility and diseases of the udder are among their most important duties.—W. M. Deans.

3101

KRÜGER, L. Tierhaltung und Futtermittelbedarf in den Westzonen. [Animal husbandry and

fodder requirements in the West Zones.]
Schriftenreihe zur Fütterungslehre, No. 2,
pp. 34. [Giessen.]

This is No. 2 of a series of pamphlets on animal feeding, produced by the feedingstuffs manufacturers' association of Western Germany. It begins with a review of the position of agriculture before the war, with post-war comparisons. By the loss of the area east of the Oder Germany lost 25 to 30 per cent. of the acreage normally under cereals, potatoes and sugar. Part of this went to supply Berlin and the west. The population of the West Zones, compared with 1937, has increased by over 20 per cent. Per head of the present population the total food crop area has fallen by one-quarter, arable area by one-third and cereal and root areas by one-half. As a result, about 30 per cent. of food is imported.

The food and feedingstuffs positions, actual, potential and desirable, are discussed in detail in relation to purchasing power abroad, and the most economic use of feedingstuffs, with a plea for the benefits, especially in small-animal production and on small and medium sized farms, of ready-mixed feeds. There are 17 pages of tables and charts of pre-war and post-war production, targets for production and illustrative prepared feedingstuffs.—I. Leitch.

3102

HOPPE, A. Untersuchungen über Aufwand und Ertrag im Futterbau und in der Milcherzeugung des Oberen Hardthofes. [Studies of costs and returns in fodder production and in milk production on the Oberer Hardthof.] Inst. Tierzucht Milchwirtschaft, Justus-Liebig-Hochsch., Giessen, 1954, pp. 82 + 17 tables.

The first 18 pages of this report deal with standards for the feeding of dairy cows and the feed efficiency of cows in relation to milk yield and length of life in the dairy herd. Thereafter the farm, which is the experiment farm of the college, is described in detail, with charts of rainfall and temperature and a full account of cropping and crop yields for the small dairy herd for a complete year. The use of the crops is described and the state of health and production of the cows. Comparisons are made with statistics for the district of Hesse.

Conclusions include that the most generally useful and profitable sort of cow is one that gives 25 to 30 kg. milk daily with a flat lactation curve. In terms of yield of starch equivalent per unit area, most fodder plants surpass cereals and many equal or exceed potatoes. Fodder beet and other roots are valuable, especially when cows must be fed in stalls in summer. Green lucerne, and green maize, a most valuable carbohydrate-rich crop, are strongly recommended. Fodder crops provide

adequate or excess protein even for high milk yields; the danger in producing milk on fodder crops alone is of lack of starch equivalent.

I. Leitch.

3103

KRÜGER, L. Erzeugungskosten und Arbeitslöhne im Milchviehstall. [Costs of production and wages in the dairy stall.] Mitt. deutsch. Landwirts.-Gesellsch., 1952, No. 21, pp. 4. [Inst. Tierzucht Milchwirtschaft, Justus-Liebig-Hochsch., Giessen.]

In the author's view, small and medium farms in Germany are overstocked with cows by at least 10 per cent. and milk yields are uneconomically low. Better feeding of fewer animals would be more profitable, and additional liquid milk should be saleable seeing that the yearly milk consumption per head in Germany is only 64 kg., compared with 88 kg. before the war, and 180 kg. in the United States apart from that used in ice-cream.

The mean costs, other than feed, of producing milk are estimated at 21, 14, 10.5 and 8.4 Pfg. per kg. for annual yields of 2000, 3000, 4000 and 5000 kg. per cow, and the total costs at from 37 to 44, 26 to 31.5, 21 to 26 and 19 to 23 Pfg. according to the cropping system and the availability of pasture. With an annual yield of 3000 kg. per cow the farmer receives per hour's work in the dairy stall 0.69 DM. if the milk sells at 27 Pfg. (with return of skimmed milk) and only 0.30 DM. if the selling price is 24 Pfg. Paid labour at 1.25 to 1.40 DM. per hr. is economic only at a price of 26 to 27 Pfg. and with yields of 4000 to 5000 kg., or 3000 to 4000 kg. in regions with good pasture (average yield for Western Germany in 1951 was 2500 kg.).

These figures are borne out by a more detailed inquiry in January 1952 covering 230 farms in Hesse with 1580 cows and a mean annual yield of 3600 kg. milk; total costs, including 1 DM. per hr. for field work and 1.15 DM. for stall work, were from 23 to 37, mean 28 Pfg. or where there was summer grazing 21 to 28, mean 25 Pfg. Some data from other parts of Germany are also given.

W. M. Deans.

3104

BONADONNA, T. Considerazioni sulle specie e sulle razze di animali domestici produttrici di carne e sulle regioni di allevamento. [Species and breeds of domestic animals that produce meat and the regions in which they are bred.] Zootec. Vet., 1954, 9, 278-292. [Ist. Sper. Ital. "L. Spallanzani", Milan.]

The importance of a diet both balanced and palatable is stressed, with special reference to Italian cooking. Animal production is the basis of Italian agriculture and her greatest industry,

N.A. and R., April 1955

but the production of meat is insufficient. The highest proportion is of beef, followed by pork, poultry, mutton (including goatflesh) and horseflesh. In 1953 about 24.2 per cent. of meat supplies was imported; in 1952 livestock and meat represented 2.7 per cent. of the total value of imports, and meat products represented 15 to 20 per cent. of total exports.

It is urgently necessary to raise the standard of living in Italy, which has the lowest food consumption of any country in Europe, 2400 Cal. against 2510 for Greece. The average yearly meat consumption of 17 kg. per head is the second lowest in Europe, that of fats, 10 kg., the lowest, that of liquid milk, 49 kg., the second lowest, and cereal consumption, 157 kg. per head, the highest.

Tastes in meat differ from one country to another and even from one district to another. Fat joints are preferred in much of Italy; in Lombardy milk-fed veal is esteemed, and in Central and South Italy more lamb is consumed. Breeds of stock are compared according to their value in different conditions. Specialised beef breeds are not suited to the Italian economy. Pigs go mostly for the making of sausages and other prepared products and little fresh pork is eaten. Poultry production is mostly domestic and there is little industrial organisation. The distribution of livestock by species and age in the different regions of Italy is tabulated, and the total meat production per head of population in each province.—D. Duncan.

3105

PATUELLI, C. and SIGNANI, F. Costo di produzione del vitellone da carne romagnolo. [The cost of producing fat Romagnola calves.] *Riv. Zootec.*, 1954, 27, 332-333.

A balance sheet indicates that the cost of producing a fat calf weighing 490 kg. at 20 months is 188,704 lire, and the net cost per kg. meat is 340 lire. The cost to the consumer is between 450 and 1000 lire and the reason for this is again shown in a balance sheet. It is concluded that earlier maturing animals of greater liveweight should be the aim of breeders of Romagnola cattle, as well as greater milk production.—D. Duncan.

3106

CAMBRIDGE UNIVERSITY SCHOOL OF AGRICULTURE, FARM ECONOMICS BRANCH. Profitable egg production. *Farmers' Bull.* No. 17, October 1954, pp. 24. Price 2s. 6d.

Now, more than ever before, prosperity in the poultry industry depends on efficiency of egg production. The trend of egg prices is discussed as an introduction to a general discussion on profitable management under existing conditions,

Vol. 25, No. 2

and suggestions are made on the best policy and methods to be adopted.

Hatching dates should be carefully selected and good laying stock chosen. While avoiding heavy capital expenditure on specialised equipment, the most productive system of accommodation should be chosen. Production costs should be minimised by paying attention first to the major items of feedingstuffs and depreciation, and ways of doing this without reducing production itself are described.—T. D. Bell.

DINNIS, E. R. Grass production costs. Results from a grassland management investigation, 1951 and 1952. *J. Brit. Grassland Soc.*, 1954, 9, 183-193. [Imperial Chemical Industries, Ltd., Central Agric. Control.]

Detailed cost accounts were obtained for 54 mainly grassland dairying farms. One- and 2-year leys and other special purpose pastures based on single pasture species made up 75 per cent. of the ley area. The average annual fertiliser dressing per acre of the total farms' area was equivalent to 52 lb. N, 34 lb. P_2O_5 and 28 lb. K_2O and the removal of the war-time fertiliser subsidy was mainly responsible for the increase in grass production costs from £7.7 per acre in 1951 to £8.8 in 1952. The average yield of hay per acre per cut was 1.46 tons costing £6.6 per ton and of silage 4.29 tons costing £2.2 per ton. The cost per ton of starch equivalent in these 2 products was approximately the same, £17.3 to £19.2. This was twice the cost of grazed starch equivalent but only one-third that in purchased dairy cake.

KENDALL, K. A., HAYS, R. L. and ROLLER, G. D. Impaired reproduction in the rabbit fed supplemented diets containing soybean hay. *J. Animal Sci.*, 1954, 13, 859-866. [Dept. Dairy Sci., Univ. Illinois, Urbana.]

In 3 experiments the rabbits received a basal diet with percentage composition finely ground soya bean hay 49.5, ground wheat 49.5, NaCl 1. The poor fertility of females on this ration was not improved by supplements of *DL*-methionine, 0.3 per cent.; choline chloride, 0.3 per cent.; steamed bone meal, 1 per cent.; carotene; vitamin A; α -tocopherol; progesterone; 2-methyl-naphthoquinone; or vitamin B₁₂. Autoclaving the hay was also ineffective. Abortions and haemorrhages occurred in several groups.—D. Duncan.

3114

SCHÖNHERR, S. Sterilität bei Ziegen und ihre volkswirtschaftliche Bedeutung. [Sterility in goats and its economic importance.] *Berl. Münch. tierärztl. Wochenschr.*, 1954, 67, 311-313. [Tierklin., Freie Univ., Berlin.]

The goat population of Germany has fluctuated considerably, partly but not wholly in response to economic conditions. In 1939 there were over 3,200,000, and in 1949 still more, but since then the number has declined. In 1953, over 53½ million kg. milk was produced by about 910,000 goats. According to Machens (*Deutsch. Landwirtsch. Tierzucht*, 1933, 53, 1035) the value of goat's

milk, butter and meat, and meat from pigs reared on skimmed goat's milk, was over 343 million RM.

The most serious disease of goats is sterility in males, discussed in the remaining two-thirds of the article. [There is no suggestion of any nutritional cause.]—W. M. Deans.

Comparisons were made between interrupted periods of grazing on unrestricted pastures, interrupted grazing on restricted pastures, grazing for restricted times and normal rotational grazing. Only the third comparison, namely, restriction on a time basis, gave any protection against bloat. Long grass pastures proved to be less dangerous than short pastures. Cows tended to restrict their grazing periods voluntarily when the pasture was potentially dangerous: under these circumstances rumination times were also shorter. In

N.A. and R., April 1955

the early stages of bloat ruminal movements and belching increase in frequency and intensity. Atony occurs only in advanced stages.

NORDFELD, S., GELERSTEDT, N. and FALKMER, S. Studies on rape-seed meal and its goitrogenic effect on pigs. A nutritional and histopathological study. *Acta pathol. microbiol. scand.*, 1954, 35, 217-236. [Nat. Animal Exp. Stat., Upsala.]

Weanling pigs of the Swedish Landrace breed weighing 20 to 25 kg. were used. The basal ration was a mixture of oats 45, barley 45 and wheat bran 10 per cent. This ration was supplemented with different kinds of protein. In the control group skimmed milk was used and in the test groups rapeseed meal untreated or after extraction with hot water. Supplements of alfalfa, vitamin

D₃, CaCO₃, calcium phosphate and NaCl were given. Equal amounts of energy, protein, vitamins and minerals were supplied to the different test groups. The pigs were fed twice daily and weighed weekly. Antibiotics, vitamin B₁₂ and bacitracin were given to some groups and also an iodinated casein showing 2 per cent. of the activity of synthetic thyroxine.

Two experiments were made. In the first, the time necessary for the pigs to reach 100 kg. from a starting weight of 22.4 kg. was 125 days in the group on grain and skimmed milk; 127 days in the group on grain and rapeseed meal which was given at the levels of 13.0, 9.5 and 8.0 per cent. as the pigs reached a weight of 30, 40 and 50 kg.; 126 days in the group getting rapeseed meal and bacitracin; 125 days in the group getting bacitracin and vitamin B₁₂ and 125 days in a group getting soya bean oilmeal. Although daily growth rate was less in the group on rapeseed meal the difference was not statistically significant; the amount given was low and the meal was omitted after the pigs reached 75 kg.

In the second experiment both untreated and water-extracted rapeseed meal were tested. In groups not receiving wheat bran the percentage of rapeseed meal in the rations was 17.5, 10.0, 7.5 and 3.1 when the pigs weighed 30, 40 and 50 and 90 kg. The water-extracted meal had a significant effect on growth, and this effect was enhanced by the addition of 10 per cent. wheat bran. The addition of iodinated casein, 0.5 g. per 100 kg. bodyweight, did not affect growth, but reduced the thyroid enlargement caused by the unheated rapeseed meal. The water-extracted meal had no goitrogenic effect. The control group on skimmed milk reached 92 kg. in 106 days. The untreated rapeseed meal group took 131 days. The water-extracted rapeseed meal group took 123 days, but the addition of 10 per cent. wheat bran reduced this to 114 days. The untreated rapeseed meal at levels of 10 to 20 per cent. also increased the size of liver, kidney and thyroid. The addition of vitamin B₁₂ or bacitracin or both to these all-plant protein diets had no significant effect on growth under these experimental conditions.

GILL, J. C. and THOMSON, W. (with PARK, G. T.) The production of ketonaemia and pregnancy toxemia in ewes through manipulation of the feeding level. *J. Agric. Sci.*, 1954, 45, 229-240. [Rowett Res. Inst., Bucksburn, Aberdeenshire.]

Ewes were maintained on low and high planes of feeding throughout pregnancy; the high-plane ewes were checked by a sudden reduction of the food 7 weeks before lambing. Blood ketones were

estimated regularly in all animals. The trials extended over 2 years and involved 120 half-bred ewes.

Pregnancy toxemia occurred in only 2 ewes during the first season, one in the low-plane and one in the high-plane checked group. Eight ewes were affected in the second season, all in the high-plane checked group; 4 of these when the check in nutrition was imposed and the other 4 after a 48-hr. fast imposed 11 days before they were expected to lamb. A high concentration of ketone bodies in the blood was not always associated with pregnancy toxemia, and some ewes had high values for blood ketones without showing signs of the disease. It is concluded that ketonaemia is not responsible for the syndrome known as pregnancy toxemia. A check in the feeding is likely to produce ketonaemia, but the essential disturbance of pregnancy toxemia is more obscure.

BOHSTEDT, G. and GRUMMER, R. H. Salt poisoning of pigs. *J. Animal Sci.*, 1954, 13, 933-939. [Dept. Animal Husb., Univ. Wisconsin, Madison.]

Two groups, each of 6 pigs, were given a low-salt diet for 99 days. One group was full-fed and the second group was restricted to about 80 per cent. of full feeding. The trough space was limited in order to promote greed. On the 99th

N.A. and R., April 1955

day the full-fed group was given a wet feed containing 6 per cent. NaCl on an air-dry basis, each pig consuming about 2.4 oz. salt during that day. The second group was given a wet feed containing 8 per cent. NaCl on an air-dry basis, each pig consuming about 3.2 oz. salt. For the next feed, on the following afternoon, both groups were given a wet feed containing 8 per cent. NaCl on an air-dry basis, but they were reluctant to eat it all. On the third day the pigs were fed and watered normally, but several pigs were found lying paralysed and semi-conscious. By the fifth day only one pig remained in the full-fed group and 2 in the restricted group.

The paralysis and death were attributed to NaCl poisoning or to stress due to change of concentration of dietary NaCl. The only gross anatomical change observed was in the liver. Serum Na and Cl values were normal.

The conditions favouring NaCl poisoning are listed. They include preliminary salt starvation, greed, salt in amounts of 1.5 or 2.0 per cent. of the wet feed, no additional drinking water, and more than one feed of a high-salt diet.

PRIOUZEAU, M. Intoxications alimentaires à rentissement pulmonaire, chez les bovidés. [Nutritional intoxication with pulmonary consequences in cattle.] *Rec. Méd. vét.*, 1954, 130, 81-104. [Mareuil-sur-Lay, Vendée.]

A general account is given of the digestive and pulmonary signs, diagnosis, prognosis and treatment, of disturbances caused in cattle by eating too freely of certain plants not normally regarded as poisonous, or poisonous only at certain stages of growth. The plants thus considered are the leaves, stems and flower heads of fodder crucifers

of cabbage and mustard type, the water horseradish (*Roripa amphibia*), the wild cress (*Nasturtium sylvestre*), peppermint and thyme. Feeding on aftermath is considered especially dangerous. The nature of the substances causing the intoxication is briefly discussed.—E. M. Hume.

IMMUNITY

3146

SMITH, H. W. Food as a vehicle of infection: the effect of variations in the diet on the induction of *Salmonella gallinarum* infection. *Brit. J. Exp. Pathol.*, 1954, 35, 447-458. [Animal Health Trust, Houghton Grange, Huntingdon]. Groups of 9-week-old cockerels from a salmonella-free flock, individually housed and fed on a basal diet of whole wheat and the following mash: wheat meal 12.5, barley meal 12.0, oatmeal 16.0, pea meal 3, maize meal 15, middlings 15, maize gluten feed 5, grassmeal 7.5, minerals 1.25, synthetic vitamin D 0.25, white fish meal (66 per cent. protein) 10, dried yeast 2.5 per cent., were used to test the effect of a single dose of known

numbers of *Salmonella gallinarum* given in different feeds. From survivors after 3 weeks blood and rectal swabs were examined; the chickens were then killed and the carcasses examined for infection.

Preliminary experiments showed that the pH of gizzard contents was significantly higher in chickens fed on mash than in those fed on whole wheat or coarsely or finely ground wheat. Grinding, or addition of middlings to finely ground wheat, did not affect pH; addition of 10 or 15 per cent. fishmeal, but not of 10 per cent. casein, to wheat raised the pH value to that with mash.

Groups of chickens were given infected mash; whole wheat with or without 20 per cent. alkali (powdered chalk 40, colloidal kaolin 43, magnesium trisilicate 17 per cent.); the 3 wheats plus 15 per cent. fishmeal; finely or coarsely ground wheat alone; or finely ground wheat plus 20 per cent. middlings. The chickens were killed after 2, 4, 6, 8 and 24 hr. and counts were made of *Salm. gallinarum* in contents of gizzard, duodenum, ileum and rectum. *Salm. gallinarum* counts were zero or negligible in the gizzard of chickens fed on any of the wheats. Destruction of *Salm. gallinarum* was much less with mash or diets containing fishmeal, and was prevented by alkali. There was no appreciable destruction of *Salm. gallinarum* in organs beyond the gizzard. Further experiments *in vitro* and *in vivo* confirmed the relation between gizzard pH and destruction of *Salm. gallinarum* therein.

Of 92 chickens given 50×10^5 *Salm. gallinarum* in mash, 63 became infected and 31 of these died; with whole wheat only 11 and 4. Addition of 20 per cent. alkali to both diets raised the infection and death rates. In groups of 36 birds given the same dose in wheat whole, coarsely ground or finely ground the respective numbers infected were 4, 11 and 18; when 15 per cent. fishmeal was added, 29, 29 and 30. Addition of 20 per cent. middlings to finely ground wheat did not raise the infection rate.

Finally, 10 heavily infected chickens were added to each of 2 groups of 50 chickens housed in identical outdoor arks and one group was fed on mash only and the other on whole wheat only. After 6 weeks 23 mash-fed chickens were infected and 8 of these had died, but only 7 and 4 of the wheat-fed chickens. Hence it is suggested that when a natural outbreak occurs in a flock, it would be worth while to alter the diet to whole wheat only.

It is concluded that both the consistency of a feed and its capacity to neutralise gastric acidity affect the bactericidal action of the gastric juice in the gizzard. This may lead to erroneous conclusions from experiments on host nutrition and resistance to infection and it is suggested that in such experiments animals should be fasted for 12 to 18 hr. and then be given the infective dose in an alkaline medium.—W. M. Deans.

SPEDDING, C. R. W. Production of worm-free lambs at pasture. *Nature*, 1954, 174, 611. [Grassland Res. Inst., Hurley, Berks.]

Nine ewes and 15 newborn lambs were moved, every 2 days, on to a fresh area of newly sown ley on land which had been free of cattle and sheep for 2 years. Average egg count in ewes was 300 eggs per g. faeces but up to weaning was negligible in the lambs. A similar group of ewes and lambs followed the first over the pasture and the average count of these lambs was 90 eggs per g. Lambs on the worm-free pasture made quicker weight gains than those sub-clinically infected. It is believed that this is a truer comparison of the effect of worm burden than is possible in indoor trials where re-infection by grazing is not accounted for.—J. C. Gill.

7. BOOK REVIEWS

3151

CONNELL, V. (Ed.) **The application of results of research.** Butterworths Scientific Publ., London, 1954, pp. vii + 212. Price 21s.

This report was prepared at the request of the British Commonwealth Scientific Official Conference of 1946, presented to the 1952 Conference and at the request of that Conference extended to 1953. There is a short introduction and four short chapters outlining methods of conveying the results of research to those who have practical use for them. Conventional Methods include publication, abstracting services, press publicity, exhibitions, films, broadcasts and special developments of all these which are outlined under Special Methods and include agricultural extension services, the establishment and maintenance of standards, surveys of industry and liaison with industry. Among Obstacles to the Use of Information very rightly stands first the use of a "cryptic argot" thought to be "scientific", and second the difficulties of bridging the gap between discovery and factory.

There are Appendixes which outline chiefly the special methods used in the United Kingdom, Canada, Australia, New Zealand, South Africa, India, Ceylon and Southern Rhodesia, and finally "novel" methods in the United States, those chosen being the Tennessee Valley development, the Bureau of Agricultural and Industrial Chemistry of the U.S. Department of Agriculture with 4 Regional Laboratories that run demonstration pilot plants with local produce, and the Research Corporation and University Research Foundations.

This should be a useful guide in a general way. It might have been more useful overseas if addresses of at least the more important organisations had been given.—I. Leitch.

3152

GREENBERG, D. M. (Ed.) **Chemical pathways of metabolism.** Volume 2. Academic Press, Inc., New York, 1954, pp. viii + 383. Price 76s.

Considerable progress has been made in recent years in describing biosynthetic as distinct from degradative pathways of metabolism, mainly by the use of isotopic tracers and, to a less extent, biochemical mutants of micro-organisms. The previous volume, reviewed in Abst. 1546, Vol. 25, discussed non-nitrogenous compounds and their metabolism; this volume is concerned with nitrogenous substances.

A chapter on nitrogen metabolism of amino-acids by P. P. Cohen (pp. 46) is concerned more with the enzymes involved than with the biological significance of the reactions they catalyse, and

largely ignores those reactions where purified enzymes have not yet been obtained, which is a pity. Three chapters by Greenberg, on carbon catabolism of amino-acids (pp. 66), synthetic processes involving amino-acids (pp. 36) and the metabolism of sulphur-containing compounds (pp. 24) and a chapter on the enzymic synthesis of peptide bonds by H. Borsook (pp. 50) give a full account of the remainder of amino-acid metabolism, though omitting much of the recent speculation on mechanisms of protein synthesis.

M. P. Schulman discusses purines and pyrimidines (pp. 39), collecting some diverse information on their synthesis. Nucleotides and nucleosides are considered by L. A. Heppel (pp. 24) and the volume concludes with a description of the metabolism of haem and chlorophyll by S. Granick (pp. 56). There is an extensive bibliography, including a surprising number of papers dated well into 1954. Some of the chapters are followed by addenda reporting recent works, which are not included in the index.

Biochemically-minded nutritionists should look elsewhere for accounts of digestion, but they will find this book valuable for a clear, comprehensive and really up-to-date account of the synthetic and degradative reactions undergone by the products of digestion once they are absorbed. Biochemists will find the metabolism of micro-organisms and some of that of plants adequately discussed, particularly where the reactions concerned are shared with mammals.—C. Warner.

3153

ALBRITTON, E. C. (Ed.) **Standard values in nutrition and metabolism.** Wright Air Development Centre, Ohio, Tech. Rep. Nos. 52-301, December 1953, pp. xi + 380.

The Committee on the Handbook of Biological Data works in the United States of America under the American Institute of Biological Sciences and the National Research Council. The system under which this Technical Report has been produced was for the Committee to have the help, first of a number of contributors who prepared the material, and later of a number of reviewers who gave their comments. Seldom, outside the production of encyclopaedias, can a publication have had as many as the 800 collaborators who have played parts of varying degrees of importance in the preparation of this one. The aim was a corresponding weight of authority inherent in the information as presented.

Of its demy quarto pages 250 are taken up by the 13 Sections in which the 160 Tables are grouped and just over 100 pages are required for the

bibliography on which they are based. The values quoted can truly be said to be standards in nutrition and metabolism. Their variety can probably best be described by saying that something can be found about the needs of living organisms from the highest to the lowest orders, whether animal or vegetable in nature, multi- or unicellular in structure; something, too, can be found over the same range of species about pathways of metabolism and excretion of end products. Moreover, the arrangement of letters for designating columns and numbers for designating rows in the tables makes identification of an entry by 2 coordinates simple and the tracing of it in the bibliography need take only a few seconds. The diligence of those who have brought together so much information and arranged it so skillfully is indeed admirable. The principles that they have followed where ranges of values were available should ensure that the data are authoritative.—D. Harvey.

3154

ROWETT RESEARCH INSTITUTE. *Family diet and health in pre-war Britain. A dietary and clinical survey.* Carnegie U.K. Trust, Dunfermline, 1955, pp. 164.

In 1937 Lord Boyd Orr's hypothesis that much ill-health resulted from undernutrition consequent upon poverty was put to the test in a dietary and clinical survey which covered 1352 families in 16 districts of England and Scotland. It was a big and courageous enterprise which broke much new ground and gave rise to a lot of new thinking.

It is a pity that almost 20 years elapsed before the report was published, and Lord Boyd Orr himself tends to dismiss it in his preface as "mainly of historic interest". But this is misleading, because a part analysis and conclusions were passed to the Ministry of Food at the beginning of the war to form the basis of the country's food rationing programme and, as such, to father what remains the greatest and most successful feeding experiment of all time. Much of the thought behind the survey and many of the important conclusions which were based on the data in the report have already been recorded elsewhere (*e.g.*, *Abst.* 2946, Vol. 12 and Review Article, Vol. 24, p. 1).

Now that the meat has been distributed, only the skeleton remains for this report: the detail of the methods used, the tabulated results, the mathematical calculations; and Dr. D. Harvey is to be congratulated on his careful preparation of this immense quantity of data after the original survey team had dispersed. It is not easily digestible without more accompanying commentary and one is made too conscious, by the large proportion of space devoted to the description of methods, of the crudity of many of the tools available at the time. But if the detail is sometimes rough, the

picture is nevertheless very clear and it is sobering to look back only 18 years to see how high a proportion of people were eating less than they required to maintain their health while living in a country with one of the highest standards of living in the world.

There are a great many important lessons buried in the figures of this report, and for workers in the fields of human nutrition and sociology it will repay many hours of patient browsing. For those interested in child growth, there are the results of a large, and what must be unique, feeding experiment with children which is not published elsewhere. "Any investigation into modern conditions and relationships of food, health, and income would have much to learn from the Carnegie Survey by profiting not only from its mistakes but also from the boldness and simplicity of the concepts on which it was based."—F. E. Hytten.

3155

TROWELL, H. C., DAVIES, J. N. P. and DEAN, R. F. A. *Kwashiorkor.* Edward Arnold (Publishers), Ltd., London, 1954, pp. xii+308.

At the end of their description of the disease in children the authors of this book give a summary of their views. The 18 paragraphs which compose that summary are, according to the preface, the only part of the book which is the joint work of all 3 authors. Much consideration must have been given to its composition and, while only quotation in full would do justice to the authors' views, it seems that the first 2 paragraphs of that summary might safely be quoted apart from their context.

"1. Kwashiorkor is most frequently seen in children who have recently been weaned: that is, in children between the ages of 1 and 2 years.

"2. Lack of protein in the diet is probably an important cause. The lack may be due to poverty or to habits of growing and eating foods which supply adequate carbohydrate but little protein."

The first section of the book, on the history of the disease, is the work of the senior author, a specialist physician. Few diseases can have had so many different names, of which infantile pellagra, nutritional oedema, malignant malnutrition and multiple-deficiency dystrophy are some. Scarcely less numerous have been descriptions of the signs which appear in the skins of children with the disease: cracked skin, mosaic skin, crazy pavement dermatosis and enamel paint dermatosis. In adult life corresponding conditions may be called reptile skin or elephant skin. Misunderstanding has also arisen in connection with the English equivalents of the words in the Ga language from which the name kwashiorkor is

derived. It is now considered that *kwashi* means first and *orkor* second, a reference to the child being "deposed" by the next younger sibling and not to its having acquired a red colour in its hair or skin.

With polemics crowding the clinical literature, the unanimity which is reported by the second author as existing in the literature of its pathology makes more welcome reading. Fatty infiltration of the liver was an early finding in the histopathology; the facts that it is preceded by atrophy of the pancreas and accompanied by changes in enzyme-secreting cells throughout the body have been the particular contributions made by the second author.

The biochemical findings on which, more and more, final diagnoses seem likely to depend, and the system of treatment with preparations of skimmed milk or of vegetable foods rich in protein are described in detail in the section by the third author, a research worker.

The penultimate section deals with protein malnutrition in adults, and the book ends with a discussion of the implications for the general population of deficiencies of protein in the diets of children or adults.

The authors are under no illusion about the danger of attempting to explain too many of the differences between European and tropical populations as resulting from differences in the amounts of protein available to them. Their work has been centred at Mulago Hospital in Kampala. In the neighbouring territory of Kenya most reports of the disease have come from the Central Province where, as in Buganda, from which Mulago gets many of its patients, some form of banana is a common constituent of the diet. Between these two areas lies the Nyanza Province of Kenya where medical and hospital facilities are no scarcer, where bananas may be less abundant and whence reports of the disease are much less common. Frequently throughout the book there is mention of the need for further investigations. On the basis of the work reviewed it appears that field observations in some part of East Africa where the incidence of the disease is lower may provide replies to some of the questions that remain unanswered.—D. Harvey.

3156

VAN WERSCH, H. J. *Scurvy as a skeletal disease. A comparative study of scurvy and rickets, clinically, histologically, histochemically, biochemically and roentgenologically.* Dekker and Van de Vegt N.V., Utrecht, 1954, pp. xvi + 365. Price Fl. 28.50.

In many ways this is a remarkable book. The preface tells us that it is the work of a general practitioner and the autobiographical introduction describes its origin from, first, a study of calcium

and phosphorus metabolism in tetany for an M.D. thesis, and then the accident of having as patient a girl, aged 17 when first seen in 1935 with scurvy that had been diagnosed as sarcoma in 1931 and 1932. To the meticulous study of the girl at intervals over 12 years, add a brief history of scurvy and a quite extensive study of the bone histology and histochemistry of guinea-pigs, normal and scorbutic, and of rats, normal and with rickets, a chapter on man's requirement of vitamin C and a few odds and ends, and you have a very unusual book indeed.

The history of scurvy is brief. It does pick out the main highlights but makes no attempt to discuss the medical absurdities that flourished round the name scurvy, up to and even after the time of Lind. There are more recent items of considerable interest, such as the declaration by Benekamp and Hijmans Van den Bergh in 1899 that a diet of boiled milk gives a baby Barlow's disease because of the destruction of something in the milk, and the facsimile of the letter from Van den Bergh in which he says the fact was obvious if the mind could be diverted from bacteriology.

Part 2 of the book, one chapter of 17 pages, gives the astonishing history of the patient, who possibly had scurvy in infancy and certainly had it severely, with subperiosteal haemorrhage, from 1931 to 1935, and intermittently between 1936 and 1945, with 2 fractures that would not unite and more subperiosteal haemorrhage. Yet her vitamin C requirement as estimated by van Eekelen's method does not seem to have been abnormal and her blood ascorbic acid at saturation was normal. Certainly her diet was deficient; boiled milk in infancy, when first seen bread and butter, tea, coffee, chocolate and occasionally a very little fruit. There was great difficulty in getting her to take milk, cheese, fruit or vegetables and treatment had to be with ascorbic acid. There is throughout the history the further extraordinary fact that there is no mention of petechiae, swollen gums (although her teeth were yellow with white spots), or changes other than in the bones. The picture throughout suggests that of "infantile" scurvy. The question is inevitable whether perhaps more than one substance required for structure and repair was not lacking.

The view on vitamin C requirement is: although little is needed to prevent or cure scurvy, saturation is probably the best condition since it is that found in animals that synthesise their own.

The final chapter is on the effects of germination and of sunshine on the vitamin C content of plants.

The book is well produced and profusely illustrated with X-ray photographs and photomicrographs. On the whole, it is a most interesting medical document, such as is too seldom produced nowadays.—I. Leitch.

3157

BEEZIN, Ya. M. Znachenie solei kobal'ta i medi v kormlenii sel'skokhozyaistvennykh zhivotnykh. [Significance of the salts of cobalt and copper in the nutrition of domestic animals.] Acad. Sci. Latvian S.S.R., Zootech. and Zool. Inst., Riga, 1952, pp. 124.

This is a study of "sukhotka" which occurs on cobalt-deficient soils in Latvia. It is a disease resembling osteomalacia and "licking disease" and affects lambs and kids, sheep and goats, calves and adult cattle in that order, particularly pregnant animals and highly productive cows, but is rarer in pigs and horses. The signs are loss of appetite, constipation and dry skin, and in ruminants cessation of rumination. A map is included showing differences in intensity of the disease in Latvia. A review of Soviet and foreign literature seems to show that the signs of "pining", "coast disease" and "sukhotka" are similar.

In Latvia the worst affected animals were on soils with an available Co content of 1.5 to 2 mg. per kg. With a Co content of 2 to 2.3 mg. per kg. there was less sickness. On soils with a Co content of 2.3 to 2.5 mg. per kg. animals were free of the disease. Fertilisers and agricultural technique as well as the type of plant affected the amount of Co in plants. The soils with the highest Co content were turf-carbonate leached soils and heavy clay loams. Light podsolised and sandy soils, also boggy soils, had a low Co content.

Experiments with Co supplements were made with sheep, calves, cows, pigs and chickens and anatomical, histological, chemical and haematological investigations of the carcasses of the control animals not receiving Co, all of which died, were made.

Only brief mention is made of vitamin B₁₂, which is a complex containing about 4.5 per cent. Co.

Administration of Co to cattle, pigs and chickens increased Hb, and vitamins A, E and C and Fe in the organs were also increased.

Although copper is mentioned in the title of this paper not much reference is made to it in the text, the main emphasis being upon cobalt. Where soils lack Cu a combination of Cu and Co is recommended for ruminants with "sukhotka".

Prophylactic daily doses of cobaltous chloride are given as: cows and horses 10 to 20 mg., pigs, calves and foals 5 to 10 mg., sheep and goats 1.5 to 2.5 mg. Therapeutic doses, in the same order, are: 20 to 40 mg., 10 to 20 mg., 2.5 to 5 mg.

H. Scherbatoff.

BURLEW, J. S. (Ed.) *Algal culture from laboratory to pilot plant*. Carnegie Institution of Washington Publ. No. 600, 1953, pp. ix + 357.

This collective work is in the nature of a progress report. It consists largely of accounts of experiments on the culture of *Chlorella* spp. under the auspices of the Carnegie Institution of Washington and other bodies in the United States, but includes also accounts of some in the United Kingdom, Holland, Germany, Venezuela, Israel and Japan. Unfortunately, apart from the rather later Japanese work, the story is carried only to the end of 1951, by which time some 100 lb. of *Chlorella* had been grown in a transparent polyethylene plastic tube holding about 1000 gal. in a pilot plant at Cambridge, Massachusetts, and it was clear that the new "crop" had interesting possibilities but that many practical difficulties in the growing and harvesting of it had still to be overcome.

Of the 5 parts, the first and the last are most likely to appeal to the non-specialist reader. Part 1 consists of a general introduction and summary; part 5 includes chapters on the chemical composition of green unicellular algae in general, the nutritional value of *Chlorella*, and possible non-food uses of algae. The intervening parts are much more technical and detailed. Part 2 consists of 6 chapters on the biology of algae and the physical and chemical conditions favouring the growth of *Chlorella*. In part 3 experiments in several countries on the mass culture of *Chlorella*, indoor and outdoor, on an intermediate scale, are described, and in part 4 the construction and working of the pilot plant mentioned above and of a smaller installation in Japan, with photographs. There is a select bibliography.—W. M. Deans.

REGISTRAR-GENERAL. *Statistical review of England and Wales for the year 1953*. 1. Medical. H.M.S.O., London, 1954, pp. x + 365. Price 10s. net.

8. FOOD AND AGRICULTURE ORGANIZATION (AND OTHER ORGANIZATIONS) OF THE UNITED NATIONS

Monthly Bulletin of Agricultural Economics and Statistics.

Vol. 3, No. 11, November 1954, pp. 44. Price \$0.50.

No. 12, December 1954, pp. 48. Price \$0.50.

Key problems of agricultural development in the Near East.

Vol. 4, No. 1, January 1955, pp. 48. Price \$0.50.

No. 2, February 1955, pp. 48. Price \$0.50.

Development Paper No. 45. Factors affecting rice production. Rome, Italy, December 1954, pp. v + 45. Price \$0.50.

Information was obtained by questionnaire from over 30 countries and has been both summarised in text and presented in tabulated form. Large variations in yields were recorded in the different territories. It is concluded that the rice plant requires a warm temperate climate with long periods of sunshine, a 5-month growing period in soil neutral or acid rather than alkaline in reaction and good irrigation. The tables give the data under 10 headings.

Report of the special technical meeting on the economic aspects of the rice industry, Rangoon, 11-18 November 1954. Rome, Italy, 1954, pp. v + 30. Price \$0.25.

Delegates attended from 17 countries exporting and importing rice. They considered the situation as it was affected by the rise in rice production reported in 1953 and 1954 from territories other than China and the U.S.S.R. Governments appeared still to be encouraging production. The recommendations were that increases in consumption should be encouraged in areas where the energy requirements for sustained work cannot be supplied or where the prewar level of consumption has not yet been regained. The creation of larger stocks in both exporting and importing countries would have a steady effect on prices.

Commodity Reports. Rice No. 5. Rome, Italy, December 1954, pp. 38. Price \$0.25.

The work of FAO 1953/54. A progress report. Rome, Italy, July 1954, pp. 60 (mimeographed).

The report, with a preface by the Director-General, describes the Organization's work and the many confer-

ences and regional meetings which it has arranged. There are chapters on Agriculture, Economics, Fisheries, Forestry and Nutrition. The report of the Committee on Calorie Requirements (see p. 517, Vol. 20) is under review and the possibility of relating agricultural production to nutritional requirements is thought to be nearer attainment.

The disposal of surpluses in such a way as to benefit the vulnerable groups was studied in association with UNICEF. In the Near East and in Libya and Iraq the feeding of Arab refugees and of pupils in schools has been arranged and similar help has been given to schools in Central America and Panama. In Brazil the question of protein malnutrition, with signs in children similar to kwashiorkor in Africa, was examined. The need for protein-rich foods prompted work on the preparation of fish flour and on the collection of information from many areas on local foods which are rich in that nutrient. The processing in India of fruit that formerly went to waste, increasing the efficiency of canning practice in Yugoslavia and improvement of baking methods in Chile and Israel are examples of problems in food technology which were examined. The addition of chemicals to foods was studied in association with WHO.

Activities of FAO under the Expanded Technical Assistance Program 1953/54. Rome, Italy, December, 1954, pp. 84 (mimeographed).

This report should be read in conjunction with the Progress Report (see above). It gives, mainly on a regional basis, a description of the work undertaken by FAO for the Technical Assistance Board and the numbers and fields of study of FAO Fellowships awarded in connection with projects which are included in the Programme. In addition four selected projects are described in greater detail; improvement of processing of hides and skins in Libya, irrigation schemes in East Pakistan, development of fisheries in Chile and ground water development in Syria.

Report of the Council of FAO, Twentieth Session, 27 September-8 October 1954. Rome, Italy, November 1954, pp. vii + 100.

Linseed oil meal as supplement for wintering long-yearling bullocks.
Hay to grain ratio in rations of beef bulls.
Consumption of pine needles and abortion in pregnant cows.
Dry meal starter ration for pigs weaned at 10 days.
Mouldy cereal grains in pig feeding.
Alfalfa in ration of pregnant sows.
Measurement of pasture production affected by animal weight variations.
Response to growth stimulants in poultry feed affected by environment.
Surplus fish as poultry feed.
Goosings intolerant to excess protein in the ration.
Use of inedible fat in poultry rations.
Sunflower seed oil meal for poultry.
Effect of iodinated casein on fertility (poultry).

INDIA.

Indian Council of Medical Research. Nutrition Research Laboratories, Coonoor. Annual Report for the Year 1953-54. Pp. 27.

Stability of vitamin A to domestic cooking procedures.
Mode of action of vitamin D in relation to carbohydrate metabolism (rat).
Nutritive value of duck egg white (rat).
Metabolism of animal and vegetable protein: rate of excretion of urinary N; blood sugar and urinary N (rat).
Body composition of normal Indians and changes in undernourished subjects during rehabilitation; cell solids as reference standard for B.M.R.; electrocardiographic changes in severe undernutrition.
Kwashiorkor: treatment with Bengal gram; blood chemistry; pathogenesis of liver injury.
Metabolic interrelations of folic acid, vitamin B₁₂ and citrovorum factor in anaemia.
Vitamin B₁₂ and growth of children.
Vitamin B₁₂ and protein metabolism (children).
Growth and skeletal growth of Indian children.

FEDERATION OF MALAYA.

Institute for Medical Research. Annual Report for the Year 1953. Pp. 104.

Losses of nutrients during the washing and cooking of parboiled rice by different methods (ash, Ca, P, Fe, phytic acid P and vitamin B₁).
Estimation of vitamin B₁ in rice and rice products.
Kwashiorkor.
Protein and methionine levels in blood and human milk.
Study of poor Chinese diet.
Vitamin B₁ in human milk.
Anaemia in South Indian labourers and role of folic acid and vitamin B₁₂.

NEW ZEALAND.

New Zealand Dairy Board. 30th Annual Report for the Year ended July 31, 1954. Pp. 102.

SOUTHERN RHODESIA.

Annual Report of the Nutrition Council (Southern Rhodesia) for the Year 1954. Pp. 9.

Tempe (fermented soya bean) production.
Fortification of maize meal with calcium, riboflavin and nicotinic acid.
Addition of sorghum, bulrush millet and/or maize to wheat bread.
Investigations on kwashiorkor.
Incidence of endemic goitre.

UNITED STATES OF AMERICA.

University of Florida, Agricultural Experiment Stations. Annual Report for the Fiscal Year ending June 30, 1953. Pp. 354.

Mineral requirements of cattle (Ca, P, Cu, Co, Fe).
Biological analyses of pasture herbage.
Beef yield and quality from various grasses and clovers and grass mixtures: effect of fertilisers.
Effect of aureomycin on sows during reproduction and lactation.
Transfer of minerals through the placenta and their distribution in the foetus (rat, rabbit, guinea pig).
Citrus meal for pigs.
Supplements to low-gossypol cottonseed meal for pigs.
Effect of reducing and discontinuing aureomycin during the growing-fattening period (pig).
Effect of aureomycin on protein requirement and carcass characteristics (pig).
Sunflower seed meal for fattening pigs.
Antibiotic implants for baby pigs.
Ammoniated citrus pulp for cattle.
Interrelation of copper, molybdenum and phosphorus (rat, rabbit).
Sunflower seed meal as protein supplement for bullocks.
Waste beef fat for growing-fattening pigs.
Content of B complex vitamins in the tissues of sows receiving radio-active Ca and Mo prior to slaughter.
Protein level and aureomycin supplementation: their influence on B complex vitamins in pig tissues.

N.A. and R. April 1955

Post partum development of bovine stomach compartments and observations on characteristics of their contents.

Effect of aureomycin on performance of dairy calves.

Effect of dietary pyrimidine ribose nucleic acid and some of its probable precursors on dairy calves.

Effect of dietary practices and previous illnesses on carpal development of children.

Effect of carotene or vitamin A deficiency in young rats on subsequent life pattern.

Nutritional deficiency in young rats in relation to subsequent malformation of bones.

Effect of dietary habits on composition of blood in the aged.

Utilisation of calcium and phosphorus by poultry as determined with radio-active isotopes.

Iowa State College. A Report of the Division of Agriculture, Research, Resident Instruction, Extension, for the Year July 1, 1953 to June 30, 1954. Pp. 58.

Effect of different antibiotics on weight gain and health of calves.

Beef production on low-quality roughage.

Antibiotics of less advantage to older dairy heifers.

Antibiotics for runt pigs.

Effect of antibiotics on vitamin requirements (pig).

Effect of different protein levels with or without antibiotics on growth of pigs.

Fats in the ration of poultry.

REGULATION OF CALORIE INTAKE AND WEIGHT: EXISTENCE AND CHARACTERISTICS	598	REFERENCES	610
MORPHOLOGICAL SUPPORT AND POSSIBLE MECHANISMS	600		

INTRODUCTION

THE development of the literature on the regulation of food intake presents idiosyncrasies almost unique in the history of physiology. In the course of the past thirty years, an enormous mass of writing, on the psychology of normal and abnormal appetite has appeared. By contrast, advances on the physical side have been few and often unnoticed. It is as though, to compare the regulation of food intake with another basic regulation, that of oxygen intake, thousands of articles had been written dealing with the psychological components of "air hunger", with only occasional allusions to desultory studies on the humoral, nervous and muscular machinery which day in and day out provides our organism with the required oxygen.

It is true that the conscious compulsive effects of hunger are striking. One may recall, for example, the stories of North American pioneers crossing the continent in wagon convoys, driven by want of food to cannibalism, and of fights for food between fellow inmates of concentration camps systematically starved by their jailers for the express purpose of breaking their spirit. These and similar examples illustrate the fact that hunger is one of the most irresistible stimuli to human action. Keys and his co-workers (1950) have analysed the progressive deterioration of attitudes as starvation progresses. It would seem that the very compulsiveness of these urges should have been taken more generally as a proof of the potency of the underlying somatic mechanism.

The fact that the giving of food by the mother to her children and the partaking of food with family and friends have become such strong symbols of personal relations, is evidence of the universal, primary importance of satisfying calorie requirements.

The emphasis on the psychological side of the regulation of food intake is doubtless due largely to intense professional and popular interest in the problem of obesity, particularly in the United States. Because of the prolonged failure of physiologists to study the etiology of obesity more deeply than by establishing the presence of a positive energy balance, it has been assumed and repeatedly proclaimed that obesity is fully explained by habitual overeating, due to lack of self-control. Such a view, exemplified by the classic article of Newburgh (1944), is still widely held. Any possible search for deeper causes was frowned upon, if not discouraged, because it might allow the obese to diminish the blame with which they were stigmatised, if it was once conceded that genetic factors, or hormonal imbalance, or an inactive mode of life imposed by the environment, could be made to share the blame with gluttony. The old view of medicine, still to be found in many primitive groups and in some western sects as well, that patients are sick because of their sins, including their lack of self-restraint, has been in great part abandoned in the western world. Even in alcoholism, it has long been felt that simply to state that habitual over-drinking is due to lack of

self-restraint is not a sufficient explanation. But a stern, censorious attitude to over-eating, or a pitying superior one, is still frequently encountered and is disappearing only as the search for deeper causes progresses.

One would expect that the general failure of therapeutic methods based on appeals to the mind would have led to a questioning of the purely psychological theories of obesity. A recent Boston study by Bowser *et al.* (1953) clearly demonstrates the dismal long-term failure of psychological approach. Three years after four large groups of obese patients had been characterised as obese and, respectively, left untreated, referred to a hospital diet clinic, subjected to group psychotherapy or subjected to individual psychotherapy, the trends of weight changes in the groups were compared. No difference was apparent and, on the average, little improvement was noted. Short-term effects of the treatments had had no lasting value. Similar experiences are reported by Aldersberg and Mayer, M. E. (1949), Danowski and Winkler (1949), and Wolfson (1954). In the paediatric field the prominent psychiatrist, Hilde Bruch (personal communication), has remarked on the near impossibility of permanently reducing the weight of children who have progressed steadily along an "obese" channel of the Wetzel grid. These facts lead one to suspect that perhaps many obese patients are effectively, indeed compulsively, "regulated" for an excessive intake or weight. The generally derided statement of the obese, "... but I eat like a bird", may not imply any attempt at deceiving others or himself but may show that the patient, far from being conscious of "stuffing himself" is all the time failing to satisfy his appetite fully. To defy the "regulation" for long would be as difficult for such patients as for normal persons to starve themselves in the presence of available food. Such a view is strengthened by the difficulties encountered in trying to increase the weight of abnormally thin subjects (Rony, 1940) and even, sometimes, of obese subjects as well, for instance, the 98 kg. subjects of Nadal and co-workers (1954) who, try as they might, never succeeded in qualifying for the "Club des 100 Kilos". Rather than hasten into premature moral judgments, it seems more appropriate to seek to understand the mechanism of normal regulation of food intake before its abnormalities are explained or made a moral issue. While palliative starvation methods may work as long as equally strong instincts, such as overriding fear of death or intense desire for sexual reward, counterbalance the drive to eat, only systematic and rational research can lead to lasting cures for the resistant forms of obesity. This review is an attempt to sum up the present knowledge of the physiological aspects of the etiology of obesity.

REGULATION OF CALORIE INTAKE AND WEIGHT: EXISTENCE AND CHARACTERISTICS

Leaving aside, at least temporarily, the conscious aspects, such as the sensations of hunger and appetite complex, let us examine the nature of the physiological problem confronting us. A previous definition of the problem (Gasnier and Mayer, A., 1939; Mayer, J., *in press*) can be re-formulated into the fourfold question: (1) Is there a regulation, or are there regulations? (2) What is regulated? (3) How well is it regulated? (4) How is it regulated? In short, what are the mechanisms in terms of structure and function? That order will be followed in reviewing the available evidence.

IS THERE A REGULATION?

Gasnier and Mayer (1939) first showed that the question whether a regulation exists is most easily answered not by considering the food intake but by observing the constancy, within a given environment, of total bodyweight, water content, reserves other than water, nitrogen balance and fat content. Their evidence, obtained on a large group of rabbits carefully studied for a long period, is highly conclusive that a regulation does exist. Similarly Kennedy (1952-53) showed that the hypothalamic-hyperphagic rat in the static phase is regulated for weight in the same way, and we have demonstrated a similar persistence of regulation in other forms of experimental obesity.

WHAT IS REGULATED?

It has been shown (Gasnier and Mayer, A., 1939; Mayer, J., *in press*) that three types of regulation could be defined.

BIOMETRIC REGULATION

The term biometric regulation was first introduced by Gasnier and Mayer (1939) and applied to the regulation of energy exchange. The regulation is not, properly speaking, a mechanism, but is the result of a necessity imposed by the structure of the animal itself, of its cells, organs and systems. It simply sets limits both upwards and downwards to energy exchange, the limits for expenditure being as a maximum, the "summit metabolism" of Giaja (1925), and as a minimum, basal metabolism and its variations. For food intake, the upper limit has since been explored by Kennedy (1952-53), who showed that, in the rat, lactation, not hypothalamic hyperphagia, represents the peak of intake and that intake is not further increased by superimposing hypothalamic hyperphagia on lactation, although intake in lactation can be increased by superimposing cold.

The concept of biometric regulation can be applied also to weight and to the fat content of the organism. The lower limit is set by the minimum protein and fat content compatible with life, the "éléments constants" of Terroine and Sorg-Matter (1920; 1928). The upper limit is set fairly rigidly as far as the protein content of the body is concerned, and can be raised only slightly by high-protein diet and exercise. As far as fat is concerned there may be a limit also set by the number of adipose cells in the body (Tanner, 1954, in press). Recent work from this laboratory (Mayer and Silides, to be published) shows that progressive accumulation of fat in obesity eventually reduces the rate of lipogenesis from acetate and from glucose. The two probably related facts, limited number of adipose cells and slowing down of fat deposition as obesity develops, may combine to impose an upper limit to the amount of fat which can be carried by a given individual. In the rare disorder known as histiodiuresis (Lawrence, 1946), the organism is incapable of depositing fat. Such a condition represents a pathological reduction of the upper biometric limit of fat content.

If the margin of variation of these biometric regulations of calorie intake and body fat were small, there would be no need for any additional regulation. In fact, however, the margins are large, thus allowing the animal to adapt itself to variable environmental conditions. Regulations, properly speaking, operating within the biometric limits are thus necessary to maintain a steady state.

ADAPTATION OF ENERGY INTAKE TO ENERGY OUTPUT (SHORT-TERM, GENERALLY DAY-TO-DAY, REGULATION OF ENERGY INTAKE)

Adaptation of intake to output appears to be the most important mechanism; it adjusts intake to requirements. Gasnier and Mayer, (1939) exemplified it by showing that when a large number of animals were followed for a long time under varying conditions of energy expenditure there was a high degree of correlation between daily intake and output. They used rabbits made to live at 30°, 18° or 0°, or shaved and made to live at 18° or 8° C.

CORRECTIONS OF THE ERRORS IN THE SHORT-TERM MECHANISM OF REGULATION OF FOOD INTAKE BY SUCCESSIVE COMPENSATIONS: LONG-TERM REGULATION OF RESERVES, CLOSELY RELATED TO REGULATION OF BODYWEIGHT

If in the experiment of Gasnier and Mayer just recalled the energy balance was strictly in equi-

librium each day, all points would be on the straight line at a slope of 45° going through zero. Actually, it was found that the points were not strictly on the line, but in a band spread on both sides of it. It follows from the existence of such a range that the day-to-day regulation is not sufficient to ensure constancy of bodyweight and of body reserves.

If there is oscillation of weight and reserves round a constant value, the "error" of the day-to-day regulation is in itself evidence of a supervening regulation. When for a series of 24-hour periods the percentage change of dry bodyweight in each period is plotted against the value at the beginning of that period, a distribution is obtained which lends itself to the following conclusion: on a given day, the farther away from the modal change the amount of reserve acquired, the greater are the chances that, during the next twenty-four hours, (a) if the change is in the same direction it will be small, or (b) if the change is in the opposite direction it will be large enough to approach or pass the mode. There is thus a long-term mechanism which in effect, under constant environmental and physiological conditions, tends to maintain the constancy of bodyweight.

HOW WELL DO THESE REGULATIONS FUNCTION?

Given a regulatory mechanism, it is useful to characterise its efficiency. The scope of this review does not allow for a detailed discussion of this topic. In summary four parameters have been defined which permit the quantitative description of how well both the day-to-day adjustment of intake to output, and the long-term regulation of bodyweight, function. These parameters are: precision, reliability, sensitivity and rapidity. Rigorous definitions have been given elsewhere (Gasnier and Mayer, A., 1939; Mayer, J., in press). For the short-term regulations, functional definitions of these parameters would be as follows:

1. Precision; inversely proportional to the difference between energy intake and energy output.
2. Reliability; whatever the precision, if day by day the ratio was the same, the mechanism would be reliable.
3. Sensitivity; if the precision is dependent on the size of energy intake and energy output, then the sensitivity is variable.
4. Rapidity; this is measured by capacity to adjust energy intake to output in, say, 24 hours.

Corresponding definitions have been evolved for the long-term regulation. It has been shown that it is possible to ascribe precise numerical figures

to these parameters. Furthermore, when the effect of different conditions, such as temperature, exercise, calorie dilution, state of hydration, change in the nature of the diet, is considered, it becomes possible to determine with precision not only the mean intake and bodyweight corresponding to a new equilibrium, but also the extent to which the regulatory mechanisms as characterised by their precision, reliability, sensitivity and rapidity have been disturbed. For example, such a detailed study has been conducted on the effect of environmental temperature on the long-term and short-term regulation (Gasnier and Mayer, A., 1939; Mayer, J., in press). In adapted animals, as the temperature falls, both energy output and energy intake increase; the reliability of the short-term regulation adjusting intake to output increases, its precision remaining the same. As regards the long-term regulation, body reserves increase, the precision and reliability of regulation increase, but the sensitivity and rapidity decrease with increasing metabolic intensity. Analogous, though less thorough, studies have been made of the effect of environmental temperature on regulatory mechanisms in hypothalamic obesity (Kennedy, 1952-53) and of enforced exercise on regulatory mechanisms in normal and obese animals (Mayer *et al.*, 1954) and in man (Mayer, 1955b, in press).

HOW DO THE REGULATIONS WORK?

The answer to the question, What are the mechanisms of these regulations? is still tentative. Let us review briefly first what is known of the morphological support of the regulation, then some of the possible modes of integration of the mechanisms. It should be unnecessary to note again that, when speaking of mechanisms of regulations, time is all-important. As underlined by Kennedy (personal communication) short-term tests demonstrate the influence of a multiplicity of conditions on appetite and emphasise instability. The long-term reactions, be they for one day or longer periods, emphasise stability. It is, in a sense, the mechanism of this stability which is under consideration.

It should be equally unnecessary to point out at the outset that all investigators whose theories are about to be reviewed have recognised the weakness of any general theory of appetite founded on response to only one stimulus, and they have not attempted to erect such systems. Their problem has been to find a means of expressing the underlying continuity as a force which, at a given time, would compete with other influences successfully enough to impose long-term stability. The mechanisms about to be reviewed are thus concerned with the control of food intake and its role in determining feeding pattern.

REGULATION OF CALORIE INTAKE AND WEIGHT: MORPHOLOGICAL SUPPORT AND POSSIBLE MECHANISMS

MORPHOLOGICAL SUPPORT

GASTRO-INTESTINAL TRACT

The earliest correlation reported between the state of hunger and objective physiological phenomena was the finding by Cannon and Washburn (1911-12) that sensations of hunger appeared simultaneously with contractions of the stomach. The hunger contractions were further investigated by Carlson (1914), who found that in starvation the tonus and the frequency and intensity of the contractions of the empty stomach became progressively more pronounced in the course of the fast, at least until the fourth day. Until that time, too, the appetite for food increased. On the fourth day both hunger contractions and desire for food decreased. These stomach hunger contractions are relatively powerful, occurring in series of from twenty to seventy, and lasting usually between half an hour and one hour and a half; they alternate with periods of quiescence. The contractions are seen in new-born babies before the infant has had any experience of food. Their presence is general in land vertebrates, whether homoiotherms or poikilotheims.

Hunger contractions are present even when some food is present in the stomach. The only time when the fundus does not exhibit them is immediately after a large meal. They occur after isolation from the brain and spinal cord, though at longer intervals and with less vigour. They are inhibited by a variety of stimuli, the tasting or chewing of a palatable food, or even of an inert substance like paraffin wax, unless the contractions have become tetanic in nature; swallowing movements, even without food in the mouth; stimulation of the gastric mucosa by ice-cold water, acid, alcohol, smoking, tightening of the belt, vigorous muscular exercise, sudden applications of cold, emotions such as fear or rage, adrenaline, glucose infusion under conditions of normal utilisation (Stunkard and Wolff, in press). Inhibition of gastric contractions can be brought about also by irrigation of the duodenum with glucose. A counteracting humoral factor, a chalone, has been postulated on the basis of studies on dogs with a completely denervated stomach or a completely denervated autotransplanted gastric pouch (Quigley and Phelps, 1934). Carlson considered that the vagi were the main, if not the only, afferent pathway for the gastric hunger impulses and that the "primary hunger center" must therefore be the "sensory nuclei of the vagi" in the medulla (fasciculus solitarius). Interesting modifications

of gastric tone take place in disease; duodenal ulcer and diabetes cause an increase, pulmonary tuberculosis and vitamin B₁ deficiency a decrease.

The possible relation of intestinal phenomena to hunger has attracted some attention. The forward movement of food in the small intestine has been studied by Cannon (1901), Carey (1921), Quigley and Lindquist (1930), and Reid *et al.* (1934). The character of the peristaltic movement has been shown to be connected with the chemical composition of the chyme, with acid, alkali and some of the products of digestion which may have an effect on the contraction of the muscle. As is well known, the small intestine, like the stomach, obtains its supply of extrinsic nerve fibres from two sources, a bulbar autonomic (parasympathetic) supply by way of the vagi and a thoracic autonomic (sympathetic) supply by way of the splanchnic nerves and the superior mesenteric ganglia. Stimulation of the vagi causes contraction or increased tonus in the musculature of the intestine; stimulation of the splanchnic nerves generally inhibits its tonus. Psychological states and stimulation of portions of the cerebral cortex may produce contraction or relaxation of the walls of the small and large intestines. Adrenaline, like splanchnic stimulation, inhibits intestinal movements; oxygen, organic acids and bile increase them. The sensory fibres from the intestine are carried by the vagus and the splanchnic nerves.

CENTRAL NERVOUS SYSTEM

Pathological studies of patients with hypothalamic obesity first established the importance of this part of the central nervous system in the control of food intake. Experimental work by investigators on both sides of the Atlantic clearly eliminated pituitary lesions from the possible causes. The early development of our knowledge of this syndrome has been reviewed previously by Brobeck (1946) and Mayer (1953c). Identification of the regions in which discrete lesions will cause obesity has been advanced by surgical exploration as well as by the use of stereotaxic instruments. The rat has been studied particularly by Hetherington and Ranson (1940; 1942) and by Brobeck and co-workers (1943). They found that bilateral involvement of the ventromedial nuclei caused hyperphagia. Mayer and Barnett (1955) have since found that in the rat unilateral destruction of the ventromedial nucleus caused slow development of obesity. Hypothalamic obesity in the mouse has been produced by Mayer, French *et al.* (in press), who found that in that species bilateral involvement of the ventromedial nuclei was necessary. In the monkey, Brooks *et al.* (1942) found that obesity follows superficial lesions of the base of the anterior hypothalamus. In the dog,

Heinbecker *et al.* (1944) produced obesity by lesions caudal to the paraventricular nuclei. Development of the condition appeared to depend on the interruption of descending fibres leaving the ventromedial nuclei. Conversely, Anand and Brobeck (1951a) found in rats that bilateral destruction of more lateral parts of the hypothalamus was followed by complete cessation of eating. Teitelbaum and Stellar (1954) confirmed this finding, although they found that inhibition was usually temporary. The areas destroyed included the extreme parts of the lateral hypothalamic nucleus at the same rostro-caudal level as the ventromedial nucleus.

Stimulation of hypothalamic structures has proved equally informative. Brugger (1943), who compiled the results of electrical stimulation in the hypothalamus reported by Hess (1949), found that stimulation in the vicinity of the mamillothalamic tract produced morbid appetite not only for edible but also for indigestible material. Delgado and Anand (1953), working on monkeys, found that temporary increases in food intake followed electrical stimulation of the lateral hypothalamus at the level of the ventromedial nucleus.

Larsson (1954) made a particularly careful study of the results of electrical stimulation of the hypothalamus and the medulla and of intrahypothalamic injections in sheep and goats. He found that stimulation of the hypothalamus, just caudal to the optic chiasma backwards throughout the hypothalamus, lateral to the sagittal level through the columna fornx descendens and the mamillothalamic tract, resulted in hyperphagia. The most pronounced effect was obtained by stimulation of the region of the lateral hypothalamic nucleus, anterior to the columna fornx descendens or at the same transverse level as this tract. Rumination was seen on electrical stimulation of the same structures as gave hyperphagia. Of particular interest was the fact that, as was previously observed by Magoun (1940) and by Hess (1948; 1949), mastication, licking and swallowing could be elicited as single effects without the simultaneous occurrence of hyperphagia. Larsson (1954) felt that the concept implicitly or explicitly presented by Brugger (1943) and by Anand and Brobeck (1951b) of the existence of a feeding centre in the mamillothalamic area, or in the antero-lateral hypothalamus, was not strictly supported by his findings; although electrical stimulation of both these areas, particularly the latter, caused hyperphagia, the fact that extra masticatory and licking movements as well as hyperphagia were obtained diffusely in other areas support the conclusion that while the feeding pattern is closely related to regulation of food intake, the two mechanisms rest on centres which are in part differentiated. Similarly, it had been

shown previously by Ström and Uvnäs (1950) that inhibition or activation of movements of the stomach and intestine could be caused by electrical stimulation of different hypothalamic areas.

Besides the hypothalamus, the thalamus appears to be involved in the regulation of food intake. Ruch and co-workers (1941) showed that in the monkey damage to the ventromedial portion of the thalamus and rostral mesencephalic tegmentum caused obesity. The optic nuclei have been implicated by Rogers and Hardt (1915), who showed that normal feeding habits were upset by destruction of the optic nuclei. Separation of the frontal lobes from their thalamic connections also has been shown by Richter and Hawkes (1939) to lead to obesity in rats. Similar findings obtained on lobotomised patients have been reviewed previously (Mayer, 1953c). Finally, the importance of cortical phenomena in the regulation of food intake hardly needs to be emphasised. Kirschbaum (1951) has shown that selective decortication may lead to hyperphagia.

MECHANISMS

GASTRIC CONTRACTIONS AS A BASIS OF HUNGER AND REGULATION OF FOOD INTAKE (CARLSON)

The views of Carlson (1914) on the relation between gastric pangs, hunger and the regulation of food intake have been summarised in his book, and are well known. They constitute the oldest attempt to account *experimentally* for these phenomena. For Carlson, the consciousness of gastric sensations, carried by the vagi, is the kernel of the problem. Hunger is defined by him as "a more or less uncomfortable feeling of tension or pressure and pain referred to the region of the stomach". Like Cannon and Washburn (1911-12), he considers that an explanation of the hunger pangs is an explanation of "the control of hunger in health and disease". He does recognise, however, that "many apparently normal persons experience in hunger, besides the gnawing pressure-pain sensation in the stomach, a feeling of weakness, 'emptiness', headache and sometimes nausea", but calls those states or symptoms "accessory hunger phenomena" because "they are not always present in hunger and their relative preponderance depends on the length of starvation and on some individual peculiarity in the person. It must be admitted, however, that in some individuals, these accessory hunger phenomena appear to overshadow, if not entirely to suppress, the pressure-pain sensations from the stomach." In turn, Carlson, struck by the fact that insulin hypoglycaemia leads to gastric contractions and hunger feelings, postulated that blood glucose levels were involved in the occurrence of hunger.

This theory received wide, although temporary, acceptance. Besides Carlson, it was expounded by Cannon (1901), Quigley and co-workers (1929), and Templeton and Quigley (1930). Although the existence of hunger pangs has been abundantly confirmed, accumulating facts led observers to doubt whether gastric movement provided a sufficient basis for Carlson's generalisation. For example, Adolph (1947) showed, by diluting the ration of experimental animals with inert material, that differences in the bulk of the diet had only a very transient influence, and Morgan and Morgan (1940), working with rats, and Grossman and co-workers (1947) with dogs, demonstrated that complete bilateral vagotomy, which abolishes the gastric motor response to insulin hypoglycaemia, does not prevent or even impair the augmentation of food intake produced by insulin administration. The existence of patients in whom bilateral vagotomy had been performed for the treatment of peptic ulcer enabled Grossman and Stein (1948-49) to extend these findings to human subjects; they found that the sensations of hunger induced by insulin continued to occur after complete vagotomy. The sensations included feelings of emptiness and weakness. In those persons in whom epigastric pangs of distress associated with individual gastric contractions were a part of the sensation-complex of hunger, vagotomy, by abolishing the contractions, eliminated that particular part of the sensation. Though the removal of that component of the sensation-complex was recognised by the subject, it did not cause a significant change in the general effective response to hunger.

Disagreeing with Carlson (1914) and Quigley *et al.* (1929), Grossman and Stein (1948-49) state that in most of their subjects the gastric component of the hunger sensations was absent or negligible both before and after vagotomy, and vagotomy caused no detectable change in the hunger response to insulin. Thus, while both gastric and extra-gastric stimuli contributed to hunger sensations in man, it appeared that in most persons the extra-gastric components predominated in the sensation complex of hunger. Elimination by vagotomy of the gastric component of the hunger-sensation complex had no significant effect on the manifestations of the extra-gastric components, the feelings of weakness and emptiness associated with the desire for food.

Actually, Grossman and Stein differed from Carlson not only about the significance of gastric contractions but on their mode of perception as well. While Carlson, following Miller (1911), had claimed that "the vagi nerves are the main, if not the only, afferent pathway for the gastric hunger impulses", Grossman and Stein found that in two patients who had undergone sympathectomy persisting gastric contractions were no longer

associated with a feeling of distress. On the basis of this finding they concluded that the splanchnic nerves are the afferent pathways for the distress associated with gastric hunger contractions and that no such pathway exists in the vagus nerves.

With the decrease of the significance of hunger pangs, interest in their causation died down. Scott alone and with his co-workers (1938) could find no correlation between absolute blood sugar levels and the onset and prevalence of hunger contractions.

It appears legitimate to conclude that while hunger pangs exist and in many individuals are the basis for the gastric component of hunger, a mechanism of regulation of food intake can hardly be based exclusively on their perception. On the other hand, any theory purporting to represent regulation of food intake which cannot account for the occurrence of hunger pangs is doomed at the outset.

THERMOSTATIC THEORY (BROBECK)¹

Brobeck (1948) was struck by the fact that the hypothalamus appeared able to deal with a number of different stimuli which affect feeding behaviour and to make a suitable adjustment of food intake. The common characteristic of these factors seemed to him to be that they affected the heat balance of the body. He accordingly advanced a "thermostatic" hypothesis which postulated that "animals eat to keep warm and stop eating to prevent hyperthermia". The actual experimental evidence for his view rested first of all on the observation that short-term exposure to high environmental temperature is followed by reduction of food intake. Kennedy (1952-53), however, claimed that under the extreme conditions in which Brobeck's animals were placed, dehydration and

pyrexial tissue breakdown played a major part in the weight loss following acute exposure to heat. Acute exposure to cold also caused depression of food intake at first. Working with hypothalamic-hyperphagic rats he demonstrated that in the long run, and as long as his animals stayed within the range of adaptation, they showed similar rates of weight gain at high temperatures and at low temperatures. Perhaps an even more serious objection to a thermostatic scheme was the finding by Mayer and Greenberg (1953) that the internal temperature of rats is raised when they are fasted.

Another piece of evidence used by Brobeck (in press) in support of a thermostatic scheme is the fact that a change from a high-carbohydrate to a high-fat diet usually increases food intake, and a change from a high-carbohydrate to a high-protein diet decreases it. The specific dynamic action of proteins is greater than that of carbohydrates, which in turn is greater than that of fat. He felt that this observation enabled him to postulate that modifications of intake follow perceptions of differences in specific dynamic action. However, it has been repeatedly shown that the differences in intake following changes from high-carbohydrate to high-fat diet are transient. Their impermanence has been demonstrated in particular by Cowgill (1928) and by Lundbaek and Stevenson (1947). Fenton and Dowling (1953) and Lyon *et al.* (1953) have found that in mice the situation could be complicated by genetic idiosyncrasies. In some strains, both intake and output go up on a high-fat diet, in others intake alone goes up. In experimental obesity, results of changes of diet vary with the type of obesity considered. For instance, Marshall and Mayer (1954) found in goldthiogluco obese mice and Mayer, French *et al.* (in press) in hypothalamic obese mice that spontaneous food consumption, measured as calories, was highest on a high-fat diet, high on a high-carbohydrate diet, and almost normal on a high-protein diet. In the hereditary obese-hyperglycaemic syndrome of mice, spontaneous consumption was lowest on a high-fat diet and highest on a high-carbohydrate diet (Mayer and Jones, 1953).

Finally, it would appear that the validity of a thermostatic theory would be limited to homeotherms. It may be pointed out also that, though the theory raises the important problem of integration between various physiological regulations, it gives little consideration to the equally necessary integration between the regulation of food intake and that of intermediary metabolism. It fails to account for the frequency of meals or for gastric hunger pangs. It does not account for the effects on appetite of disturbances of carbohydrate metabolism; for example, diabetes and hyperinsulinism affect appetite without being accompanied by disturbances of body temperature. A

¹ The reviewer hopes he is not misrepresenting Brobeck's attitude when synthesising some of his recent papers into a "thermostatic theory". He would like to add that if he is guilty of such a misrepresentation, the responsibility is his own, all the more so that he admits that the position of Brobeck is often obscure to him. Short-term reactions, which Brobeck (in press) has studied, permit a listing of factors influencing food intake. These can be obviously integrated in a Sherringtonian concept and made to interpret feeding behaviour at a given time. Such a "synthesis", however, gives no clue to the possible mechanism of homeostasis. In some of his writings (*e.g.*, 1948) Brobeck has postulated such a regulating, or at least limiting, mechanism, based on his thermostatic concept. This point of view is summarised here. In other writings (*e.g.*, in press), he has either denied the existence of a homeostatic mechanism adapting intake to output, because, at a given time, factors other than the energy content of food determine its intake, or postulated an "energy memory" which has yet to be given material substance.

thermostatic mechanism would logically lead one to predict anorexia in hyperthyroidism and hyperphagia in hypothyroidism.

SOULEIRAC'S THEORY OF CARBOHYDRATE APPETITE REGULATED BY INTESTINAL ABSORPTION

Souleirac limited himself to the study of appetite for carbohydrate in rodents. However, his numerous publications (1944; 1945; 1946a, b; 1947a, b, c), later collected in book form (1947d), deserve a somewhat detailed analysis. His work has the original merit of being directed towards the quantitative account of a qualitative appetite, and thus provides facts which may eventually be used to integrate taste and calorie intake. Souleirac was struck by the observation that phloridzin, which, according to Carlson, increases gastric contractions, inhibited appetite for carbohydrate. Thyroidectomised and adrenalectomised animals, both of which present hypoglycaemic tendencies, also show diminished appetite for carbohydrate. The observation led to a search for possible correlations between carbohydrate appetite and physiological characteristics. Using a self-selection method, Souleirac systematically examined the quantitative and qualitative variations of uptake of different types of sugar after removal of the anterior pituitary, thyroid, and adrenal glands, alloxanisation of the pancreas and administration of the corresponding hormones, anterior and posterior pituitary extracts, thyroxine, "cortine" and deoxycorticosterone and insulin. He concurrently studied the modifications of taste threshold for carbohydrates and, using the technique of Cori (1926), the effect of the endocrine disturbances just listed on the intestinal absorption of carbohydrates. Similar studies were made after administration of adrenaline, ergotamine, pilocarpine, acetylcholine and atropine, after spinal section in the cerebral region and hypothalamic lesions, or after administration of glucose, riboflavin and phosphate. The effects of cold and physical exercise also were examined. Estimations of blood glucose and of serum amylase were made after these procedures. Souleirac found that there was no correlation between either absolute blood sugar level or the level of serum amylase and carbohydrate consumption. On the other hand, he found that all hormones with an effect on carbohydrate metabolism modified the taste threshold for glucose, though the interpretation of the modifications was difficult. By contrast, the correlation between the taste for carbohydrates and the intestinal absorption of carbohydrates was clear-cut. Any condition which increased intestinal absorption increased consumption and, conversely, if carbohydrate absorption was decreased, carbohydrate intake was decreased. For instance,

injections of glucose depressed absorption of glucose and glucose intake; phloridzin and thyroidectomy decreased glucose absorption and intake; insulin and alloxan diabetes increased glucose absorption and intake. The only exception was provided by atropine, which slightly decreased the proportional absorption of glucose from the intestine but considerably increased the total. Souleirac explains the effect of atropine by the intense thirst it produces.

Although the facts invoked by Souleirac are clear enough as far as they go, it seems regrettable that no data are ever given on the calorie intake of the experimental animals, but only on the amount of carbohydrate solution ingested. The omission is all the more regrettable because the solid food available, cereals and greens, constituted a high-carbohydrate diet. One would like to know also what the fluid (water) consumption in the different experimental situations was. Examination of the available information raises the question, which is not discussed by Souleirac, of how the organism detects the fact that carbohydrate is being absorbed. Souleirac observed that spinal section at the level of the sixth to seventh cervical vertebrae did not eliminate the response of the carbohydrate intake to endocrine stimulation, but then it would not interrupt splanchnic sensory connections. The increased intake after atropine treatment could conceivably lend itself to an interpretation based on the effect of the drug on the vagus. The fact that vagotomy and sympathectomy, which would seem to eliminate afferent impulses from the intestine to the central nervous system, while eliminating hunger pangs, do not eliminate feelings of emptiness, weakness and desire for food (Grossman and Stein, 1948-49), makes it unlikely that the regulation of food intake is based exclusively, or even primarily, on awareness of intestinal absorption. A humoral or hormonal intermediary could, of course, operate independently of intermediary nervous pathways, but there is no indication of the existence of such a link with the higher centres.

Souleirac suggests that the effect of the hypothalamus on the regulation of food intake is mediated through intestinal absorption; excitation of the hypothalamus would bring about a diminution of carbohydrate absorption and consumption; the action of the hypothalamus would be antagonistic to that of the pituitary and the balance between these organs would determine carbohydrate intake. While, in Souleirac's experiments, consumption of sugar solution increased after hypothalamic lesions, it is difficult to appreciate the significance of his finding that it cannot be compared with the increases also in food and water consumption which follow the operation. The incidental finding that unilateral lesions lead to increased carbo-

hydrate consumption is of interest in the light of the fact that slow development of obesity follows the production of unilateral hypothalamic lesions in the rat.

Thus, the facts presented by Souleirac, although offering an undeniable challenge, do not appear to support the mechanism he wants to base on them. His observation that any modification of carbohydrate metabolism can affect appetite and even taste, is in agreement with the postulation of the glucostatic theory (see below). It appears doubtful, however, whether, strong though the appetite for carbohydrate (or protein or salt) may be, hunger and the regulation of food intake are simply summations of selective hungers and partial regulations. Such selective appetites do exist and can be extremely compelling; the "salt wars" are bloody illustrations of their strength. Yet, compelling though such appetites are, they do not appear to overrule the general regulation. Men and animals will, it is true, eat after satiety has apparently been obtained if the supplement offered is particularly appetising, or contains a nutrient of which they have been deprived. Yet, no mammal will increase its food consumption from, say, a low-protein diet simply to satisfy a need for protein or a specific amino-acid.

GENERAL DISPOSAL (CHEMOSTATIC¹) THEORY

Glucostatic Theory for the Short-term Regulation of Food Intake. The glucostatic theory, proposed by Mayer and co-workers (Mayer, 1953b; 1953c; see also Van Itallie *et al.*, 1954) postulates that the short-term mechanism for regulating food intake operates through glucoreceptors sensitive to blood glucose. The glucoreceptors may be situated in the hypothalamic centres shown to be implicated in the regulation of food intake. The work of Souleirac opens the possibility of the existence of peripheral (gastro-intestinal) glucoreceptors as well. The idea receives some support from the earlier demonstration of the rapidity with which ingested glucose stops hunger contractions (Quigley and Hallaran, 1932) and the fact that duodenal irrigation with glucose also stops hunger contractions. The existence of glucoreceptors in the central nervous system is, of course, implicit in the fact that vagotomy abolishes the normal response to hypoglycaemia (Grossman and Stein, 1948-49; Porter *et al.*, 1953). The work of Zunz and La Barre (1927) showed as early as 1927 that when the circulation of a dog's head was isolated from that of the rest of the body, with the nerve supply

from head to body intact, hyperglycaemia of the head resulted in hypoglycaemia of the body, a finding recently confirmed and interpreted by Duner (1953). The demonstration of special receptivity to glucose and phosphorus of the hypothalamic "feeding" area given by Forssberg and Larsson (1954), related by them to atypical shifts of adenosine triphosphate and creatine phosphate during fasting, may also be taken as a partial proof of the role of these areas as glucoreceptors.

A glucostatic scheme enables one to account experimentally for the hunger state and hunger behaviour. The hunger state has been defined as the physiological state which results from prolonged deprivation of food. As far as the tissues are concerned, it consists in the low respiratory quotient characteristic of carbohydrate deprivation. Such a state is not necessarily associated with low absolute levels of blood glucose, as was believed by older workers. It has been shown by Van Itallie *et al.* (1953) that arteriovenous glucose differences (Δ -glucose), if estimated with the proper physiological safeguards and analytical care, give an easily obtainable and generally reliable measure of glucose utilisation. More detailed data on the limitations of the use of Δ -glucose values as a measure of utilisation of carbohydrates have since been experimentally obtained, and the conclusions have been discussed, by Van Itallie (1953 and in press). Consideration of Δ -glucose emphasises the characteristic common to starvation, insulin hypoglycaemia, diabetes mellitus and hunger diabetes, *i.e.*, reduced availability of carbohydrates.

It may be unnecessary to emphasise that the presence of the hunger state is not the only physiological factor influencing feeding behaviour. A number of factors may lead to those states which Janowitz and Grossman (1949) have called "hunger states without the desire to eat or without the intake of food (anorexia or hyporexia)". Conversely, hyperorexia can occur. However, in order to be valid, the glucostatic definition of the hunger state demands that it be generally accompanied by the desire to eat and that in a state of satiety the desire should be absent. Experiments performed by Van Itallie *et al.* (1953) and previously reported in detail have shown this to be true in normal animals and men, either adequately fed or underfed, and in diabetic subjects. Van Itallie (personal communication) has extended these findings to persons treated with cortisone. It has also been shown by Mayer (*Ann. N.Y. Acad. Sci.*, in press) that absolute variations in the level of inorganic phosphate follow the same pattern as Δ -glucose values, a finding which is of particular interest in the light of the later results of Forssberg and Larsson (1954).

¹ The term "chemostatic" was suggested to the author by G. C. Kennedy (personal communication), whose important contributions, suggesting in particular the role of depot fats in homeostasis (1954, in press), have already been mentioned.

Stunkard and Wolff (1954 and in press) have since shown that there was good correlation in man of small Δ -glucose values with hunger gastric contractions as recorded by the balloon technique, as well as with feelings of subjective hunger. Conversely, large Δ -glucose values were associated with the absence of gastric contractions and hunger sensations. Slow intravenous infusion of glucose in hungry individuals eliminated the feeling of hunger and the gastric contractions, except in diabetic subjects, where the impairment of glucose utilisation was demonstrated by a rise in blood sugar without a simultaneous rise in Δ -glucose values. Finally, in a neat demonstration of the fact that psychological factors operate within a physiological framework, Stunkard and Wolff showed that hunger sensations and hunger gastric contractions could be induced by psychological stimuli such as talk, sight or smell of food, provided a small Δ -glucose value testified to the existence of a hunger state as defined in the glucostatic sense.

The glucostatic theory permits the regulation of food intake to be integrated with the regulation of metabolism. It is well known that carbohydrate metabolism plays a central part in the regulation of energy metabolism. The stores of carbohydrate are small; glucose is used preferentially by all tissues and exclusively by the central nervous system. While there is a hierarchy of nervous, hormonal and humoral mechanisms designed to maintain blood sugar and, in particular, to prevent hypoglycaemia, only the taking of food will in the last resort restore normal utilisation of glucose. Carbohydrate metabolism has been implicated in the regulation of protein and of fat metabolism. For instance, Engel (1949) has shown that the availability of carbohydrates determines the rate of gluconeogenesis. Geyer *et al.* (1953) have shown that availability of carbohydrates decreases fat utilisation, and that lack of carbohydrates causes an increase in fat oxidation.

The preferential oxidation of carbohydrates during exercise and in the cold, and the decreased glucose utilisation and gluconeogenesis met with in growth, can be made to fit in with the glucostatic theory. Modifications in food intake after changing from a high-fat to a high-carbohydrate diet, or vice versa, could represent the lag in enzymic or hormonal re-adjustment to the burning of a different metabolic mixture.

The effect of metabolic hormones and disorders of metabolism also could be readily explained. Insulin treatment first causes a fall in blood sugar due to increased peripheral utilisation of glucose. In a second phase, a compensatory rise takes place which is secondary to decreased utilisation in the periphery (Somogyi, 1951). Incidentally, amphetamine curbs the increase of

appetite induced by insulin, illustrating perhaps the difference between "metabolic" and "regulatory" agents; this difference will be discussed below.

The apparent paradoxes afforded by the hyperphagia of diabetes mellitus, and by the phenomenon of hunger diabetes and other types of hyperglycaemia associated with reduced utilisation, are resolved by consideration of Δ -glucose. The effect of hyperthyroidism has been likened to hunger diabetes because of the accelerated depletion of carbohydrate stores. The complex action of adrenaline which, while it causes decreased peripheral utilisation of glucose, increases central utilisation as well as stopping gastric contractions and modifying nervous system function, has been discussed at length elsewhere (Mayer, *Ann. N.Y. Acad. Sci.*, in press). It is worth noting also that, while it is tempting to ascribe the effect of cortisone-like substances on intake and weight to decreased glucose utilisation (Van Itallie, personal communication), the few facts now available do not preclude a mechanism based on direct interference with the function of glucoreceptors. Heinbecker and Pfeifferberger (1950) have shown that in dogs prolonged treatment with cortisone or corticotropin leads to degeneration of the paraventricular nuclei of the hypothalamus and obesity. Research now in progress on obese mice with pituitary tumours secreting adrenocorticotrophic hormone may shed some light on these mechanisms.

The glucostatic theory, while it interprets certain aspects of the short-term mechanism for regulating food intake, gives by itself no clue to long-term regulation of bodyweight. The stability of weight maintained by normal animals under uniform environmental conditions (Gasnier and Mayer, 1939), by hypothalamic rats (Kennedy, 1950; 1952-53), by mice with different types of obesity (Mayer, 1955a) and by normal persons under fairly uniform living conditions, the periodic return of obese adults to the same weight (Bowser *et al.*, 1953), and the return of obese children to the same height-weight growth channel (Bruch, personal communication; Stuart, in press) are not properly interpreted by any of the short-term regulations proposed. Consideration of these problems led to the suggestion of a lipostatic hypothesis.

Lipostatic Hypothesis for the Long-term Regulation of Food Intake. Recent experimental findings obtained in the Harvard laboratory suggest that different types of normal and obese animals spontaneously mobilise each day a quantity of fat proportional to, or at least increasing with, their total fat content. The proportionality coefficient appears to depend on the type of animal, the kind of obesity in obese animals, possibly the amount

of exercise forced on the animals, the nature of the diet and the environmental temperature. Other evidence (Mayer and Silides, to be published) also suggests that as animals become more obese, the maximum rate to which lipogenesis can be pushed, by injection of insulin and glucose, decreases. The increasing saturation of the fat depots explains the tendency to reduced glucose tolerance in diabetics (a tendency which can be reversed to some extent by weight reduction (Conn, 1944)) and, since the fat appears to be readily available, may explain the transition in several types of obesity, in particular in the "regulatory" type (*vide infra*), from the "active" phase of obesity characterised by marked hyperphagia to a static phase characterised by a nearly normal appetite. The increasing saturation of the depots with fat is accompanied also by a decreased response to the stimulus of food (Anliker and Mayer, to be published) as measured by the bar-pressing method of Skinner (1951; 1953). The "lipostatic" mechanism would account for the long-term characteristic of weight regulation and, because glucose would be spared by the increasingly available fat and the resistance to greater peripheral conversion of glucose to fat, the mechanism may be readily made to fit in with the glucostatic scheme. Its experimental basis is, however, still fragmentary.

A Note on the Effect of High-protein Diets. The effect of high-protein diets on food intake deserves special mention. They decrease food intake in normal animals, and in different forms of experimental obesity (Mayer, 1953c; Marshall and Mayer, 1954; Mayer, French *et al.*, in press). They have high satiety value in many obese human subjects (Fryer *et al.*, 1955). It is noticeable, however, that while diets very high in protein (60 per cent.) tend to reduce the food intake of both normal animals and goldthioglucose or hypothalamic obese animals, variation of the protein level within the moderate range has little or no effect on food intake in experimental animals. In man, Bryant and co-workers (1952) have claimed that hunger in human subjects reappeared earlier after a low-protein meal, but Dole and co-workers (1954) obtained spontaneous reduction of intake on low-protein diets. The drastic decrease of appetite caused by giving an unbalanced amino-acid mixture would argue for the idea that the accumulated products of protein catabolism may have a limiting, in this case, toxic, effect on appetite. The mechanism of satiety at low levels of intake, if it exists, is not clear. Bryant and co-workers (1952) claim to have established steadier glucose utilisation after high-protein meals, but Fryer *et al.*, (1955) found that their obese patients felt generally more satisfied on a high-protein diet without showing steadier peripheral utilisation of

glucose. The "invisible" fat which usually accompanies protein in human meals, by delaying gastric emptying and postponing the re-appearance of the gastric component of the hunger sensation complex, makes the interpretation of subjective statements more difficult.

AN ATTEMPT AT INTEGRATION

Food intake thus operates within limits set by the biometric characteristics of the species and the individual. At a given moment feeding behaviour is conditioned by a number of environmental, physiological and psychological forces which can be classed as metabolic and regulatory. The metabolic factors depend on the general metabolism of the individual and appear to depend on the rate at which the body can dispose of certain products and consequences of eating, heat according to one theory, glucose according to another, perhaps also waste products of protein metabolism. Long-term factors also are concerned, in particular, the state of the fat depots, perhaps through a lipostatic effect (Kennedy, 1952-53; Mayer, *Ann. N.Y. Acad. Sci.*, in press) mediated through the short-term metabolic factors. The regulatory factors are conditions which act directly on the central regulatory mechanism, psychological factors or certain neurotropic drugs. This type of analysis leads one to expect that disturbances in the regulation of food intake may be in turn of two types, metabolic and regulatory. Such a distinction would apply to anorexia and emaciation as well as to hyperphagia and obesity. Both classes of phenomena will be reviewed, though examples will be chosen mostly from the field of obesity.

ABNORMALITIES OF BODYWEIGHT

An attempt has been made to list in Table 1 the different types of obesity and in Table 2 the opposite types of abnormality. It may be useful to remark at this point that the terms overweight and obesity are not equivalent. Overweight can result from causes other than generalised obesity. If by overweight is meant an increase of bodyweight relative to height above the average for the species, then the following causes can be distinguished:

INCREASED LEAN BODY MASS (AS IS SEEN IN HYPERTROPHY OF MUSCLE INDUCED BY WORK, ACROMEGALY, ADRENOGENITAL SYNDROME)

If standard tables of height-weight relationship are used, many highly muscular individuals fall into the overweight group without being obese (Brožek and Keys, 1950). Moreover, the work of

Keys (1955, in press) and co-workers shows that athletic overweight individuals are almost invariably underfat compared with sedentary normal-weight subjects of the same height and age.

INCREASED INTERSTITIAL FLUID VOLUME (SUCH AS IS MET WITH IN CHRONIC OEDEMA AND MYXOEDEMA)

A form of spongy obesity, the Gilbert Dreyfus or paradoxical obesity, has been described by Leray (1951), in which the overweight is due largely to excessive fluid retention.

INCREASED BODY FAT¹

The deposits of fat may be localised, as in lipomatosis, lipodystrophy, lipomata, in the hereditary sex-linked steatopygia of Bushman and Hottentot women, or in Dercum's disease (*adiposis dolorosa* or painful nodular obesity), or it can be generalised, as in obesity proper or in general systemic lipomatosis. Accumulation of lipids other than triglycerides are seen in the Nieman Pick and Tay Sachs diseases (phospholipins), in Gaucher's disease (cerebrosides) and in the Schüller Christian syndrome (cholesterol and its esters). Obesity proper alone is covered in Table 1.

TABLE 1

TYPES OF OBESITY

<i>In mice</i>	
Genetic :	In yellow mice ; heterozygous, dominant character (Danforth, 1927 ; Kasten, 1952).
	Associated with hyperglycaemia ; homozygous, recessive character (Mayer, 1954).
Of hypothalamic origin :	Spontaneous (Vidal and de Robertis, 1943) or surgically induced (Mayer, French <i>et al.</i> , in press).
Of endocrine origin :	Caused by injection of pituitary tumours secreting adrenocorticotrophic hormone (Furth <i>et al.</i> , 1954).
Otherwise induced :	By treatment with gold thioglucose (Waxler and Brecher, 1950 ; Marshall and Mayer, 1954).
	By high-fat diet, C ₂ H and A strains (Fenton and Chase, 1951 ; Fenton and Dowling, 1953).
<i>In rats</i>	
Genetic :	Associated with diabetes (Sayers <i>et al.</i> , 1944).
Of hypothalamic origin :	Induced by bilateral (Hetherington and Ranson, 1940, 1942 ; Brobeck, 1946 ; Mayer, 1953c) or unilateral lesions (Mayer and Barnett, 1955).
Of other central nervous system origin :	From frontal lobe damage (Covian <i>et al.</i> , 1953).
Of endocrine origin :	From hypertrophy of adrenal cortical tissue (Bomskov and Schneider, 1939).
	From prolonged treatment with protamine zinc insulin (Mackay <i>et al.</i> , 1940) or insulin with forced feeding (Ingle and Mzamis, 1947).
	After thyroidectomy with hypothalamic lesions (Hetherington, 1943) or with forced feeding (Scow, 1951).
	From castration, in females (Holt <i>et al.</i> , 1936).
Otherwise induced :	By immobilisation (Ingle, 1949).
<i>In dogs</i>	
Genetic :	In the Shetland sheepdog, recessive character (Mayer, 1953a).
Of hypothalamic origin :	Spontaneous (Martin, 1953), surgically induced (Heinbecker <i>et al.</i> , 1944), or due to paraventricular degeneration caused by corticotropin or cortisone in excess (Heinbecker and Pfeifferberger, 1950).
Otherwise induced :	By immobilisation (Mayer, 1953a).
<i>In monkeys</i>	
Of hypothalamic origin :	Surgically induced (Brooks <i>et al.</i> , 1942).
Of other central nervous system origin :	Surgically induced by lesions of the thalamus (Ruch <i>et al.</i> , 1941).
<i>In farm animals</i>	
Genetic :	In strains selectively bred for fat, in particular, pigs bred for lard.
Of endocrine origin :	Induced by castration (Fish, 1925 ; Sellheim, 1913) and by oestrogens in the fowl (Bird, 1946) ; by castration and implants of oestrogens in male cattle.
Otherwise induced :	By immobilisation in pigs, cattle and geese ; by forced feeding in geese for production of foie gras (Wolfe <i>et al.</i> , 1952).

¹ Methods of estimating body fat have been excellently reviewed by Brožek and Keys (1950) and Keys and Brožek (1953).

TABLE 1—(contd.)

TYPES OF OBESITY

In man	
Genetic :	<p>A multiplicity of genes have been studied by Newman, von Vershuer, Bauer, Gurney, Rony, Angel and others, reviewed by Mayer (1953c).</p> <p>In congenital adipose macrosomia (Bauer, 1945).</p> <p>In monstrous infantile obesity (Jaso and Arbelo Curbelo, 1945).</p> <p>Associated with Laurence Moon Biedl syndrome (Bauer, 1945).</p> <p>Associated with <i>hyperostosis frontalis interna</i> (Bauer, 1945).</p> <p>Associated with von Gierke's disease.</p> <p>In familial hypoglycaemia (congenital lack of alpha cells) (McQuarrie <i>et al.</i>, 1950).</p>
Of hypothalamic origin :	<p>In <i>dystrophia adiposogenitalis</i>, with discrete or diffuse hypothalamic injury (Brain, 1947); occasionally with panhypopituitarism and narcolepsy (Mussio Fournier and Proto, 1947); Kleine Levin syndrome (Ronald, 1946).</p>
Of other central nervous system origin :	<p>After frontal lobotomy (Cobb, 1944; Rinkel <i>et al.</i>, 1947).</p> <p>In association with cortical lesions, in particular, bilateral frontal lesions (Kirschbaum, 1951).</p>
Of endocrine origin :	<p>With insulin-producing adenoma of the islets of Langerhans (Whipple, 1944), with diffuse hyperplasia of the islets, and in association with diabetes.</p> <p>With chromophobe adenoma of the pituitary without hypothalamic injury (Friedgood, 1950).</p> <p>In Cushing's syndrome (hyperglycocorticoidism).</p> <p>From treatment with cortisone or adrenocorticotrophic hormone.</p> <p>In the Bongiovanni Eisenmenger syndrome (Bongiovanni and Eisenmenger, 1951).</p> <p>In disorders of the reproductive system: gynandrim and gynism (Simpson, 1951), aspermatogenic gynaecomastia without aleydigism (Klinefelter <i>et al.</i>, 1942); male hypogonadism (sometimes with bulimia), postpubertal castration (Conn, 1944), menopause, ovarian disorder (Leray, 1951), paradoxical Gilbert Dreyfus disorder (Leray, 1951).</p> <p>In pseudohypoparathyroidism (Seabright Bantam syndrome) (Wolfson, 1954).</p>
Otherwise induced :	<p>In association with gout.</p> <p>By immobilisation in adults (Greene, 1939; Mayer, 1955<i>ab</i>, and children (Fry, 1953; Johnson <i>et al.</i>, in press).</p> <p>By psychic disturbance (Mayer, 1953c).</p> <p>By social and cultural pressure (Mayer, 1953c).</p>

The distinction between obesity and overweight is dramatically illustrated by experiments with mice with the obese-hyperglycaemic syndrome (Alonso and Maren, 1954). If such animals are restricted in their food intake over a long period, weight can be maintained within the normal range; under conditions of drastic energy restriction, their weight can be decreased to a level one-third below non-obese values. The fat content of normal-weight or underweight obese animals is still, however, much higher than normal, proportionally and even in absolute amount.

Excessive thinness usually results from losses of all three types of body constituents. The rare disease called histiodiuresis (Lawrence, 1946) and some cases of essential thinness may, however, be due to specific absence of fat. Recognition of the multiple etiology of excessive thinness has preceded that of the multiple etiology of obesity. Different types of cause for excessive thinness are summarised in Table 2.

TABLE 2

CAUSES OF EXCESSIVE THINNESS

Lack of Food or of Components of Food

Shortage of calories, with or without excessive physical work; shortage of protein, *e.g.*, in kwashiorkor; shortage of amino-acids (experimental); vitamin deficiencies, *e.g.* beriberi and pellagra.

Failure of Utilisation of Food

Gastro-intestinal disorders such as sprue and coeliac disease, pancreatic and liver disease which interfere with absorption.

Diabetes mellitus, thyrotoxicosis, progeria (Talbot *et al.*, 1945) in spite of high intake.

Pernicious anaemia and certain other forms of anaemia.

Failure of Appetite

From infections, poisoning, drugs (amphetamine, gossypol); hypothalamic anorexia, experimental (Anand and Brobeck, 1951*a*), *cachexia strumipriva* (Rony, 1940); panhypopituitarism, particularly Simmonds' disease; Addison's disease and pituitary Addison's disease, histiodiuresis (Lawrence, 1946); essential human thinness (Rony, 1940) and *anorexia nervosa*.

Carbohydrate Constituents

3175

KOWKABANY, G. N. **Paper chromatography of carbohydrates and related compounds.** *Advances in Carbohydrate Chem.*, 1954, **9**, 303-353. [Catholic Univ. America, Washington, D.C.]

3176

STRANGE, R. E., DARK, F. A. and NESS, A. G. **Interference by amino acids in the estimation of sugars by reductometric methods.** *Biochem. J.*, 1955, **59**, 172-175. [Dept. Microbiol. Res., Porton, Wiltshire.]

Interference by cystine, tyrosine and tryptophan in copper reduction methods is less than that in ferricyanide methods. A procedure is described in which cation exchange resins are used to remove amino-acids before the estimation of reducing sugars.—H. G. Bray.

3177

IWAINSKY, H. **Über den Einfluss von Aminosäuren auf die Bestimmung reduzierender Kohlenhydrate. [Effect of amino-acids on the estimation of reducing carbohydrates.]** *Ztschr. Lebensmittel-Untersuch. Forsch.*, 1955, **100**, 173-179. [Inst. Lebensmittelchem., Humboldt Univ., Berlin.]

Amino-acids interfere with methods in which copper reagents are used, but the Hagedorn Jensen and anthrone methods are little affected, the latter being the more reliable.—H. G. Bray.

3178

TURTON, C. N. and PACSU, E. **The effect of anion exchange resins on reducing sugars.** *J. Amer. Chem. Soc.*, 1955, **77**, 1059-1061. [Frick Chem. Lab., Princeton Univ., N.J.]

The passage of D-glucose or D-fructose through an Amberlite IRA-400 (OH-form) column resulted in small amounts of D-mannose. Conversely, D-mannose gave rise to D-glucose and D-fructose. Glucose, fructose and mannose produced in addition to D-fructose a ketose, apparently D-psicose (ribohexulose). Similar amounts of glucose, fructose and mannose were adsorbed on the column with equilibrium after 30 min. to 1 hr. The conversion of the resin to the carbonate form enabled the adsorbed sugars to be removed, but losses progressively increased after long periods of time and non-volatile acids were detected.—A. Hepburn.

3179

REYNOLDS, T. M. **Adsorption of glucose on a weakly basic anion-exchange resin.** *Nature*, 1955, **175**, 46-47. [Div. Food Preservation and Transport, C.S.I.R.O., Homebush, N.S.W.]

3180

DEVOR, A. W. **Cereal carbohydrate determination. Sulfonated 1-naphthol and anthrone reactions applied to sulfuric acid extract of cereals.** *J. Agric. Food Chem.*, 1954, **2**, 1290-1292. [Dept. Physiol. Chem., Ohio State Univ., Columbus, Ohio.]

Total carbohydrate in a 1.25 per cent. H_2SO_4 extract of cereals was simply and rapidly estimated by spectrophotometer after reaction with sulfonated 1-naphthol. Carbohydrate containing up to 14 per cent. pentose, calculated as xylose, could be measured with a glucose standard. By the study of the absorbance of glucose-xylose mixtures, graphs were obtained from which the percentage of pentose in cereal monosaccharides extracted could be calculated. Values ranged from zero in wheat and corn starches to 13.0 for oats. The different carbohydrate content found with the anthrone method, which measures hexose only, was used to confirm the pentose content.

A. Hepburn.

3181

BERNAERTS, J. **Dosage colorimétrique de faibles quantités de sucre interverti en présence de grands excès de saccharose. [Colorimetric estimation of small amounts of invert sugar in the presence of excess sucrose.]** *La Sucrerie Belge*, 1954, Nos. 7/8, pp. 7. [Lab. Central Minist. Affaires Econ., Brussels.]

The method of Caputto *et al.* (*Enzymologia*, 1948, **12**, 350) for the colorimetric estimation of monosaccharides in the presence of reducing disaccharide was successfully applied to the estimation of small amounts of invert sugar in the presence of excess sucrose. The sensitivity was much less in presence of phosphate ions.—A. Hepburn.

N.A. and R., July 1955

3182

WISE, C. S., DIMLER, R. J., DAVIS, H. A. and RIST, C. E. Determination of easily hydrolyzable fructose units in dextran preparations. *Anal. Chem.*, 1955, 27, 33-36. [N. Utilization Res. Branch, U.S. Dept. Agric., Peoria, Ill.]

Resorcinol and anthrone methods are described in which chromogenesis from glucose is much less than that from fructose. A qualitative chromatographic test for the detection of free or easily liberated fructose is described.—H. G. Bray.

3183

BULLASOVÁ, H. and HORÁKOVÁ, E. Kvantitativní stanovení glukosy v biologickém materiálu komplexometrickou metodou. [Quantitative estimation of glucose in biological material by a complexometric method.] *Chem. Listy*, 1954, 48, 1698-1700. [Biochem. Lab., Thomayer's Hosp., Prague.]

This is a new method for estimating glucose, based on the reduction of alkaline CuSO_4 and estimation of CuO dissolved in HNO_3 by microtitration with a complexone, with murexide as indicator.—M. Prokšová (Czechoslovakia).

3184

PRUNER, G. Micrometodo per la determinazione del glucosio in cm^3 0, 02-0, 10 di sangue con solfato di cerio n/2000. [Micro-method for the estimation of glucose in 0.02 to 0.10 ml. blood with 0.0005 N cerium sulphate.] *Rend. Ist. Super. Sanità, Rome*, 1954, 17, 123-128. French, English and German summaries.

In this method the sugar is oxidised with ferricyanide in heat at pH 10 and the resulting ferrocyanide is titrated with cerium sulphate, with o-phenanthroline ferrous sulphate complex as indicator. The recovery of 20 to 50 μg . glucose from 0.02 to 0.05 ml. blood was correct to ± 4 per cent.—D. Duncan.

3185

ROE, J. H. The determination of sugar in blood and spinal fluid with anthrone reagent. *J. Biol. Chem.*, 1955, 212, 335-343. [Dept. Biochem., Sch. Med., George Washington Univ., Washington, D.C.]

Precision was improved by previous mixing of anthrone and H_2SO_4 . When thiourea was added the reagent retained its chromogenic capacity for 2 weeks. The deproteinised filtrate from blood or diluted spinal fluid was mixed with the anthrone reagent, heated in a boiling-water bath for 15 min., and cooled, and glucose was estimated colorimetrically. In blood a considerable amount of carbohydrate, probably hexose diphosphate, was precipitated by a mixture of ZnSO_4 and $\text{Ba}(\text{OH})_2$, but not by tungstic or trichloroacetic acid. The

results compared favourably with those of the arsenomolybdate method of Nelson (Abst. 849, Vol. 14).—A. Hepburn.

Filter paper is used instead of a Gooch crucible for the separation of fibre remaining after treatment of material with a mixture of acetic and nitric acids.—H. G. Bray.

Nitrogenous Constituents

3188

ASSOCIATION OF OFFICIAL AGRICULTURAL CHEMISTS AND AMERICAN OIL CHEMISTS' SOCIETY JOINT COMMITTEE. Summary of the collaborative work on total nitrogen. *J. Amer. Oil Chem. Soc.*, 1955, 32, 35-36.

The results of collaboration between 27 laboratories in the estimation of total N in 10 different materials showed that as catalyst Hg was superior to Cu, which was therefore no longer recommended. Boric acid was inferior to standard acids for the absorption of ammonia. The time required for a burner to bring a sample of water to the boil varied widely between and within laboratories with both gas and electricity. From this the optimum digestion time, total times ranging from 55 min. to more than 3 hr., is considered still in doubt, although the best results were obtained with digestion times of 100 to 120 min.—A. Hepburn.

The separation of the protein components in 0.07-ml. samples of plasma by paper strip electrophoresis enabled the albumin: globulin ratio to be estimated by densitometer readings of the coloured spots. Actual amounts could be calculated from the total protein estimated by the micro-Kjeldahl procedure. Results were highly reproducible and agreed well with those of the usual chemical method.—A. Hepburn.

3192

COOPER, G. R. and MANDEL, E. E. (with OWINGS, R. H. and FETNER, J.) Paper electrophoresis with automatic scanning and recording. *J. Lab. Clin. Med.*, 1954, **44**, 636-643. [Commun. Dis. Centre, Pub. Health Serv., U.S. Dept. Health.]

The electrophoretically separated protein components of serum on filter paper strips were scanned automatically by combining a densitometer with an electrocardiograph to give typical electrophoresis curves. Values obtained from 12 normal sera differed slightly but significantly from those from the boundary method, albumin being 3.8 per cent. lower and γ -globulin 5.2 per cent. higher in the total protein. Electropherograms from 15 to 20 chromatograms could be recorded in one hour. Results were highly reproducible and could be used for recognition of abnormalities in the serum proteins due to disease.—A. Hepburn.

3193

BRATTSTEN, I. Continuous fractionation of serum by zone electrophoresis. *Acta chem. scand.*, 1954, **8**, 1947-1948. [Inst. Biochem., Univ. Upsala.]

Continuous fractionation of serum proteins was achieved by an arrangement by which veronal buffer was transported through a supporting medium in a direction perpendicular to the electric field. Distribution curves with 4 main peaks, α -, β - and γ -globulins and albumin, were formed. Fractionation of from 20 to 30 ml. serum provided sufficient material for analysis of these components.

ACKERMANN, P. G., TORO, G. and KOUNTZ, W. B. Zone electrophoresis in the study of serum lipoproteins. 1. Methods and preliminary results. *J. Lab. Clin. Med.*, 1954, **44**, 517-530. [St. Louis Chron. Hosp., Sch. Med., Washington Univ., St. Louis, Mo.]

After electrophoresis of serum in starch soaked with buffer the starch block was divided into thirty-six $\frac{1}{8}$ -in. sections and analysed for protein, P and cholesterol. Curves were obtained by plotting the amounts of cholesterol and phospholipin ($C \times 25$) against the number of the starch segment. Comparison with a similar curve for protein showed that in the normal human subject cholesterol and phospholipin had each 2 main similar fractions which migrated at about the same rate as albumin and β_2 -globulin and were identified as α - and β -lipoproteins. Curves from patients with different diseases are shown.—A. Hepburn.

3196

GOTTFRIED, S. P., POPE, R. H., FRIEDMAN, N. H. and DiMAURO, S. A simple method for the quantitative determination of alpha and beta lipoproteins in serum by paper electrophoresis. *J. Lab. Clin. Med.*, 1954, **44**, 651-654. [Dept. Biochem., Bridgeport Hosp., Bridgeport, Conn.]

Electrophoresis of serum followed by staining with Sudan III showed the separation into α - and β -lipoproteins. Curves were drawn by plotting optical density against the distance migrated. A serum protein curve used for fixing the position of the lipoprotein fractions indicated that the peak of the α -fraction lay between the α_1 -globulin and the albumin and the β -fraction lay between the γ - and β -globulins. An arbitrary quantitative estimation was obtained by measuring the area under the curve and values are at present being compiled.—A. Hepburn.

3198

SMITH, E. L. and TULLER, E. F. The paper chromatographic detection of the free sulfur-containing amino acids and small peptides in whole blood and serum. *Arch. Biochem. Biophys.*, 1955, **54**, 114-120. [Baker Clin. Res. Lab., New England Deaconess Hosp., Boston, Mass.]

The blood or serum is deproteinised by means of acetic acid and oxalic acid in the presence, when blood is used, of N-ethyl maleimide, which protects sulphhydryl groups. The protein-free supernatant is desalted by means of a resin column and the product is examined by paper chromatography. The solvents used for 2-dimensional chromatography are *n*-butanol, 40 per cent.; acetic acid, 10 per cent.; water, in the presence of 33 per cent. diethylamine, followed by *tert*-butanol, 10 per cent.; water, in the presence of 1 per cent. diethylamine. The detecting reagents are ninhydrin and, for sulphur compounds, a mixture of sodium azide and iodine.

Cysteine was found in whole blood, and new sulphur compounds in both blood and serum.

H. G. Bray.

3199

YEMM, E. W. and COCKING, E. C. The determination of amino-acids with ninhydrin. *Analyst*, 1955, **80**, 209-213. [Dept. Botany, Univ. Bristol.]

A procedure suitable for routine use is described which leads to a stoichiometric reaction between ninhydrin and most amino-acids. The reaction takes place in citrate buffer (pH 5) with a mixture of potassium cyanide, methyl Cellosolve and ninhydrin as reagent.—H. G. Bray.

3200

MOORE, S. and STEIN, W. H. A modified ninhydrin reagent for the photometric determination of amino acids and related compounds. *J. Biol. Chem.*, 1954, **211**, 907-913. [Labs. Rockefeller Inst. Med. Res., New York 21.]

The modified reagent contains 2 per cent. ninhydrin and 0.3 per cent. hydrindantin (reduced ninhydrin) in 3:1 methyl Cellosolve and 4*N* sodium acetate buffer. This stronger buffer with sodium acetate instead of sodium citrate eliminates preliminary adjustment of the pH of the effluent fractions. The direct addition of hydrindantin obviates the use of SnCl₂ as a reducing agent.

A. Hepburn.

3201

MOORE, S. and STEIN, W. H. Procedures for the chromatographic determination of amino acids

Vol. 26, No. 3

on four per cent. cross-linked sulfonated polystyrene resins. *J. Biol. Chem.*, 1954, **211**, 893-906. [Labs. Rockefeller Inst. Med. Res., New York 21.]

This is an improvement on the authors' original method (Abst. 4469, Vol. 21). A longer column, 150 cm., a resin with 4 instead of 8 per cent. cross-linkage and elution at pH 3.1 to 5 by sodium acetate-citrate buffers of gradually increasing pH and ionic strength enabled a mixture of 18 common amino-acids to be recovered in quantity within 3 per cent. of theory, except methionine, which had a constant loss of 10 per cent. Tryptophan and glutamine also were unstable. Basic amino-acids were eluted at pH 5 and no second column was required. Amino-acids and related compounds of plasma and tissue extracts can be estimated by this method; it can also be used to separate peptides.—A. Hepburn.

3202

HIRS, C. H. W., MOORE, S. and STEIN, W. H. The chromatography of amino acids on ion exchange resins. Use of volatile acids for elution. *J. Amer. Chem. Soc.*, 1954, **76**, 6063-6065. [Rockefeller Inst. Med. Res., New York.]

Aspartic acid, glutamic acid and tyrosine were isolated from an acid hydrolysate of bovine serum albumin by passage through a 30-cm. column of the strongly basic resin, Dowex 1- \times 8 in its acetate form, with 0.5*N* acetic acid as eluant. The remaining amino-acids were separated on a 150-cm. column of Dowex 50- \times 4 by elution with HCl gradually increasing from 1 to 4*N*. The recoveries from the latter column were quantitative, 70 per cent. for methionine. The recoveries of glutamic and aspartic acids were 85 and 70 per cent., respectively.—A. Hepburn.

3203

CAMPBELL, P. N., JACOBS, S., WORK, T. S. and KRESSMAN, T. R. E. Separation of amino-acids on columns of sulphonated polystyrene resins. *Chem. and Indust.*, 1955, No. 5, 117-118. [Nat. Inst. Med. Res., Mill Hill, London, N.W.7.]

Zeo-Karb ion-exchange resins were found satisfactory for the separation and estimation of amino-acids, with sodium citrate buffer as the eluant. The water regain value of the resin is important.

A useful guide to the genuineness of butter was the colour produced in the Tortelli Jaffe reaction (*Chem. Ztg.*, 1915, **39**, 24).—A. Hepburn.

3217

OSIŃSKA, Z. Porównanie trzech metod oznaczania zawartości tłuszczu w mięsie. [Comparison of three methods of estimating the fat content of meat.] *Rocz. Nauk. rol. [B]*, 1954, **69**, 71-77. Russian and English summaries.

The methods of Grossfeld, taken as standard, and Gerber, slightly modified, were equally accurate; results by Soxhlet's method were generally higher and the standard error was 4 times greater than in the other 2. The relatively high accuracy of Gerber's method and its usefulness for mass serial determinations was confirmed. (From summary.)—A. Hepburn.

3218

SHIPLE, W. F. Identification of fats by urea fractionation. *J. Assoc. Off. Agric. Chem.*, 1955, **38**, 156-165. [Dept. Dairy Indust., Cornell Univ., Ithaca, N.Y.]

Fatty acids prepared from pure and adulterated butterfats, oleomargarines, coconut oil, herring oil, whale oil, seal oil, cottonseed oil and soya bean oil were fractionated by complex formation with urea in methanolic solution. The refractive indices of the fractions were measured at 50° C.

By strictly adhering to the details of the procedure given, the refractive indices can be used as a guide to the identification of a particular fat and also as a means of quickly detecting grossly adulterated samples of butterfat.—G. A. Garton.

3219

CROMBIE, W. M. L., COMBER, R. and BOATMAN, S. G. The estimation of unsaturated fatty acids by reversed-phase partition chromatography. *Biochem. J.*, 1955, **59**, 309-316. [Dept. Botany, Univ. Southampton.]

The reversed-phase chromatographic technique of Howard and Martin (*Abst. 1353*, Vol. 20) was

applied to mixtures of saturated and saturated fatty acids. Although many unsaturated fatty acids were separable from one another, they were not usually separable from saturated acids. In order to estimate the amount of each unsaturated and unsaturated fatty acid in a mixture it was chromatographed before and after oxidation with alkaline KMnO_4 . The KMnO_4 degraded the unsaturated acids to products which were eluted more rapidly than myristic acid, so that the unsaturated acids could be estimated by difference.

The method was tested on several standard fatty acid mixtures and on the fatty acids from water melon, palm kernel, linseed and oiticica oils, with results which agreed well with analyses by ester-fractionation and spectrophotometric methods.

CHRISTIAN, K. R. and COUP, M. R. Measurement of feed intake by grazing cattle and sheep. 6. The determination of chromic oxide in faeces.

N.Z. J. Sci. Technol. [A], 1954, **36**, 328-330.
[Ruakura Animal Res. Stat., Dept. Agric.,
Hamilton.]

Chromic oxide in faeces ash was oxidised to dichromate by digestion with an aqueous mixture of phosphoric acid, manganese, sulphate and potassium bromate for 7 to 15 min. Any chromic oxide remaining dissolved in the solution and was oxidised by more bromate. The entire procedure took about 45 min. and 50 samples could be analysed simultaneously. Dichromate was estimated by reduction with arsenite and back titration with permanganate or by titration with ferrous ammonium sulphate. The reproducibility to within 2.5 per cent. was high and there was satisfactory agreement with the previous method (Abst. 2679, Vol. 23).—A. Hepburn.

3243

SALTZMAN, B. E. Microdetermination of cobalt in biological materials. *Anal. Chem.*, 1955, **27**, 284-287. [Div. Special Health Serv., U.S. Dept. Health, Cincinnati, Ohio.]

The material is ashed and the Co present is converted to its complex with 1-nitroso-2-naphthol, which is extracted with chloroform. The extract is purified with HCl and is ashed. Co in the residue is estimated by a nitroso R salt method.

H. G. Bray.

3244

JÉRÔME, H. and SCHMITT, H. Microméthode spectrophotométrique de dosage du cuivre total dans les tissus et liquides biologiques. [Spectrophotometric micro-method for estimating total copper in tissues and biological fluids.] *Bull. Soc. Chim. biol.*, 1954, **36**, 1343-1354. [Lab. Thérap., Fac. Méd., Paris.]

Two procedures are described, the first for use after treatment of the sample with HCl and trichloroacetic acid to liberate Cu and to precipitate protein and the second after wet ashing. Cu is estimated as its complex with 2:2'-diquinoline.

H. G. Bray.

3245

JANČIĆ, M. Une contribution à la méthodique du dosage du cuivre dans les liquides biologiques. [Estimation of copper in biological fluids.] *Acta med. jugoslav.*, 1954, **8**, 253-256. [Central Hemijiska Lab., Klin. Bolnice, Med. Fak., Sarajevo.] Serbian summary.

For clinical diagnosis an accurate method of estimating Cu in blood and urine is essential. Diethyldithiocarbamate is the reagent which it has been usual to employ but, since it gives the same colour with Fe as with Cu, Fe must be got rid of, which is a tiresome process. The reaction of Weehuizen (*Pharm. Weekbl.*, 1905, **42**, 271) is recommended in preference, and the technique is described in detail.—E. M. Hume.

3246

FABRE, R., TRUHAUT, R. and ROUQUETTE, A. Sur le microdosage du fluor dans les végétaux. [Micro-estimation of fluorine in plants.] *C.R. Acad. Sci.*, 1955, **240**, 226-229.

Incineration of a 5- to 10-g. sample in the presence of magnesium oxide and acetate, followed by treatment with sulphuric or perchloric acid with silica, allowed HF to be distilled off into 0.1 N NaOH. The distillate was acidified with HCl, brought to pH 3.5 with sodium monochloroacetate and titrated against thorium nitrate with sodium alizarin sulphate as indicator. The method was simple and sensitive to a few μg .—A. Hepburn.

MICROBIOLOGICAL

3268

HILL, H. Zur Methodik der mikrobiologischen Aminosäurebestimmung. [Technique of microbiological estimation of amino-acids.] *Arch. Tierernährung*, 1954, No. 5, Beihefte, 135-145. [Physiol. Inst., Tierärztl. Hochsch., Hanover.]

The bacteria used for estimation of threonine, valine, histidine and isoleucine were *Streptococcus faecalis* (lactis) R, for arginine, methionine, lysine, leucine and phenylalanine *Leuconostoc mesenteroides* (P 60), and for tryptophan *Lactobacillus arabinosus* 17-5 (ATCC 8014). The methods and basal media are fully described. The growth of the bacteria depends on the concentration of the limiting amino-acid when other requirements are met, and the degree of growth is measured by the pro-

duction of lactic acid and the shift in pH. The method can be used, for example, for amino-acids in hydrolysates of organic material or for free amino-acids in serum.—D. Duncan.

3269

HORN, M. J., BLUM, A. E., GERSDORFF, C. E. F. and WARREN, H. W. Sources of error in microbiological determinations of amino acids on acid hydrolysates. 2. Apparent loss of amino acids on storage. *Cereal Chem.*, 1955, **32**, 64-70. [Human Nutrit. Res. Branch, Agric. Res. Serv., U.S. Dept. Agric., Washington 25, D.C.]

Unfiltered acid hydrolysates of raw and cooked barley lost arginine, histidine, methionine, isoleucine, lysine and valine after storage for up to

N.A. and R., July 1955

2 months at pH 6.8 under toluene at room temperature. Leucine, phenylalanine and threonine were unaffected. No loss on storage occurred after filtration at pH 4.0. Only arginine, histidine and especially methionine in the unfiltered hydrolysates fell below the values obtained with filtration. Losses were apparently not due to bacterial

decomposition. The initial higher values in the unfiltered hydrolysates of valine, lysine, arginine and isoleucine were attributed to the activity of humin (see Abst. 945, Vol. 24).

Casein and whole barley hydrolysed in acid separately and together gave similar total amounts of the 9 amino-acids.—A. Hepburn.

3274

LJUNGGREN, H. Measurement of total body water with deuterium oxide and antipyrine. *Acta physiol. scand.*, 1955, **33**, 68-82. [Dept. Int. Med., Serafimerlasarettet, Stockholm.]

Deuterium oxide and antipyrine were infused intravenously, one after the other, into 2 healthy men. Total body water was estimated by both methods 7 and 8 times during 2 months. The coefficients of variation of the deuterium and anti-

pyrine spaces were 1.8, 2.0 and 5.6, 4.5 per cent., respectively. The greater variability of the antipyrine space was probably due to the larger error of 4 per cent. in the zero time concentration in the plasma; the equilibrium concentration of deuterium was about 1 per cent. The analytical error in the measurement of D_2O concentration by the gradient tube method was ± 0.0017 g. per cent.

The total fat excreted by patients on the usual hospital diet is measured over 3 or 4 days by methods which are described. In 11 normal subjects the mean daily fat excretion was 3.91 ± 2.45 g. as fatty acid; in 11 with steatorrhoea, 10.29 ± 4.49 g.—D. Harvey.

3277

PEETERS, H. and CALLENS, L. Une technique simple du test d'excretion d' I^{131} . (Test fonctionnel de la glande thyroïde.) [A simple technique for the I^{131} excretion test. (Functional test of the thyroid gland.)] *Rev. belg. Pathol. Méd. exp.*, 1954, **23**, 343-350. [Lab. Hôp. St. Jean, Bruges.]

A simple method of estimating the urinary excretion of a single dose of radio-active iodine is described. Between 15 and 20 $\mu C.$ of carrier-free I^{131} diluted in 50 ml. of distilled water were administered through a plastic straw while the recipient was fasting. The glass was rinsed with the same volume of water and this also was swallowed. Urine samples were collected in litre bottles 5 times in the next 48 hr., with 6 hr. between the

first 2 collections and 12 hr. between the other 3. The volumes were made up to the litre mark and the radio-activity was measured with a scintillating counter. Comparison was made with a bottle containing a dose of ^{131}I equal to the amount ingested, diluted to the same volume and kept for the same length of time. Several possible causes of error, such as the presence of salt or glucose in the urine, were examined and found to be of slight significance. It is claimed that this technique is simple and accurate.—B. W. Simpson.

3278

SINGLETON, W. S. and BENERITO, R. R. **Surface phenomena of fats for parenteral nutrition.** *J. Amer. Oil Chem. Soc.*, 1955, **32**, 23-25. [S. Reg. Res. Lab., New Orleans, La.]

The surface tensions and interfacial tensions (against water) of crude and purified groundnut, cottonseed, rice bran and olive oils, of purified coconut and sesame oils and of crude pecan oil were measured.

On the basis of surface phenomena it is concluded that the crude oils could be more easily emulsified than the refined oils, though the physiological effects in parenteral nutrition of the non-glyceride material in the crude oils are not known.

3279

AHRENS, E. H. (Jr.), DOLE, V. P. and BLANKENHORN, D. H. **The use of orally-fed liquid formulas in metabolic studies.** *Amer. J. Clin. Nutr.*, 1954, **2**, 336-342. [Hosp., Rockefeller Inst. Med. Res.] Spanish summary.

Details are given of the preparation and composition of 3 basic mixtures which, in the authors' experience, have proved to be the most useful for administration by stomach tube. The first provided 1.25 Cal. per g. and contained 22 g. maize, cottonseed or coconut oil, 37.5 g. Lesofac and 41.5 g. dextrose with water to make 400 g.; the second also provided 1.25 Cal. per g. and consisted of 25 g. frozen egg yolk, 18 g. unsalted butter, 30 g. Lesofac and 41.5 g. dextrose with water to make 400 g.; the third provided 1.5 Cal. per g. and consisted of 12.5 g. maize oil, 175 g. evaporated milk and 34.5 g. dextrose with water to make 333.3 g.

Thirty patients were given these diets for as long as 16 weeks without ill effect. Twelve dogs took them well for 2 to 10 weeks and maintained or gained weight. Advantages of the diets are constant composition, economy and ease of preparation; also, a few mixtures meet the needs of several different metabolic studies.—G. F. Garton.

3280

PEARSON, E., BALIKOV, B. and REISS, E. **An analysis of errors contributed by the diet in**

metabolic studies. *Metabolism*, 1955, **4**, 29-38. [Surg. Res. Unit, Brooke Army Med. Centre, Fort Sam Houston, Tex.]

In a long metabolic experiment on burned patients storage space was limited, so that one batch of food was sufficient for only 6 to 8 weeks. When all of one or more foods from a batch had been served the rest was not used and the 3 menus served were prepared from a new batch of foods. Three to 5 samples of each menu were prepared for analysis from 9 batches of food. Samples were analysed for N, Ca, P, Mg, K, Na and Cl.

Significant differences between batches were found in all constituents except K. In a particular batch of food a large variation due to non-analytical errors was noted. Consistent changes of composition during storage were not found. The mean analytical composition of each menu differed considerably from the composition calculated from standard tables of food composition.

In this apparatus plastic replaces glass in almost all parts which are strong, separable and easily replaceable. It is possible to perfuse with blood. Only small organs have been used; they can be kept under constant microscopic observation and in position for photography.—A. Hepburn.

3287

COLUMBUS, A. Stickstoff-Grundumsatz und Methodik der Bestimmung der biologischen Eiweisswertigkeit nach dem N-Bilanz-Verfahren bei wachsenden Ratten. [Endogenous nitrogen metabolism and methods for estimating the biological value of protein by the N balance technique on growing rats.] *Arch. Tierernähr.*, 1954, No. 4, Beihefte, 51-82. [Inst. Tierernähr., Humboldt Univ., Berlin.]

Nitrogen balances under carefully controlled conditions were studied with genetically homogeneous groups of rats from 5 or 6 weeks of age until growth was almost completed.

N-free diet was used to study endogenous urinary N, which can be expressed as a function of bodyweight, as can the endogenous faecal N. Equations are given which show how the biological value of different proteins was related to the protein intake and the endogenous N turnover. Skimmed milk, meatmeal, yeast and bean proteins, and also 2 kinds of sweet lupin protein, were compared.

D. Duncan.

3288

COLUMBUS, A. Der Stickstoff-Grundumsatz bei wachsenden Kaninchen, und eine Bilanz-Methodik zur Bestimmung der biologischen

Eiweisswertigkeit. [Endogenous nitrogen metabolism in growing rabbits and a balance method for estimating the biological value of protein.] *Arch. Tierernähr.*, 1954, No. 5, Beihefte, 146-165. [Inst. Tierernähr., Humboldt Univ., Berlin.]

The method resembled that for rats (preceding Abst.). Three breeds of rabbit were used. The pre-period on N-free diet was 7 days, with estimation of endogenous N excretion on the last 2. The relations between urinary and faecal N losses and bodyweight are plotted and expressed in formulae. The use of the method to compare the biological values of several soya bean and lupin proteins is described.—D. Duncan.

3289

NEHRING, K. (with HAESLER, E.) Untersuchungen über die biologische Wertigkeit von Eiweissfuttermitteln. 1. Die Bestimmung der biologischen Wertigkeit und der Ergänzungswirkung von Eiweissfuttermitteln durch Versuche an wachsenden Ratten. [Biological value of protein feeds. 1. Estimation of the biological and growth values of protein feeds by studies on growing rats.] *Arch. Tierernähr.*, 1954, No. 5, Beihefte, 110-126. [Oskar Kellner Inst. Tierernähr., Rostock.]

The technique was that described by Columbus (Abst. 3287). The intake for rats of 80 to 170 g. was constant at 10 g. dry substance per rat daily. The estimation of N metabolism in the pre-period of 4 days on the N-free basal diet is described and formulae are given. The optimum protein intake was estimated to be 1.5 mg. N daily or 9.38 per cent. total protein. Controls in each study received this quantity of skimmed milk protein.

The technique was used to study the value of adding methionine to food yeast protein. The mean biological value of yeast protein was 66.7, and with added methionine 78.97. The mean weight changes in 5 days on these proteins were -1.3 and +5.0 g. In a second experiment the mean biological values of yeast alone or with methionine or penicillin were 44.85, 69.8 and 50.15 and the weight changes -3.55, +2.9 and -2.0 g. The values of yeast and sesame meal together and separately were compared also.—D. Duncan.

A stainless steel trocar and cannula with attached syringe are used. The technique is described in detail. Biopsies have been performed successfully on 64 cattle, ranging in age from 3 days to 12 years, with no ill effect. The average weight of tissue obtained is 1 g.—W. A. Greig.

3294

- TORELL, D. T. **An esophageal fistula for animal nutrition studies.** *J. Animal Sci.*, 1954, 13, 878-884. [Univ. California.]

A method of making an oesophageal fistula in sheep is described. The principal difficulty is in keeping the fistula closed when not in use; attempts to do this are described. The technique was used successfully in one animal to collect pasture eaten while the animal grazed.

A. T. Phillipson.

3295

- BOUCKAERT, J. H. and OYAERT, W. **A method of collecting fluid leaving the omasum of sheep.** *Nature*, 1954, 174, 1195. [Vet. Coll., Ghent.]

A funnel-shaped cannula which can be placed inside the abomasum of sheep and which is fitted with a side arm which protrudes through the abomasal and abdominal wall is described. The wide mouth of the cannula is fixed underneath the omaso-abomasal orifice. When in use the lower end of the funnel is closed with a balloon so that fluid passing from the omasum flows to the exterior through the side arm. Fluid obtained in this way contains more chloride than rumen fluid,

and pepsin may be present in traces. The pH is usually higher than that of the rumen and the dry matter content varies from 5 to 10 per cent. Reticulum and rumen movements remain normal.

A. T. Phillipson.

- CHANG, W. Y., COUCH, J. R., LYMAN, C. M., HUNTER, W. L., ENTWISTLE, V. P., GREEN, W. C., WATTS, A. B., POPE, C. W., CABELL, C. A. and EARLE, I. P. **The nutritional value of prepress-solvent cottonseed meals.** *J. Amer. Oil Chem. Soc.*, 1955, 32, 103-109. [Texas Agric. Exp. Stat., College Station.]

The nutritional value of pre-press cottonseed meals was studied in 4 different laboratories by different animal methods. In chick feeding trials, one group gave the meals at 50 per cent. of the ration from day old to 4 weeks. A second group included the meals so as to provide 20 per cent. crude protein and these rations were given from 14 to 22 days. A third group tested the supplementary value of the meals by giving them to chicks which had been reared for 10 days on a ration of yellow maize meal fortified with vitamins and minerals. The cottonseed meals were then included in rations which were given for 2 weeks, so that they contributed 6 per cent. of the crude protein, maize meal providing another 6 per cent. A fourth group of workers used a rat repletion method.

In all studies a better prediction of protein quality was given by the amount of N soluble in 0.02 N NaOH than by that soluble in NaCl. The amount of total gossypol in these particular meals was also a good guide to protein quality. The first group of workers found that the best meals gave better growth results than soya bean meal.

D. H. Shrimpton.

WOELKE, M. Die Anwendung der Grosszahl-Forschung und Häufigkeitsanalyse in einem Geflügelversuch. [Use of large samples and frequency analysis in a poultry experiment.] *Arch. Geflügelk.*, 1954, **18**, 264-271. [Inst. Tierzucht, Justus Liebig Hochschule, Giessen.] English and French summaries.

The weight of hen's eggs is investigated with 3627 eggs, produced by 19 hens, the data being treated as if they were independent. First an analysis of all the eggs is made, then of the yield of 18 hens, and also of the other hen. The results obtained by numerical methods (mean and standard deviation) are compared with those obtained by the use of probability paper. In addition, a numerical measure of skewness is obtained, but in the graphical method it is indicated only by a systematic deviation from linearity of the cumulative percentage curve.

The relative merits of conventional methods of analysis and of the use of probability paper with large samples are discussed; the conclusion is that although the method to be employed is a matter for personal choice, the former are generally preferable.—A. W. Boyne.

Acidity and temperature are the most important conditions. The fermenting agent should be fresh. Yeast of the *Torula* type and lactic acid bacteria (*Bact. bulgaricum* type) are used. The optimum temperature for yeast fermentation is about 30° C. and for *Bact. bulgaricum* 40° C. It is important to maintain the correct temperature throughout the process. Acidity during the autumn and winter period should be up to 50° Turner during the fermentation process.

KREMER, YU. N. Vliyaniye sernistogo gaza na sokhranyaniye triptofana pri kislotnom gidrolize belkov. [The effect of sulphur dioxide on the conservation of tryptophan in the acid hydrolysis of proteins.] *Dokl. Akad. Nauk S.S.S.R.*, 1954, 98, 627-628.

The proteins used were freshly washed fibroin and casein, which were brought into solution by digestion with pepsin. Twenty ml. of the solution was placed in 100 ml. Kjeldahl flasks and saturated cold with sulphur dioxide for 10 min. Sufficient concentrated sulphuric acid was poured into each flask to bring the content up to 2, 4, 6, 8 or 10 per cent. The flasks were corked with cotton-wool and autoclaved for 3 hr. at 1 atm. and 120° C. The hydrolysates were then transferred to measured 200-ml. flasks. Total N was estimated in the hydrolysates by the micro-Kjeldahl method, amino-N by the method of Pope and Stevens and tryptophan by the method of Hopkins and Winkler. As control the hydrolysis was performed under the same conditions without saturation with SO₂.

By this method almost all the tryptophan is conserved but it is possible that other amino-acids are destroyed. Hydrolysates with 2 and 4 per

cent. acid are almost colourless; with the usual method of acid hydrolysis the products are usually dark brown.—H. Scherbatoff.

3309

CLARK, H. E., WILMETH, M. C., HARRISON, D. L. and VAIL, G. E. The effect of braising and pressure saucepan cookery on the cooking losses, palatability, and nutritive value of the proteins of round steaks. *Food Res.*, 1955, 20, 35-41. [Dept. Foods Nutrit., Kansas State Coll., Manhattan.]

Cooking losses, press fluid and shear value were ascertained for paired top and bottom round steaks from 3 U.S. commercial grade carcasses, braised to an internal temperature of 176° F. (80° C.) in a gas oven or cooked in a pressure cooker at 10 or 15 lb. pressure to 176° F. or at 15 lb. pressure to 234° F. (112-2° C.).

The results were analysed statistically and showed that the temperature to which the meat was cooked, and not the cooking method, was crucial; meat cooked to 176° F. lost less weight and was better for aroma, flavour and juiciness than meat cooked to 234° F., but was less tender.

Samples of the cooked and raw meat, ground, dried and extracted with ether, were incorporated for 4 weeks in the diet, fed to appetite, of groups of 8 to 10 weanling male Sprague Dawley rats to provide 1.6 or 2 per cent. N, the rest of the diet being Crisco 20, Ruffex 2, salt mixture 5, vitamin mixture 5 and dextrin to 100. Food intake, weight gain, urinary and faecal N and liver and carcass N were estimated.

There was no evidence of impairment of the nutritive value of the meat proteins by any of the methods of cooking. It was concluded also that although rats on the 2 per cent. N diet retained more N, under the conditions of the experiment the diet with 1.6 per cent. N was as useful for the comparison of nutritive values of beef cooked in different ways.—W. M. Deans.

3310

NIINIVAARA, F. P., DUROCHMAN, E. and VARTIOVAARA, U. An improved processing of dry sausage by means of bacterial pure cultures. *Acta agral. fenn.*, 1955, 83, 230-237. [Res. Lab. Meat Producers, Hämeenlinna, Finland.] Finnish summary.

When a harmless nitrate-reducing micro-organism resembling *Micrococcus aurantiacus* (Schroeter) Cohn, isolated from processed meats, was added to dry (raw smoked) sausage at the rate of 50×10^6 cells per kg. mix, the colour developed more rapidly, so that the manufacturing time could be cut down from 14 to 9 days, and spoilage by putrefactive bacteria did not occur.

Four processes were compared: flame drying (2 methods), hot-air, steam and vacuum drying with meal and press cake. The meals were re-examined after 3 and 12 months. Herring oil usually contains 50 to 100 I.U. vitamin A per g. Flame-dried meal had none and meal dried by hot air lost in store what was left. Steam drying preserved vitamin A and there was little oxidation in storage. After vacuum drying vitamin A could not be estimated by the Carr Price method. Rancidity was inversely related to vitamin A content. There was no change in free fatty acids during drying or subsequent storage, and choline was not affected. Roughly half the ammonia N was lost during drying. Digestibility of the protein *in vitro* was not related to the method of drying.

SOLA, E. Metoder for foredling av fiskeavfall. [Processing fish waste.] *Fiskeridirektoratets Skr. Ser. Teknol. Undersøk.*, 1954, 3, No. 1, pp. 48. English summary.

In this lecture the production of fishmeal in Norway is described. The raw materials in 1951 were approximately 7000 tons of white fish and 4000 tons of fat fish waste. The "old" method, with preliminary boiling and pressing, and so with loss of at least 20 per cent. of dry matter, is now little used. The Schlöterhose method with vacuum drying followed by drying in steam-heated drums is excellent but costly. The Vega method, which avoids the need for boiling or vacuum drying by mixing half-dry with fresh material in the first stage,

Vol. 25, No. 3

produces a whole meal (see Abst. 3364, Vol. 25) of excellent quality if the oven drying is correctly managed. A modification of this method, in which a press to remove fat is introduced between the first and second stages, is used for fat fish waste. Several other methods are described, with costs in fuel and power.—I. Leitch.

A study of the differences in composition between whole grain and the processed form of different cereal foods, and the effect of variations in certain details of preparation on these differences, with an account of the applications of the work on a commercial scale.—D. W. Taylor.

3318

WAGER, H. G. The browning reaction in dehydrated carrot and potato: its initiation and the separation and partial characterization of an intermediate from dehydrated carrot. *J. Sci. Food Agric.*, 1955, 6, 57-64. [Low Temp. Res. Stat., Univ. Cambridge.]

The substances responsible for the browning reaction in dehydrated carrot were soluble in water and ethanol. The basic, acidic and neutral fractions obtained from ethanol extracts of carrots or potatoes by ion-exchange chromatography were heated separately and in all combinations. Considerable browning occurred only when both basic and neutral fractions were present. A colourless intermediate of the reaction which occurred slightly in the basic fraction heated alone was isolated and appeared to be an isoglycosylamine.—A. Hepburn.

3319

KUPPERMAN, R. P. and KARON, M. L. Effect of time and temperature of storage on the free and total gossypol content of cottonseed meals

and of mixed diets. *J. Amer. Oil Chem. Soc.*, 1955, **32**, 54-57. [S. Reg. Res. Lab., New Orleans, La.]

A study was made of the effects of duration and temperature of storage on the free and total gossypol contents of cottonseed meals, some with added gossypol, and of diets to which gossypol had been added. There was no change in free or total gossypol content during storage in commercially prepared meals, but in all others there was a decrease of free gossypol. In the diets there was also a decrease of total gossypol. These changes were more marked when the temperature was raised to 37.5° C. or to 60° C. for 90 days. It is not known whether the gossypol is destroyed or not.—D. H. Shrimpton.

3320

PONS, W. A. (JR.), THURBER, F. H. and HOFFFAUT, C. L. Prepress-solvent extraction of cottonseed, processing conditions and characteristics of products. *J. Amer. Oil Chem. Soc.*, 1955, **32**, 98-103. [S. Reg. Res. Lab., New Orleans, La.]

Free gossypol and N soluble in 0.5 M NaCl were estimated in samples of meal and oil drawn at different stages of processing in 11 mills where the cottonseed undergoes a screw-pressing process before solvent extraction. The free gossypol content of the meals was reduced during cooking, when some gossypol appeared to be bound to some constituents of the meal; and during pre-pressing and solvent extraction, when more gossypol was removed in the oils which separated. The greatest reduction in N soluble in 0.5 M NaCl also occurred during cooking, changes in subsequent stages of the process being slight.

D. H. Shrimpton.

3321

SPRENGER, J. J. I. and DIJKSTRA, N. D. The effect of drying temperatures on the quality of the product in dehydrating grass. *European Grassland Conference, Paris*, June 1954, pp. 11.

High-temperature grass driers (air temperature at inlet above 200° C.) had been found to cause losses of 15 per cent. of the digestible crude protein content of fresh grass, low-temperature driers lost 5.3 per cent. The high-temperature product is not now inferior, standards of management having improved. Oil-firing allows greater control than coke, particularly over outlet temperature, which should be as low as possible.—J. L. Corbett.

3322

COWAN, R. L., BRATZLER, J. W. and SWIFT, R. W. Grass silage preservation with sodium bisulfite. *Pennsylvania Agric. Exp. Stat. Prog. Rep.* No. 99, April 1953, pp. 10. [State Coll., Pa.]

Cocksfoot and alfalfa-bromegrass mixture were ensiled with powdered sodium bisulfite at the rate of 8 lb. per ton of green matter. A simple automatic method of adding the bisulfite, adapted from a fertiliser spreader, is described. Provided un wilted crops are used good silage can be made easily and safely. The experimental silages reported compared well with similar crops ensiled with molasses or without preservatives in appearance, odour, composition and digestibility. In simple palatability trials 2-year-old heifers ate 3 times as much alfalfa silage made with sodium bisulfite as they did of alfalfa silage made with SO₂ or without preservative.—T. D. Bell.

3323

DIJKSTRA, N. D. Proefnemingen over ensilieren van gras met Kofa-zout en albumex. [Experiments in ensiling grass with Kofa salt and Albumex.] *Versl. Landbouwk. Onderzoek.*, 1954, No. 60.5, pp. 26. English summary.

Kofa salt is a mixture of 20 parts calcium formate and 3 parts sodium nitrite; Albumex is a mixture of 1 part each of aluminium formate and sodium nitrate with 3 parts NaCl. Two experiments were made with each. Neither produced any improvement in quality of silage and the slight reduction of losses by Kofa salt was too small to be of significance.—I. Leitch.

3324

POLJÄRVI, I. A.I.V., Calcifor- ja Kofa-menetelmän vertailu-kokeita. [Comparative experiments with the A.I.V., Calcifor and Kofa methods of making silage.] *Acta agral. fenn.*, 1955, **83**, 173-184. [Maatalousk. Kotieläinhoito-osasto, Tikkurila.] German summary.

Clover and timothy were ensiled by the A.I.V., Calcifor and Kofa methods or without addition. Conservation of nutrients, quality and digestibility were best with the A.I.V. method; next came the Calcifor and Kofa methods, the results of which were much the same and superior to those without addition.

Autumn rape was ensiled by the A.I.V. and Kofa methods and again the A.I.V. method proved superior. (From summary).—W. M. Deans.

3325

ISAJEV, F., FRANZ, J. and NOVÁK, J. Výsledky pokusů se silážováním vojtěšky a vojtěško-travní směsky bez přidavku konzervačních přísad. [Experimental results of making silage of lucerne and lucerne-grass mixtures without preservatives.] *Šborn. čsl. Akad. Zvěř.*, 1954, **27**, 501-516. Russian and English summaries.

Alfalfa silage was made from wilted crops without the addition of molasses. Laboratory

N.A. and R., July 1955

tests were first made to establish the limits of wilting for good silage. It was found that the dry matter of the crop should not exceed 50 to 55 per cent.

Compared with hay, silage made with wilted crops always had greater losses of nutrients, because of the losses at the edges even in good silos. Moulds grew more quickly than lactic acid bacteria, because in the semi-dry crop poor compaction meant that there was too much air. The addition of a small quantity of molasses prevented this.

To avoid complete loss when haymaking is impossible, the dried crop can be ensiled, but it is better to add a little molasses, or to ensile the young green alfalfa with 25 per cent. straw. (From summary.)—T. D. Bell.

3326

BARTOŠ, S. Hodnocení siláží s vysokým obsahem sušiny. [Classification of silages with a high content of dry matter.] *Sborn. ěsl. Akad. Zěměd.*, 1954, 27, 525-530. Russian and English summaries.

When the Skorpik method is used, silage of high dry matter content may be wrongly classified because of its high pH value. It was found that the ammonia content is a better measure of the quality of such silage. (From summary.)

T. D. Bell.

3327

ŠALOVÁ, J. Ověření nejvhodnějších dávek mazu ze škrobnatých krmiv k silážování zelené píce. [The most suitable addition of steamed starch-containing feeds to silages of green fodder.] *Sborn. ěsl. Akad. Zěměd.*, 1954, 27, 563-574. Russian and English summaries.

Laboratory and field experiments were made. They showed that when silage was made from crops rich in protein, 2 per cent. molasses could be replaced by 1.75 per cent. steamed bruised maize, 2 per cent. steamed ground barley, 7.5 per cent. steamed potatoes or 1.25 per cent. dry potato flakes. Smaller amounts gave inferior silage, but greater amounts had no advantage. Unsteamed grains were of no use. The method of steaming was to leave the grains for 2 to 3 hr. in twice their volume of water at 50° to 70° C. (122° to 158° F.). This method of ensiling was not successful with alfalfa of high dry matter content. (From summary.)—T. D. Bell.

3328

Nový, O. Klasifikační tabulka silážních pícnin podle obsahu cukru a cukerného minima. [A table classifying silage crops by their sugar content and the minimum content of sugar

Vol. 25, No. 3

required.] *Sborn. ěsl. Akad. Zěměd.*, 1954, 27, 575-584. Russian and English summaries.

Nine hundred and sixty-eight samples of different feeds were analysed and the results are tabulated, showing the sugar content and the amount of sugar it is necessary to add for silage making. By the use of these tables it is hoped to avoid waste of molasses and, on the other hand, the risk of spoiling the silage. The tables were tested on 28 occasions and found reliable. (From summary.)—T. D. Bell.

3329

KREULA, M. On the content of butyric acid and butyric acid bacteria in silage. *Acta agral. fenn.*, 1955, 83, 238-243. [Lab. Valio, Helsinki.]

Good silages free from butyric acid were prepared by the A.I.V. method from sugar beet tops, turnips with tops, and clover and timothy. A positive correlation was found between pH, butyric acid and the number of butyric acid bacteria. Butyric acid fermentation depended closely on pH and above pH 4 was not inhibited. The quality of silage was adversely affected by a high fibre content even when pH was satisfactory.

BLACK, W. A. P. The preservation of seaweed by ensiling and bactericides. *J. Sci. Food Agric.*, 1955, 6, 14-23. [Inst. Seaweed Res., Inveresk, Midlothian.]

Laboratory and pilot scale experiments were made. When sea water with 20 per cent. NaCl added was used the seaweed was preserved, but there were major changes in composition and loss of nutrients. The addition of bactericides to sea water in sufficient quantity for preservation killed the seaweed also. Good preservation was obtained by treating the seaweed with sulphur dioxide and excluding air.

Seaweed ensiled without any addition gave a good lactic acid fermentation. The conservation of the nutrients depended on the original composition of the seaweed and therefore on the season at which it was harvested. Digestibility trials were proposed but could not be made because sheep of the breed available would not eat the silage.

CULTURE OF MICRO-ORGANISMS FOR FOOD

3332

MURRAY, S., WOODBINE, M. and WALKER, T. K.
Microbiological synthesis of fat. The formation of fat from sucrose. *J. Exp. Botany*, 1953, 4, 251-256. [Div. Indust. Biochem., Fac. Technol., Univ. Manchester.]

In all 43 strains of moulds, representative of 10 species, were cultured for 14 days at 25° C. on 4 media containing inorganic salts and sucrose. The weights of mycelia and their fat content were estimated.

The highest yields of mycelium were produced by *Penicillium javanicum*, van Beyma, *P. soppi*, Zaleski and *Aspergillus nidulans*, Eidam. The highest fat contents (based on mycelial weight) were produced by *P. soppi*, 34.8 per cent., *Fusarium lini*, 28.4 per cent., and *A. nidulans*, 25.8 per cent. Other moulds giving results showing promise for further study included *Penicillium spinulosum*, *P. aurantiobrunneum*, *P. oxalicum*, *Fusarium graminearum*, *F. oxysporum*, *Aspergillus flavus* and *A. clavatus*.—G. A. Garton.

FOODSTUFFS OF ANIMAL ORIGIN

General

3337

FREDHOLM, H. Threonine in foods of animal origin. *Acta Agric. scand.*, 1954/55, 5, 11-22. [Res. Lab. Dept., Sveriges Slakteriförbund, Stockholm.]

Threonine was estimated chemically and microbiologically in different kinds of meat, milk, some products related to these, cheese and *Torula utilis* protein. Free threonine was found in ripe Gouda, Herrgård and Cheddar cheese. The amounts diminished during ripening. Autoclaving, roasting or boiling of beef, pork or *Torula utilis* protein diminished hydrolysable threonine; autoclaving in presence of soluble carbohydrates had the greatest effect. The losses were greater when measured microbiologically by *Streptococcus faecalis*, which is specific for L-threonine.

ZILLIKEN, F., BRAUN, G. A. and GYÖRGY, P. Gynaminic acid. A naturally occurring form of neuraminic acid in human milk. *Arch. Biochem. Biophys.*, 1955, 54, 564-566. [Dept. Biochem., Sch. Med., Univ. Pennsylvania, Philadelphia.]

The fractions from the non-dialysable portion of deproteinised human milk which were precipitable with 60 to 87 per cent. ethanol possessed the

N.A. and R., July 1955

highest growth activity for *Lactobacillus bifidus* var. Penn (see Absts. 1617, 3509, Vol. 24). Hydrolysis with 0.05 N H₂SO₄ for 1 hr. at 80° C. did not destroy this activity. From the ethanol-precipitable material 3 fractions were isolated by ion-exchange chromatography. From one of these a new acid called gynaminic acid was crystallised. Treatment with methanol and HCl and N-deacetylation with Ba(OH)₂ converted it to methoxyneuraminic acid. Mild hydrolysis of the other 2 fractions released gynaminic acid and further hydroxylis fucose, glucose, galactose and glucosamine. The dialysable portion of the growth substance in milk showed a similar pattern on chromatography; one of the 2 acid fractions found was apparently gynaminic acid. Gynaminic acid was considered to be a naturally occurring form of neuraminic acid and a component of the growth substance.—A. Hepburn.

3339

PALOHEIMO, L., HERKOLA, E. and MÄKELÄ, A.
Studies on the composition of cow's milk.
Acta agral. fenn., 1955, **83**, 113-124. [Dept. Animal Husbandry, Univ. Helsinki.]

The first part of this paper is a study of the variations in the composition of the milk of 14 Ayrshire cows under constant conditions indoors during 19 five-day periods when their milk yields were almost constant. The data were collected in the years 1936 to 1938. They are tabulated for each cow.

For most of the cows the percentage deviation of protein from the mean was less than 5 and that of sugar less than 6. Ash was more variable, and fat most variable, the variation exceeding 10 per cent. for 2 cows. These findings are similar to those of Kühn *et al.* (*J. Landwirtsch.*, 1874, **22**). The protein content and energy value of the milks were in good agreement with those calculated from the formula of Poijärvi and Listo (*Valt. maatalouskoet. julk.*, 1930, **28**).

The second part gives a preliminary account of experiments in progress on the effect of feed deprivation. Results are presented for 8 cows which for 3 days were given a maintenance ration of timothy hay only; before and after, they were fed according to requirement.

Milk yield fell abruptly, especially in high-yielding cows. Protein and sugar contents were reduced but fat content rose considerably; changes in ash content were slight. Recovery from the effects of feed deprivation took several days.

W. M. Deans.

3340

SEEKLES, L. and SMEETS, W. T. G. M. L'instabilité du lait par suite d'une augmentation de la teneur en ions de calcium. [**Instability of**

milk following an increase in calcium ion content.] *Lait*, 1954, **34**, 610-627.

The authors' own investigations of the cause of the "Utrecht abnormality" are reviewed with special reference to the method devised for the estimation of Ca ions in milk (see Absts. 4240, Vol. 17; 1289, Vol. 23). The treatment of cows producing such milk while on a rich diet is to give 50 or, if necessary, 100 g. sodium citrate daily by mouth for a few days; 30 g. given by subcutaneous injection may also be effective. Stabilisation of milk in bulk can readily be brought about by adding a small amount of sodium citrate.

D. Harvey.

3341

TASKER, N. **The recorded butterfat content of bulk milk from a herd of White Fulani cattle.** *J. Dairy Res.*, 1955, **22**, 16-21. [Dept. Local Indust., N. Nigeria.]

Fat was estimated daily throughout 1950 by the Gerber method in bulked morning and evening milk from some 50 White Fulani cows at the Livestock Improvement Centre at Vom, which is about 4000 ft. above sea level and has a mean rainfall of about 55 in., three-quarters of it in summer. From December to April grazing is supplemented with grain, hay and silage. There were 91 cows in the herd; the mean milk yield per cow per annum was 1437 lb., and the mean 305-day yield 1407 lb., but the mean lactation period was only 256 days.

Fat percentage averaged over the year was 6.39; for morning milk 6.29, evening 6.56. The considerable seasonal variations could not be related to changes in humidity. The fat percentage was highest and least variable when maximum day temperature was lowest and the difference between day and night temperatures was least; this almost coincides with the period when the maximum amount of grazing is available (June to October). In the author's view, this is decisive, and he suggests that either the nutritional value of the roughage available in the dry season has been overestimated or the amount of walking necessary to find grazing has been underestimated, and that much more supplementary feed during the dry season is required.—W. M. Deans.

3342

OLENOV, YU. M. O prichinakh razlichnoi zhirnosti posledovatel'no vydovaemykh portzii moloka. [**Causes of variation in the fat content of milk from successive strippings.**] *Dokl. Akad. Nauk S.S.S.R.*, 1954, **97**, 361-364. [Inst. Biol., Karelo-Finnish Filial Acad. Sci., U.S.S.R.]

A functional difference in the minutest lobes of the udder is postulated to account for differences in fat content of milk at different stages of milking. The fat content of the so-called residual milk, *i.e.*,

the milk after the last stripping, was greatest when the quantity of this milk was comparatively small.

Fresh cow's milk was found to contain 0.1 μ g. acetylcholine per ml., and dried whole milk 1 μ g. per g. Its possible effects on digestion in calves are discussed.—W. M. Deans.

3344

SPISNI, D. Ricerche sul contenuto di metionina e triptofano nelle proteine del latte di vacca e di pecora. [**Methionine and tryptophan content of the proteins in the milk of the cow and ewe.**] *Bol. Soc. ital. Biol. sper.*, 1954, **30**, 661-662. [Ist. Zootec. Gen., Univ. Pisa.]

In the milk of the cow and ewe, respectively, the percentage of methionine in the casein was 5.2 and 2.5, and of tryptophan 3.0 and 2.3; in the lactalbumin and globulin the percentage of methionine was 0.7 and 1.0, and of tryptophan 1.34 and 1.84.—E. M. Hume.

3345

ARCHIBALD, J. G. Aluminum in cow's milk. *J. Dairy Sci.*, 1955, **38**, 159-162. [Massachusetts Agric. Exp. Stat., Amherst.]

Al was estimated photometrically in milk from 3 pairs of cows, Ayrshire, Holstein and Jersey, matched for stage of lactation, in a cross-over experiment in which one of each pair had a supplement of Al $K(SO_4)_2 \cdot 12H_2O$, about 2 g. daily, equivalent to 114 mg. elemental Al. The milk contained on the average 0.46 mg. Al per litre, range 0.15 to 0.97, without the supplement and 0.81, range 0.39 to 1.42, with it, a difference significant at the 5 per cent. level.—W. M. Deans.

3346

SIRRY, I. and HASSAN, H. A. Composition of goat milk in Egypt. *Indian J. Dairy Sci.*, 1954, **7**, 188-193. [Fac. Agric., Univ. Cairo.]

The average percentage values for milk from 22 goats were fat 4.08, solids-not-fat 8.56, total N 0.533, casein N 0.429, albumin, globulin and proteose N 0.070, N.P.N. 0.035; sp. gr. was 1.0316 and casein number 80-52. Corresponding values for bulk milk from a flock of 6 to 14 goats were 3.97, 8.27, 0.517, 0.414, 0.070, 0.033; 1.0310 and 80.01. Sp. gr. and solids-not-fat were significantly lower than in cow's milk (100 individual samples), but the casein number was significantly higher.

ODINTZOVA, A. N. Fiziko-khimicheskie svoistva zhira koby'ego moloka. [**The physico-chemical composition of the fat of mare's milk.**] *Konevodstvo*, 1954, **24**, No. 10, 33-36. [Physico-Chem. Lab., Moscow Reg. Tuberculosis Sanatorium "Mizyri".]

The physical properties measured were the melting- and solidification-points and the refractive index. The melting-point of mare's milk fat varies between +21° and +23°, the solidification-point between -10° and -15.5° C., the refractive index between 1.4585 and 1.4606 at 40° C.

The chemical constants estimated were the amount of volatile fatty acids soluble in water, expressed by a number between 5.8 and 4.5; the saponification number, which was between 210 and 212; and the iodine number, which ranged from 80.34 to 108.

Compared with cow's milk fat the melting- and solidification-points of mare's milk fat were closer, those for cow's milk fat being from +26° to +34° and -18° to -23° C., respectively. [The refractive index for cow's milk fat was not given.] The refraction number at 40° C. was 48.5 to 51.5 for mare's milk and 42 to 45 for cow's milk fat.

The chemical properties of cow's milk fat were as follows: volatile fatty acids soluble in water 25 to 30, saponification number 222 to 232, amount of unsaturated fatty acids 25 to 40.

The fat of mare's milk was more liquid than that of cow's milk and contained more unsaturated acids. According to the amount of fatty acids soluble in water it was nearer human than cow's milk.—H. Scherbatoff.

3348

PERRIN, D. R. The chemical composition of the colostrum and milk of the sow. *J. Dairy Res.*, 1955, **22**, 103-107. [Ruakura Animal Res. Stat., N.Z. Dept. Agric.]

The initial colostrum from 4 sows had high protein and low lactose and fat contents. As in other species, protein and total solids decreased rapidly and lactose increased after parturition. The transition to milk occurred after 4 to 7 days. In contrast to other species, the ash content of the colostrum of 2 sows was lower than that of the milk, and total ash and its main constituents Ca and P increased as lactation was established.

3349

ROSS, V. and MOORE, D. H. Some properties of the casein of mouse milk (RIII). *Biochim. biophys. Acta*, 1955, **16**, 293-294. [Dept. Biochem., Coll. Phys. Surg., Columbia Univ., New York.]

A protein considered to be casein was isolated from milk of mice of the R¹¹¹ mammary-tumour-carrying strain in the concentration of approximately 2.8 per cent.—A. Hepburn.

3350

LUCKEY, T. D., MENDE, T. J. and PLEASANTS, J. The physical and chemical characterization of rat's milk. *J. Nutrition*, 1954, **54**, 345-359. [Lobund Inst. Res. Life Sci., Univ. Notre Dame, Ind.]

More than 200 lactating rats, most of them of the Wistar strain, were milked by hand under anaesthesia, each animal being milked once only, and the physical and chemical properties of the milk and colostrum were studied. On a wet weight basis colostrum contained 22 per cent. fat; milk showed considerable variations in fat content, mean 9.3 per cent.; the fat contained no butyric or caproic acid. Both milk and colostrum had a protein content of 8.7 per cent.; the protein was similar in composition to that of other milks. The milk contained 1.4 per cent. ash; this was about 3 times the ash content of colostrum. The carbohydrate content of the milk was the least variable of all the principal constituents, mean 3.7 per cent. on a wet basis. No carotene or vitamin A was found; other vitamins were present in amounts similar to those in cow's milk.

G. F. Garton.

3351

GREGORY, M. E., KON, S. K., ROWLAND, S. J. and THOMPSON, S. Y. The composition of the milk of the blue whale. *J. Dairy Res.*, 1955, **22**, 108-112. [Nat. Inst. Res. Dairying, Univ. Reading.]

Milk from 3 whales was extremely rich in fat and rich also in protein and solids-not-fat. One of the samples apparently was abnormal, as it contained only about one-twelfth as much fat as the other 2. Lactose was low and total minerals, especially Ca and P, were high. Vitamin A was lower, vitamin B₁, nicotinic acid, pantothenic acid and vitamin B₆ higher, and biotin and riboflavin about the same as in cow's milk. A strict comparison with other species is not possible because the stage of lactation was unknown.—A. Hepburn.

3352

CERUTTI, G. Sulle costanti chimico-fisiche del burro danese. [Physico-chemical constants of Danish butter.] *Ann. Sper. agrar.*, 1953, **7**, 189-192. [Inst. Indust. Agrar., Milan.] English summary.

Meat (All Kinds)

3357

WIERBICKI, E., CAHILL, V. R., KUNKLE, L. E., KLOSTERMAN, E. W. and DEATHERAGE, F. E. Meat quality. Effect of castration on biochemistry and quality of beef. *J. Agric. Food Chem.*, 1955, **3**, 244-249. [Ohio State Univ., Columbus.]

In 3 years' trials bullocks and bulls were compared. In the last trial bulls implanted once or twice at 3-month intervals in the ear with diethylstilboestrol were included. The same high standard of feeding and management applied to all

animals. Bulls fattened much more quickly and efficiently than bullocks, particularly those given 2 implantations. They had a higher percentage of edible meat, owing to less waste fat, but had lower carcass grades, and the meat was not so tender. In the treated bulls carcass grades and tenderness were very near those of bullocks. Bulls could be marketed younger than bullocks, since they reached a suitable weight sooner. Results indicated that age was the most important condition affecting tenderness, so that marketing at a standard weight would offset the tendency to toughness of bulls compared with bullocks of the same age.

In considering tenderness, biochemical studies of intramuscular fat, colour (cyanometmyoglobin) and connective tissue (hydroxyproline) showed that these were not directly related to tenderness. In all the young well-nourished carcasses studied there was little connective tissue. A consistent relation was found between tenderness and extractable N of muscle plasma. Marbling and colour give an indication of tenderness only in that they may be a guide to the age and sex of the animal.

3358

MAREČEK, V. and NĚMEČEK, J. Složení masových štáv a výluhů. [The composition of meat gravies and extracts.] *Průmysl potravin*, 1954, 5, 58-61.

The passage of nitrogenous substances from beef into the water phase at normal temperatures, 70° C. and at boiling was studied. The meat gravy or extracts were found to contain up to 20 per cent. of the total N in the form of free amino-acids. The amino-acids passed into solution in the same sequence as in hydrolysis of protein by acid and not as in digestion by pancreatic enzymes.

M. Prokšová (Czechoslovakia).

3359

GUNSTONE, F. D. Animal fats. 5. The component acids of chimpanzee fat. 6. The component acids of tiger fat and of puma fat. *Biochem. J.*, 1955, 59, 454-455; 455-458. [Dept. Chem., Univ. Glasgow.]

For previous parts see Absts. 221, Vol. 24; 273, Vol. 25.

5. By the ester-fractionation technique, chimpanzee fat was shown to contain 45 per cent. of oleic acid and 30 per cent. of palmitic acid as major components, together with octadecadienoic 8, stearic 7 and hexadecenoic acid 5 per cent. as the most important minor components.

6. Depot fats were obtained from a tiger (*Felis tigris*) and puma (*Felis concolor*), both of which had died in captivity. Ester-fractionation analysis showed that the fats were similar in composition, containing from 38 to 40 per cent. of oleic acid,

24 to 27 per cent. of palmitic acid and from 10 to 11 per cent. of stearic acid as major components; the minor component acids included octadecadienoic 6 to 9, octadecatrienoic 4 to 7, hexadecenoic 5 to 6 and myristic acid 3 to 4 per cent., with 2 to 3 per cent. of acids higher than C₁₈.

These specimens of fat contained more unsaturated acids than other analysis of tiger and puma fats reported in the literature; the difference is considered probably to be due to diet.

G. A. Garton.

3360

PATHAK, S. P. and PANDE, G. D. The component acids and glycerides of Indian crocodile (*Gavialis gangeticus*) fat. *J. Sci. Food Agric.*, 1955, 6, 48-53. [Coll. Technol., Banaras Hindu Univ., Banaras 5.]

The fatty acid and glyceride composition of the depot fat of a crocodile caught in the Ganges was studied. The saturated acids comprised palmitic 25.8, stearic 8.7, myristic 4.2 and lauric 0.2 per cent. and the unsaturated acids comprised C₁₄ 2.0, C₁₆ 11.6, C₁₈ 35.5, C₂₀ 10.0 and C₂₂ 2.0 per cent. The neutral fat contained fully saturated glycerides 7.5, mono-unsaturated-disaturated glycerides 27.7 and di-unsaturated-monosaturated glycerides 64.8 per cent.—G. A. Garton.

Fish

3361

JONES, N. R. The free amino-acids of fish. 1. Taurine in the skeletal muscle of codling (*Gadus callarias*). *J. Sci. Food Agric.*, 1955, 6, 3-9. [D.S.I.R., Torry Res. Stat., Aberdeen.]

Taurine was isolated from cod muscle in crystalline form by extraction with boiling water or hot ethanol followed by ion-exchange chromatography. It could be identified by 2-dimensional paper chromatography, and spot elution showed that the quantity was relatively constant within a batch of fresh codlings but varied considerably between batches. During storage in ice the gutted codling lost taurine continuously, most in the first 5 days. This was apparently due to seepage or "drip" on gutting and leaching by the ice-melt water. When muscle was macerated into ice-cold distilled water and marine spoilage micro-organisms were introduced no loss of taurine occurred.—A. Hepburn.

SHEWAN, J. M. The nitrogenous extractives from fresh fish muscle. 3. Comparison of several flat fishes and members of the herring-mackerel group. *J. Sci. Food Agric.*, 1955, 6, 99-104. [D.S.I.R., Torry Res. Stat., Aberdeen.]

Aqueous alcohol extracts of muscle from 6 flat fishes, lemon sole, plaice, turbot, dab, megrim and brill, and 4 pelagic fishes, herring, mackerel, Twaite shad (*Clupea finta*) and Ray's bream (*Brama raii*) were analysed as described for gadoid and elasmobranch fish (Absts. 194, Vol. 23; 2870, Vol. 24). The result for the flat fishes was similar to that found for the gadoids, the main difference being the comparatively small amounts of anserine and trimethylamine oxide and the absence of methylhistidine. Pelagic fishes were quite different from this and from one another. The salient features as compared with the gadoids were the predominance of histidine and lysine, smaller amounts of trimethylamine oxide and an apparent absence of carnosine, anserine, β -alanine and methylhistidine. Bream resembled both groups in having moderate amounts of alanine, trimethylamine oxide, anserine, some β -alanine and methylhistidine, and large amounts of histidine. Mackerel allowed to spoil in ice for 8 days contained large amounts of histamine, probably from bacterial decarboxylation of free histidine. The possible relation of this effect to food poisoning is discussed.—A. Hepburn.

MASTER, F. and MAGAR, N. G. Studies in the nutritive value of Bombay fish. 2. Amino-acid composition. *Indian J. Med. Res.*, 1954, 42, 509-513. [Dept. Biochem., Inst. Sci., Bombay.]

For Part 1 see Abst. 4391, Vol. 24.

Amino-acids were estimated microbiologically in the muscle from 6 different common edible fishes, lobster and prawn. Lysine was apparently absent from 3 of the fishes but was found in quite large amounts, ranging from 16.5 to 19.8 g. per 100 g. protein, in the other 5 species. Both tyrosine and histidine were low, on the average 1.3 and 1.6 g. The amino-acid composition compared favourably with that of casein, egg and ox muscle. A. Hepburn.

BAKKEN, K. Undersøkelser av "helmet". [Analysis of "whole meal".] *Fiskeridirektoratets Skr. Ser. Teknol. Undersøk.*, 1952, 2, No. 6, pp. 7. English summary.

"Whole meal" is fishmeal produced without loss of water-soluble protein such as occurred with older methods. In an attempt to find a criterion to distinguish between whole meal and ordinary meal, water-soluble protein, riboflavin and breakdown products of protein, by formol titration corrected for NH_3 , were estimated in 5 samples of whole herring meal and 5 of ordinary herring meal. Tests are reported also on the effect of pH on the extraction of protein, and data are given for soluble

and total protein in a series of herring meals from 1946 to 1950.

In whole meal, amine N was about 300 mg. per 100 g., and in ordinary meal about 150 mg. Total soluble protein ranged from 17 to 24 g. per 100 g. protein in whole meal, and from 6 to 7 g. in ordinary meal. Whole meal had also twice as much riboflavin as ordinary meal, 10 to 12 as against 5 to 6 μg . per g. meal.—I. Leitch.

3365

PATHAK, S. P. and PANDE, G. D. Component fatty acids of Indian shark liver oil. *J. Amer. Oil Chem. Soc.*, 1955, 32, 7-9. [Dept. Indust. Chem., Banaras Hindu Univ., Banaras 5.]

The liver oil from a species of shark (*Carcharias melanopterus*) caught in the Arabian Sea was analysed by ester-fractionation. Saturated fatty acids comprised 33.7 per cent. of the total acids, made up of palmitic acid 18.5, stearic acid 9.0, myristic acid 4.4 and arachidic acid 1.8 per cent. The unsaturated acid content was C_{14} 2.8, C_{16} 12.8, C_{18} 19.9, C_{20} 19.0, C_{22} 7.3 and C_{24} 4.3 per cent. of the total acids. The abnormally high saturated fatty acid content is discussed in relation to the composition of other elasmobranch liver oils of Indian origin.—G. A. Garton.

MALYUGA, D. P. and MAKAROVA, A. I. O soderzhanii kobal'ta v pochvakh i rasteniyakh Tuvy. [The cobalt content of soils and plants from Tuva.] *Dokl. Akad. Nauk S.S.S.R.*, 1954, 98, 811-813. [V.I. Vernadsky Inst. Geochem., Acad. Sci., U.S.S.R.]

The average cobalt content, from analyses of hundreds of soil samples from different parts of the region, of mountain-chestnut, mountain-forest dark grey, mountain chernozem and other soils was 1.5×10^{-3} per cent. There was a definite relation between the amounts of Co in soils

animals. Bulls fattened much more quickly and efficiently than bullocks, particularly those given 2 implantations. They had a higher percentage of edible meat, owing to less waste fat, but had lower carcass grades, and the meat was not so tender. In the treated bulls carcass grades and tenderness were very near those of bullocks. Bulls could be marketed younger than bullocks, since they reached a suitable weight sooner. Results indicated that age was the most important condition affecting tenderness, so that marketing at a standard weight would offset the tendency to toughness of bulls compared with bullocks of the same age.

In considering tenderness, biochemical studies of intramuscular fat, colour (cyanometryoglobin) and connective tissue (hydroxyproline) showed that these were not directly related to tenderness. In all the young well-nourished carcasses studied there was little connective tissue. A consistent relation was found between tenderness and extractable N of muscle plasma. Marbling and colour give an indication of tenderness only in that they may be a guide to the age and sex of the animal.

T. D. Bell.

3358

MAREČEK, V. and NĚMEČEK, J. Složení masových štáv a výluhů. [The composition of meat gravies and extracts.] *Průmysl potravin*, 1954, 5, 58-61.

The passage of nitrogenous substances from beef into the water phase at normal temperatures, 70° C. and at boiling was studied. The meat gravy or extracts were found to contain up to 20 per cent. of the total N in the form of free amino-acids. The amino-acids passed into solution in the same sequence as in hydrolysis of protein by acid and not as in digestion by pancreatic enzymes.

M. Prokšová (Czechoslovakia).

GUNSTONE, F. D. **Animal fats.** 5. The component acids of chimpanzee fat. 6. The component acids of tiger fat and of puma fat. *Biochem. J.*, 1955, 59, 454-455; 455-458. [Dept. Chem., Univ. Glasgow.]

For previous parts see Absts. 221, Vol. 24; 273, Vol. 25.

5. By the ester-fractionation technique, chimpanzee fat was shown to contain 45 per cent. of oleic acid and 30 per cent. of palmitic acid as major components, together with octadecadienoic 8, stearic 7 and hexadecenoic acid 5 per cent. as the most important minor components.

6. Depot fats were obtained from a tiger (*Felis tigris*) and puma (*Felis concolor*), both of which had died in captivity. Ester-fractionation analysis showed that the fats were similar in composition, containing from 38 to 40 per cent. of oleic acid,

24 to 27 per cent. of palmitic acid and from 10 to 11 per cent. of stearic acid as major components; the minor component acids included octadecadienoic 6 to 9, octadecatrienoic 4 to 7, hexadecenoic 5 to 6 and myristic acid 3 to 4 per cent., with 2 to 3 per cent. of acids higher than C₁₈.

These specimens of fat contained more unsaturated acids than other analysis of tiger and puma fats reported in the literature; the difference is considered probably to be due to diet.

G. A. Garton.

PATHAK, S. P. and PANDE, G. D. **The component acids and glycerides of Indian crocodile (*Gavialis gangeticus*) fat.** *J. Sci. Food Agric.*, 1955, 6, 48-53. [Coll. Technol., Banaras Hindu Univ., Banaras 5.]

The fatty acid and glyceride composition of the depot fat of a crocodile caught in the Ganges was studied. The saturated acids comprised palmitic 25.8, stearic 8.7, myristic 4.2 and lauric 0.2 per cent. and the unsaturated acids comprised C₁₄ 2.0, C₁₆ 11.6, C₁₈ 35.5, C₂₀ 10.0 and C₂₂ 2.0 per cent. The neutral fat contained fully saturated glycerides 7.5, mono-unsaturated-disaturated glycerides 27.7 and di-unsaturated-monosaturated glycerides 64.8 per cent.—G. A. Garton.

JONES, N. R. **The free amino-acids of fish. 1. Taurine in the skeletal muscle of codling (*Gadus callarias*).** *J. Sci. Food Agric.*, 1955, 6, 3-9. [D.S.I.R., Torry Res. Stat., Aberdeen.]

Taurine was isolated from cod muscle in crystalline form by extraction with boiling water or hot ethanol followed by ion-exchange chromatography. It could be identified by 2-dimensional paper chromatography, and spot elution showed that the quantity was relatively constant within a batch of fresh codlings but varied considerably between batches. During storage in ice the gutted codling lost taurine continuously, most in the first 5 days. This was apparently due to seepage or "drip" on gutting and leaching by the ice-melt water. When muscle was macerated into ice-cold distilled water and marine spoilage micro-organisms were introduced no loss of taurine occurred.—A. Hepburn.

DESIKACHAR, H. S. R. Determination of the degree of polishing in rice. 1. Some methods for comparison of the degree of milling. 2. Determination of thiamine and phosphorus for processing control. 3. The use of colored rice as an indicator of the degree of bran removal in rice milling. *Cereal Chem.*, 1955, 32, 71-77; 78-80; 80-82. [Div. Food Processing, Central Food Technol. Res. Inst., Mysore.]

1. Samples of 3 varieties of rice polished to 12 different degrees were used in the preliminary study of possible rapid, simple methods of assessing degree of polishing. Several such tests are described, some of use only for comparative purposes. Figures showing the loss of vitamin B₁ on milling are included.

2. A rapid (30-min.) method for estimating vitamin B₁ consists in shaking 5 g. rice flour with 50 ml. of 10 N H₂SO₄ for 10 min., adjusting to pH 4 with Na acetate, making up to 100 ml., filtering and estimating vitamin B₁ by the thiochrome method. Results for 6 differently milled

samples of one variety were about 10 per cent. lower than those by the complete extraction method of Kik and Williams (Abst. 4134, Vol. 16).

A rapid method for estimating P consists in digesting 0.5 g. rice flour with 2 ml. concentrated H₂SO₄ for 5 min., making up to 100 ml., filtering and using 5- to 10-ml. aliquots for estimation of P by the method of Fiske and Subbarow. Results were from 92 to 95 per cent. of these obtained by the complete digestion method of Gerritz (Abst. 44, Vol. 5).

Both methods are considered suitable for control of rice processing.

3. Vitamin B₁ was estimated by the method of Kik and Williams in 6 differently milled samples of a natural mixture of white rice and 7 to 8 per cent. of red rice and in the white and red rices separately; and when the bran pigments of the red rice were extracted with hot NaHCO₃ solution, its colour was found to serve as a measure of the degree of milling, very sensitive in the early stages of milling. Since both types of rice lost vitamin B₁ at the same rate, the use of red rice as an indicator is suggested. Rice polished to remove 85 per cent. of the bran contained about 2 µg. vitamin B₁ per g., sufficient to prevent beriberi on a rice diet.—W. M. Deans.

3371

PARIHAR, D. B. Saccharides of different varieties of Indian rice. *Nature*, 1955, 175, 42-43. [Defence Sci. Lab., Hillside Rd., New Delhi.]

Saccharides were estimated by circular paper chromatography in 4 samples of raw rice, one 3 years old, two 1 year old and one new, and in 3 varieties of parboiled rice, two 1 year old and one 3 years old. New raw rice contained only fructose, glucose and suerose. All other samples contained in addition galactose, maltose, raffinose and maltotriose. Isomaltose and maltotetraose were found only in the 3-year-old samples. Raffinose was more abundant in the parboiled rice. The changes in older samples, possibly due mostly to the action of α -amylase on starch, may improve digestibility and taste.—A. Hepburn.

SCHWIMMER, S., BEVENUE, A., WESTON, W. J. and POTTER, A. L. Survey of major and minor sugar and starch components of the white potato. *J. Agric. Food Chem.*, 1954, 2, 1284-1290. [W. Utilization Res. Branch, Agric. Res. Serv., U.S. Dept. Agric., Albany 6, Calif.]

The alcohol-soluble sugars of potatoes were analysed quantitatively and by paper chromatography after storage at 40°, 50° or 70° F. The

N.A. and B., July 1955

main sugars found were glucose, fructose and sucrose. Fresh potatoes contained very little sugar, most of it at 40° F. with a maximum after about 4 weeks. Lowering the storage temperature to 34° F. after 18 weeks increased the total sugar, especially reducing sugar, but raising the temperature to 70° F. produced considerable decreases. During low-temperature storage sucrose initially rose more rapidly than the reducing sugars, but the position was soon reversed. In 4 varieties of potato studied the glucose:fructose ratio approached unity at low temperatures and was consistently above 2 at higher temperatures. The variety White Rose, which had a superior capacity for accumulating total sugar, had corresponding ratios of about 0.5 and unity.

Paper chromatography showed the presence of heptulose in all samples, and some contained substances tentatively identified as melibiose, melezitose, raffinose and a non-moving fructosan. Storage time and temperature did not alter the amylose-amylopectin ratio or the phosphorus content of the starches isolated from the potatoes. A. Hepburn.

3373

SCHWIMMER, S., BEVENUE, A. and WESTON, W. J. **Phosphorus components of the white potato.** *J. Agric. Food Chem.*, 1955, **3**, 257-260. [W. Utilization Res. Branch, Agric. Res. Serv., U.S. Dept. Agric., Albany 6, Calif.]

The acid-soluble phosphate of 2 varieties of potatoes was studied by fractionation of the barium salts of the phosphate esters and paper chromatography.

From one-half to two-thirds of the total phosphorus was acid-soluble. During storage for up to 21 weeks the Ba-soluble fractions increased at first, but decreased later. Chromatographic spots were tentatively ascribed to orthophosphate, glycerol phosphate, phosphoglyceric acid, fructose diphosphates, nucleotide and phytate. There was evidence of 5 other unknown phosphates. It is suggested that orthophosphate, and not the hexose phosphates, may play a part in the non-enzymic browning of processed potatoes. In these 2 varieties the ratio of P content of starch to total P in tuber was the same, and it is suggested that the starch serves as a metabolic storage reservoir for P.—W. M. Deans.

Leafy Vegetables

3374

PARRÁKOVÁ (Ed.). **Stanovenie jódu v jodozovanej zelenine. [Iodine estimation in the iodised vegetable.]** *Biológia*, 1954, **9**, 347-358. [Inst. Plant Physiol., Slovak Univ., Bratislava.] German and Russian summaries.

The I content of iodised salad and spinach was estimated. Small quantities of I in aqueous

solution as KI stimulated germination and growth of plants. The I content of plants could be increased only by gradually increasing the I content of the soil, not by larger doses of I. The possibility of iodised plants serving as a prophylactic for children in regions with endemic goitre is considered.—A. Jančářík (Czechoslovakia).

PESOLA, V. A. **Protein content of field pea seeds as a varietal character.** *Acta agr. fenn.*, 1955, **83**, 125-132. [Dept. Plant Breeding, Agric. Res. Centre, Jokioinen, Finland.]

Crude protein as a percentage of dry matter is given for some 30 varieties or strains of field pea grown under standard conditions in 6 seasons at the Agricultural Research Centre, Jokioinen. The Svalöf variety of Torsdags II had a mean protein content of 20.42 per cent., but a number of varieties being developed at the Centre or from elsewhere surpassed this, one having almost 23 per cent. Apart from low values in one dry summer, it was concluded that differences in protein content of peas are mainly genetic. Protein content could not be related to size, weight or colour of pea.

3376

YAMAGUCHI, M., MACGILLIVRAY, J. H., HOWARD, F. D., SIMONE, M. and STERLING, C. **Nutrient composition of fresh and frozen lima beans in relation to variety and maturity.** *Food Res.*, 1954, **19**, 617-626. [Dept. Veg. Crops., Univ. California, Davis.]

The 2 main types of bean studied, baby Lima and Fordhook, were divided into 3 grades of maturity. They were analysed fresh and after blanching and freezing. The locality where they were grown made no apparent difference. Baby Lima beans had a higher mineral content and a higher nutrient value but a lower organoleptic score (on the cooked frozen samples) than the Fordhook beans. In both types of bean total solids, alcohol-insoluble solids, starch, protein and minerals increased with maturity, ascorbic acid and carotene decreased and vitamin B₁, riboflavin and nicotinic acid changed only slightly. Ascorbic acid, carotene and the B vitamins decreased after blanching and freezing.—A. Hepburn.

- MOURA CAMPOS, F. A., DE SIQUEIRA, R. and PECHNIK, E. Contribuição ao estudo do valor nutritivo de alguns óleos e de algumas castanhas nacionais. [Contribution to the study of the nutritive value of some indigenous oils and "chestnuts"]. *Biblioteca Brasil. de Nutrição* 9, *Serv. Aliment. da Previdência Social*, 1953, pp. 160.

In this monograph on the nutritive value of Brazilian oils a description is given of 60 plants or trees from which oil is obtained. The data, collected from many sources, include in most cases the yield of oil, many of the physical constants, and in some cases information on the vitamin content. For 21 of the plants supplementary information is given based on personal experimental work of the authors, dealing with such subjects as energy value, vitamin A content of the oil, its chemical composition and digestibility, content of saturated and non-saturated fatty acids, retention of carotene by the oil under different conditions of light and temperature, and biological experiments. This is followed by a comparative study of the principal oils, classified according to the oil content of the whole fruit, mesocarp, seeds and bran. Estimations are given of oleic, linoleic and ricinoleic acids in 7 of the plants.

In some regions of Brazil oils of animal origin are used in cooking. Seven fish oils are described, with data on vitamin content, energy value and physical constants, based in some cases on work by the authors. A brief chapter summing up the energy value of the oils includes results of the authors for 9 oils, in which the energy value ranges from 886.8 to 939.2 Cal. per 100 g.

The second part of the monograph deals with the nutritive value of native nuts. These are in general rich in lipids and proteins, the latter being of good quality, with a high biological value and good digestibility. Comparative tables of data from different sources show that the proteins

of the cashew nut and soya bean approximate most closely to proteins of animal origin. A detailed study is given of 6 nuts which are of great nutritional importance in Brazil: groundnut, Brazil and cashew nuts, the "Sapucaia" nut (*Lecythis usitata*), and the nuts of the Brazilian rubber tree "Seringueira" and of *Aracaria angustifolia*. The studies include data on chemical composition from different sources, including personal results, with a description in some cases of biological experiments illustrating the value of the oils as a source of protein or vitamins. The methods used by the authors are given in an appendix.

- NARAYANA RAO, M. and KRISHNA MURTHY, K. Gossypol content of Indian cottonseed and cottonseed oil. *Bull. Central Food Technol. Res. Inst. Mysore*, 1954, 3, 311. [Div. Biochem. Nutrit.]

The free gossypol content of the whole seed, kernel, oil and refined oil of 9 varieties of Indian cottonseed was estimated and the value for whole seed was found to range between 0.70 and 0.92 per cent. compared with 1.9 to 3.0 per cent. for Egyptian and Sea Island varieties of cottonseed. When oil obtained by hydraulic pressing was refined it contained no gossypol.—D. H. Shrimpton.

- HOLMES, W. and MACLUSKY, D. S. The intensive production of herbage for crop-drying. 5. The effect of continued massive applications of nitrogen with and without phosphate and potash on the yield of grassland herbage. *J. Agric. Sci.*, 1954, 45, 129-140. [Hannah Dairy Res. Inst., Kirkhill, Ayr.]

Herbage yields and composition obtained during the fourth, fifth and sixth years of a small scale

N.A. and R., July 1955

plot experiment are reported (for report on the first 3 years see Absts. 274, 3252, Vol. 19; 3271, Vol. 21). Fertiliser treatments applied each year were 0, 260, 520 or 416 lb. N, with no P or K, 336 to 538 lb. K_2O , 120 to 180 lb. P_2O_5 or both these quantities of P and K at all levels of N, applied in 4 or 5 dressings, one after each herbage cutting. With potash present there was a high, maintained, response to N, the average dry matter and crude protein yields over the whole 6 years at all 4 levels of N application being 7940 and 1410 lb. per acre, respectively. Corresponding yields in the absence of K were 4970 and 960 lb. per acre, respectively. The effect of P was negligible. The botanical composition depended on N and K; the presence of both maintained a vigorous ryegrass-timothy sward. K alone gave a clovery sward, but in its absence, with or without N, there was an invasion of the poorer grasses, which depressed early-season production.—J. L. Corbett.

3384

PELTON, W. L. and WEBBER, L. R. The effects of irrigation and chemical fertilization on the yield and protein content of a pasture mixture. *Canad. J. Agric. Sci.*, 1955, **35**, 1-10. [Dept. Soils, Ontario Agric. Coll., Guelph.]

Small-scale plots of grass with clover were irrigated to maintain 4 different soil-moisture contents. With increasing applications of water, production of dry matter and crude protein was raised significantly and the proportion of clover in the herbage increased. Heavy application of fertilisers also significantly increased total dry matter and crude protein production and the protein content of the grass at each level of watering, but proportionately decreased clover yields.—J. L. Corbett.

3385

CUNNINGHAM, I. J. and HOGAN, K. G. Oestrogens in New Zealand pasture plants. *N.Z. Vet. J.*, 1954, **2**, 128-134. [Wallaceville Animal Res. Stat., Dept. Agric., Wellington.]

Oestrogens in pasture plants in all seasons from representative areas of New Zealand were estimated by the mouse uterus method. There was a high content of oestrogen in subterranean clover at all seasons and from all districts, and there was a slight trace in some samples of white clover. When pure species of grasses and clover were examined, appreciable amounts of oestrogen were found in subterranean and red clover at all seasons. In early spring there were small amounts in short-rotation and perennial ryegrasses.

An instance of lactation occurring in wethers is reported. The cause seemed to be the presence of subterranean and red clovers in the pastures which they had grazed.—T. D. Bell.

CAMPANILE, S. Su la composizione chimica del *Trifolium thalii* Vill. [Chemical composition of *Trifolium thalii*, Vill.] *Ann. Sper. agrar.*, 1954, **8**, 741-745. [Staz. Chim.-Agrar. Sper., Rome.] English summary.

Trifolium thalii, Vill. grows in dry mountain pastures, forming a valuable fodder with little fibre. Chemical analysis gave the following percentage composition: moisture 16.6, crude protein 22.75, ether extract 2.4, crude fibre 11.3, ash 7.25 and N-free extract 39.7.—T. D. Bell.

3388

DOUGALL, H. W. The composition of green oats for forage and ensilage. *East African Agric. J.*, 1954, **20**, 118-119. [Dept. Agric., Kenya.]

Green oats after initial grazing by cattle and again 7 weeks later after several days' grazing contained on the average crude protein 32.17, true protein 25.85, carbohydrate (by difference) 32.90, and crude fibre 19.26 per cent. The percentage digestibility of the crude protein was 86.15, the protein equivalent 24 and the starch equivalent 70. As the crop matured protein, oil and minerals decreased, carbohydrate and crude fibre increased and the protein became less digestible. At the full flowering stage the composition was crude protein 8.13, true protein 4.71, carbohydrate 56.01, crude fibre 28.05 per cent. and the percentage of digestibility of the crude protein was 46.74. Although its composition was poorer the maturer crop was considered more economical for silage making because of the greater yield. A companion crop, the legume Serradella, at the time of harvesting was rich in highly digestible protein, was not fibrous and could produce better mixed silage.—A. Hepburn.

JANSEN, B. C. P. **Vitamines on anti-vitamins. [Vitamins and antivitamins.]** *Voeding*, 1954, **15**, 520-526.

This short review is intended to form part of a textbook of modern nutrition (see Abst. 3588, Vol. 24).—I. Leitch.

3392

WOERNLEY, D. L. **The magnetochemistry of vitamins.** *Arch. Biochem. Biophys.*, 1955, **54**, 378-383. [Dept. Biophys., Roswell Park Mem. Inst., Buffalo, N.Y.]

The magnetic susceptibility of a number of vitamins was measured by the Gouy method as previously described (*J. Biol. Chem.*, 1954, **207**, 717). The experimental results for ascorbic acid, biotin, Ca pantothenate, folic acid, 2-methylnaphthoquinone, nicotinic acid and α -tocopherol were in close agreement with theoretical values. Values for magnetic susceptibility are useful in the characterisation of complex compounds and as a criterion of purity.—A. M. Copping.

3393

STEINER, P. E., RASMUSSEN, T. B. and FISHER, L. E. **Neuropathy, cardiopathy, hemosiderosis, and testicular atrophy in Gorilla gorilla.** *Arch. Pathol.*, 1955, **59**, 5-25. [Dept. Pathol., Univ. Chicago, Ill.]

The full post-mortem picture is described of a 22-year-old male gorilla which died after an illness lasting 7 months. There was diffuse chronic degenerative change in the spinal cord and dorsal root ganglia with secondary degeneration of ascending tracts and of peripheral nerves, combined with atrophy of muscles of the extremities and a chronic ulcer on the left foot. Other findings were changes in the heart suggestive of beriberi, slight arteriosclerosis in the brain and spinal cord, haemosiderosis and atrophy in the liver and spleen, severe tubular atrophy and fibrosis of the testes, and obesity, besides recent changes indicative of death from acute congestive heart failure.

In a discussion of the findings and of the conditions reported in other captive gorillas, it is sug-

gested that despite all efforts to provide the known nutritional requirements, there was some dietary defect. The restricted distribution of the gorilla in nature suggests the possibility that its requirements are more exacting than those of the chimpanzee. The lesions are compatible with deficiency of several vitamins of the B complex and of vitamin E.

There was no sign that the animal was senile.
D. Duncan.

3394

WAHL, O. and BACK, E. **Einfluss der im Pollen enthaltenen Vitamine auf Lebensdauer, Ausbildung der Pharynxdrüsen und Brutfähigkeit der Honigbiene (*Apis mellifica*).** [Effect of the vitamins in pollen on life span, formation of pharynx glands and hatching capacity in the honeybee (*Apis mellifica*).] *Naturwissenschaften*, 1955, **42**, 103-104. [Lehr- u. Versuchsanst. Bienenzucht, Marburg a.d. Lahn.]

In bees kept at controlled temperatures in cages there was no difference in life span on purified basal diets with or without vitamins. The pharynx glands developed moderately well without addition of vitamins but attained full size only with vitamin supplements, of which pantothenic acid appeared to be specially active. Hatching and larval development were improved by inclusion of protein and vitamins in the diet.—A. M. Copping.

3395

DIAMANT, E. J., HALEVY, S. and GUGGENHEIM, K. **Studies on vitamin metabolism in emetine poisoning.** *J. Nutrition*, 1955, **55**, 241-253. [Lab. Nutrit., Dept. Biochem., Hebrew Univ.-Hadassah Med. Sch., Jerusalem, Israel.]

The effect of repeated small daily doses of 0.05 mg. emetine hydrochloride was studied in young rats for 4 weeks. Rats given emetine lost appetite and gained only 28 ± 2.4 g. during the experiment. Pair-fed rats without emetine gained 55 ± 2.0 g. and those with unrestricted food intake 70 g. No change was detected in metabolism of vitamin A, riboflavin, nicotinic acid, biotin, or pantothenic acid in the rats receiving emetine. Storage of vitamin B₆ and folic acid in the liver, excretion of folic and ascorbic acid in the urine, and the amount of citrovorum factor synthesised after injection of folic and ascorbic acid, were all less in the rats given emetine. Storage of ascorbic acid was lower in the liver and higher in the adrenal glands than for normal rats, but the synthesis of ascorbic acid in response to barbiturate was not impaired.—A. M. Copping.

3396

RICKELS, K. Über die Wachstumsbeeinflussung von pathogenen Keimen durch Vitamine. [Influence of vitamins on the growth of pathogenic organisms.] *Münch. med. Wochenschr.*, 1954, **96**, 1510-1511. [Pathol. Bakteriolog. Inst., Stadt Krankenhaus, Kassel.]

The possibility that vitamin C or members of the vitamin B complex might inhibit growth of pathogenic bacteria was investigated with 203 strains of cocci, *Bacterium coli* and *Bacterium proteus*. Only panthenol as Bepanthen had any inhibiting effect, which was shown with pneumococci, streptococci and staphylococci in presence of high concentrations of the vitamin. The clinical use of Bepanthen given by mouth in infections is suggested.—A. M. Copping.

3397

BERGER, M. Wirkung von Vitaminen und Hormonen auf einige Protozoen. [Effect of vitamins and hormones on certain protozoa.] *Internat. Ztschr. Vitaminforsch.*, 1955, **25**, 434-442. [Frauenklin., Univ. Bern.] English and French summaries.

It was sought to ascertain whether ciliate and flagellate protozoa could be used for a pregnancy test. They were grown from pure culture in flasks containing 1 litre of water with 10 ml. filtered juice from briefly cooked, fresh carrots. After 4 re-inoculations in about 10 weeks they were suitable for test. Test cultures contained 10 ml. of the stock culture, 80 ml. water and 5 drops carrot juice with the test substance added. The numbers of protozoa in 8 drops of culture were counted daily for a week.

All the substances tested were inhibitory or lethal in excessive doses. With *Chilomonas* sp. and *Glaucoma scintillans*, urine from pregnant subjects produced much more growth than urine or serum from non-pregnant subjects. Slightly too much serum or urine caused an initial setback followed by intensive growth. With correct concentrations the accuracy of the test was from 71 to 74 per cent. in 50 tests with pregnant, and 50

with non-pregnant urine. *Paramoecium caudatum* could not be used.

Some stimulation was produced by preparations of serum gonadotropin and chorionic gonadotropin, especially the former. Bacterial growth in the cultures increased also. The greatest stimulation was given by thymophysin, insulin, Cortrophine or a mixture of B vitamins. Vitamin C, pituitary hormones, adrenaline, thyroxine and individual vitamins of the B group had little or no effect. Small doses of oestrogens were ineffective, larger doses lethal.—D. Duncan.

3398

WODSACK, W. and UECKERMAN, E. Die Vitamin-gehalte der wichtigsten Baumrinden und deren möglicher Einfluss auf das Schälen des Rotwildes. [Vitamin contents of the more important barks of trees and their possible bearing on bark stripping by red deer.] *Internat. Ztschr. Vitaminforsch.*, 1955, **25**, 379-384. [Chem. Anst., Hyg. Inst., Hamburg.] English and French summaries.

To test the idea that red deer may strip the bark of trees in order to make up for vitamin or other deficiencies of their diet, samples of the bark of common coniferous and deciduous trees taken in October (7 species) and April (9 species) were analysed for vitamin B₁ by the thiochrome method as described by Müller and Moor (Abst. 4631, Vol. 19), riboflavin by the lumiflavin method of Roth [no reference], nicotinic acid by a modification of the method of Ritsert (Abst. 2960, Vol. 9) and vitamin C by Kuhn's version of the dichlorophenolindophenol method (Abst. 3047, Vol. 11).

Some of the amounts found were noteworthy; for instance, the vitamin C value in mg. per 100 g. fresh substance was for oak bark in spring 32, for spruce 17.1 and for alder 15.6, which also had 10 mg. nicotinic acid per 100 g., but the values bore no relation to the observed preferences of the deer.

Experiments with salt licks fortified with vitamins or trace elements have so far given negative results.—W. M. Deans.

VITAMIN A

3399

SCOTT, N. Rapid assay for vitamin A. *Chemist-Analyst*, 1954, **43**, 97. [Vitarine Co., Inc., 636 Eleventh Ave., New York.]

A modification of the U.S.P. spectrophotometric method for estimating vitamin A is described. The simplified procedure has the advantage of being more rapid and of not requiring any special glassware or large quantities of ether. A sample containing about 100 U.S.P. units of vitamin A

was weighed directly into a Maizel Gerson saponification vessel; a second vessel was used for a blank estimation. To each vessel 0.35 ml. of 50 per cent. alcoholic KOH and 5 ml. of ethanol were added. The vessels were refluxed for 15 min.; the contents were extracted with 10 ml. ether. The ether extract was washed 3 times with water and then evaporated in a stream of nitrogen. Next, 10 ml. isopropanol were pipetted into each vessel and after being thoroughly shaken the new solutions

were transferred to cuvettes and their absorption was measured at 310, 325 and 334 $m\mu$ in a spectrophotometer. The Morton Stubbs correction was applied. Results obtained with U.S.P. Reference oil and with cod liver oil and percomorph liver oil by this rapid method gave good agreement with those obtained by the standard U.S.P. method.—I. M. Sharman.

3400

CORMIER, M. De l'époxyde de vitamin A à la vitamine A alcool. [From vitamin A epoxide to vitamin A alcohol.] *Bull. Soc. Chim. biol.*, 1954, 36, 1255-1264.

A solution of vitamin A alcohol was treated with MnO_2 in the dark by Morton's method. The progress of the oxidation was followed by recording the ultraviolet absorption spectrum with a Beckman spectrophotometer. Five min. after the addition of MnO_2 the maximum absorption changed from 325 $m\mu$ to maxima at 330 and 335 $m\mu$, indicating the presence of the hydrate of vitamin A aldehyde. After 60 min. the maximum absorption shifted to 368 $m\mu$ because of the presence of vitamin A aldehyde. A similar band was observed after 4 hr., but after 6 hr. maximum absorption was at 347 $m\mu$, possibly because of the presence of vitamin A acid. In another series of experiments when the production of vitamin A aldehyde was considered to be at its maximum 3 per cent. of absolute ethanol was added to the light petroleum mixture, according to Meunier's method, and records of the absorption spectra were continued. From 1 to 18 hr. after the addition maxima at 347 and 280 $m\mu$ occurred, probably indicating the presence of vitamin A acid and an isomer of vitamin A epoxide; 48 hr. after the addition maxima were found at 335 and 280 $m\mu$, showing the presence of the hydrate of the aldehyde and the isomer or "precursor" of the epoxide of vitamin A. After 4 more days maxima were found at 335 and 275 $m\mu$, indicating the presence of the hydrate of vitamin A aldehyde and the true epoxide of vitamin A.

In further tests the reverse reaction was studied, in which vitamin A epoxide was reduced to vitamin A alcohol in the presence of zinc oxide activated by heating to 1200°C. Absorption maxima at 280 and 365 to 368 $m\mu$ were then observed, indicating the presence of modified vitamin A epoxide and vitamin A aldehyde. Data for the optical densities are presented for all the results obtained and the significance of the substances absorbing at 335 $m\mu$ and 280 $m\mu$, respectively, is discussed.

I. M. Sharman.

3404

WALD, G. Visual pigments and vitamins A of the clawed toad, *Xenopus laevis*. *Nature*, 1955, 175, 390-391. [Biol. Labs., Harvard Univ., Cambridge, Mass.]

Dartnall (*J. Physiol.*, 1954, 125, 25) extracted from the retina of *Xenopus* a visual pigment having maximum spectral absorption at about 515 $m\mu$. He believed it to be a new pigment. The observation is confirmed. Rhodopsin and porphyropsin have maxima at 500 and 522 $m\mu$, respectively. The pigment from *Xenopus* could, therefore, be a mixture of the two. Such a mixture can be analysed by exposing it to light, when rhodopsin is bleached to vitamin A and porphyropsin to vitamin A₂. The two vitamins are readily identified by treatment with the $SbCl_5$ reagent; the products formed have spectral maxima at 620 and 690 $m\mu$, respectively. An extract from *Xenopus* eyes was so treated and the spectrum was recorded. It showed a peak near 690 $m\mu$ and a broad elevation in the region of 620 $m\mu$.

It is concluded that the principal retinal pigment from *Xenopus* is porphyropsin, accompanied by a small proportion of rhodopsin. The significance is discussed of the discovery for the first time of porphyropsin in an adult anuran.—V. H. Booth.

BLAZOT, J. and SERFATY, A. Intensité respiratoire du diaphragme isolé de rat; influence de l'avitaminose A. [Rate of respiration of the isolated rat diaphragm; effect of vitamin A deficiency.] *Arch. Sci. physiol.*, 1955, 9, 1-9. [Lab. Physiol. Gén., Fac. Sci., Toulouse.]

Weanling male albino rats were paired as equally as possible according to their weight. One animal from each pair was given a diet deficient in vitamin A. The remaining animals were given the same diet with weekly supplements of 5000 I.U. vitamin A. As each of the animals in the first group became deficient, as shown by a fall in its growth curve, portions of its diaphragm were isolated. The diaphragm from the corresponding control animal was also examined at the same time. Rates of oxygen consumption were measured by the Warburg method. The rats when examined weighed between 150 and 225 g. The isolated tissues from the deficient animals respired more actively than those from the control animals. The average weight of dry tissue examined from the deficient animals was 10.6 mg. and absorbed on the average 4.23 c. mm. oxygen per mg. per hr., corresponding values for the control animals being 11.6 mg. and 3.80 c. mm., respectively. The difference in the respiration rates varied with the weight of the isolated tissue, being 8 per cent. in favour of the deficient animals when the weight of tissue was 5 mg. and 11 per cent. when 20-mg. portions were examined.—I. M. Sharman.

O'DONOGHUE, J. G. Blindness in beef cattle and its possible relationship to vitamin A deficiency.

Vol. 25, No. 3

Canad. J. Comp. Med., 1955, 19, 61-64. [Vet. Serv. Branch, Alberta Dept. Agric.]

About 6 cases of blindness were seen in yearling beef cattle from 3 or 4 herds. Ophthalmoscopic examination of 2 of them showed degenerative changes and oedema of the optic disc. Dissection of the optic nerves of one animal showed that there was a constriction at the point of passage through the foramen, like that which has been ascribed by previous workers to deficiency of vitamin A.

T. Moore.

3410

WOOLLAM, D. H. M. and MILLEN, J. W. Effect of vitamin A deficiency on the cerebro-spinal fluid pressure of the chick. *Nature*, 1955, 175, 41-42. [Dept. Anat., Univ. Cambridge.]

In chicks maintained on a diet with 1.6 mg. carotene per kg. as sole source of vitamin A, the cerebrospinal fluid pressure was on the average at the age of 30 days 108 mm. water, at 62 days 157, at 88 days 180 and at 125 days 212. In 10 normal chicks of comparable ages the pressure remained under 100 mm. The chicks showed no sign of neurological disease while alive, and no abnormality could be found in the bones at necropsy. It is concluded that raised cerebrospinal fluid pressure is an early sign of vitamin A deficiency and that it appears before any overt sign of neurological disturbance.—T. Moore.

3411

KÖHLER, H. Die Hyperkeratose, ein Problem des Vitamin A-Stoffwechsels. [*Hyperkeratosis, a problem of vitamin A metabolism.*] *Arch. Tierernährung*, 1954, No. 5, Beihfte, 283-291. [Pathol. Inst., Tierärztl. Hochschule, Hanover.]

The hyperkeratosis induced by wood preservatives or by pure chlorinated naphthalenes was studied with several farm animals, mainly with cocks. Confirmation was obtained that the lesions resemble those seen in vitamin A deficiency and that the concentration of vitamin A in the blood is greatly reduced. Trichlorinated naphthalene was not toxic, but toxicity was present with 4 atoms of chlorine and increased with 5 or 6 atoms. The effect of the poison could usually be seen first in the epithelium of the sub-mucosal glands of the oesophagus, which became keratinised. In young cocks spermatogenesis was arrested, and in older birds the germinal epithelium degenerated and desquamated. Growth stopped, and resistance to infections fell. The lesions varied considerably in different species.—T. Moore.

3412

FERRANDO, R. Hypothèses à propos des relations pouvant exister entre la maladie X, les phénomènes de desintoxication et la vitamine A. [*Hypotheses on the relations between X disease,*

the phenomena of detoxication and vitamin A.]

Bull. Soc. Chim. biol., 1954, **36**, 1245-1247.

[École Vét., Lyons.]

It is suggested that the production of X disease (hyperkeratosis) in cattle may be caused not by a direct antagonism between chlorinated naphthalenes and vitamin A, but by the strain caused by the naphthalenes on the detoxicating mechanism of the organism, which, in turn, causes an increased demand for vitamin A, as was shown by previous work on the detoxication of bromobenzene (Abst. 1625, Vol. 20). It is considered that the value of methionine or cystine in the treatment of X disease should be investigated.—T. Moore.

Univ., Szeged.]

3414

VAN DYKE, J. H. Experimental thyroid metaplasia in the rat: preliminary report. *Arch. Pathol.*, 1955, **59**, 73-81. [Div. Anat., Hahnemann Med. Coll., Philadelphia, Pa.]

Very young Sprague Dawley rats were maintained on a vitamin-A-deficient diet for from 10 to 40 days; some were killed every 10 days for examination of the thyroid gland. After periods of depletion some were given a diet of Purina dog chow, adequate in vitamin A and fortified with carotene, together with a single initial dose of cod liver oil. Some were killed every 2 days and the thyroid glands were examined for signs of repair.

After the 20th day of vitamin A depletion there was degeneration or atrophy of the parenchyma of the gland in the centres of the lobes. When the vitamin-A-deficient rats received the adequate diet, these cysts gradually disappeared, the time required depending on the severity of the deficiency and the extent of the metaplastic lesion. Aberrant cell remnants of the lesion sometimes persisted after repair, and it is suggested that they might be a source of certain thyroid neoplasms. The paper is illustrated by photomicrographs of histological sections from thyroid cysts developing, and undergoing the process of repair.—B. W. Simpson.

3415

KAHN, R. H. Effect of locally applied vitamin A and estrogen on the rat vagina. *Amer. J. Anat.*, 1954, **95**, 309-335. [Dept. Zool., Univ. California, Berkeley.]

Female albino rats, ovariectomised when about

4 months old, were used to test the effect of α -oestradiol, alone or in conjunction with vitamin A, applied in sesame oil to the vaginal epithelium. By itself the oestrogen increased the percentage of cornified cells in the vaginal smear. The response in groups of animals could be graded with the dose, and 0.2 I.U. divided between two days gave a positive response in 75 per cent. of the animals. The oestrogenic effect of 0.1 I.U. of oestradiol daily for 6 days could be counteracted by the simultaneous administration of 0.15 I.U. vitamin A daily for the last 4 days, but not by 0.015 I.U. daily. With oestradiol the vaginal epithelium almost doubled its thickness and the thickening was not prevented by vitamin A. By itself the vitamin had little effect on the thickness of the epithelium, even when applied in large doses. Histological studies gave no evidence that alkaline phosphatase activity could be correlated with the synthesis of fibrous protein, as has been suggested. Except in the basement membrane, furthest removed from the surface of the epithelium, however, phosphatase appeared to be associated with mucopolysaccharides. Vitamin A decreased the concentration of protein-bound sulphhydryl groups. Vitamin A is thought to be involved in protein anabolism and hence to play a general role in inhibiting the formation of keratin.—T. Moore.

TSCHIRREX, B. Die Schutzwirkung von Vitamin A bei Streptomycin- und Neomycinvergiftung des Gehörorgans. [Protective action of vitamin A in poisoning of the hearing apparatus by streptomycin and neomycin.] *Schweiz. med. Wochenschr.*, 1954, **84**, 1414-1415. [Otorhinolaryngol. Klin., Univ. Zürich.]

A group of about 20 guinea pigs were given daily an intramuscular injection, per kg. bodyweight, of 120,000 "units" vitamin A. After 14 days, while continuing to receive the vitamin, they and a similar untreated group were given subcutaneously, per kg. bodyweight, 300 mg. streptomycin daily for 25 days. The sensitivity to sound of all the animals was tested by the reflex twitching of the ear lobe at a sudden noise. The sound used was the crackling noise made during the charging of a condenser, transmitted through an amplifier, measurement being with a potentiometer. Before the treatment with streptomycin, the hearing of those given vitamin A became more acute than of those not given it. While streptomycin was being given the hearing of both groups deteriorated, but that of those not given vitamin A much the more severely.

When neomycin was given in the same way for 6 days the result was the same, but the deterioration of hearing in both groups was more severe.

REISS, R., GRAFFI, A. and HEBEKERL, W. Über chemische Frühveränderungen der Rattenleber nach Verfütterung cancerogener Azofarbstoffe. 8. Veränderung des Vitamin-A-Gehaltes. [Early chemical changes in rat liver after administration of carcinogenic azo pigments. 8. Changes of vitamin A content.] *Arch. Geschwulstforsch.*, 1954, 7, 321-325. [Inst. Med. Biol., Berlin-Buch.]

For previous parts see Absts. 4798, Vol. 23; 324, Vol. 25.

Vitamin A was estimated by the $SbCl_3$ method in the livers of rats which were given 20 mg. 3'-methyl-4-dimethylaminoazobenzene daily for 4 days or were untreated. The carcinogen appeared to have the surprising effect of raising the concentration of vitamin A. The averages were for males in I.U. per g. liver 1034 and 666 in treated and untreated animals, respectively, and for females 874 and 568.—T. Moore.

GIROUD, A. and MARTINET, M. Fentes du palais chez l'embryon de rat par hypervitaminose A. [Cleft palate in the embryo rat as a result of vitamin A excess.] *C.R. Soc. Biol.*, 1954, 148, 1742-1743. [Coll. de France.]

Albino rats were given from 20,000 to 35,000 I.U. vitamin A daily from the 4th to the 16th day of gestation, and were killed on the 21st day. In 24 pregnancies 65 per cent. of the embryos were totally resorbed. In those pregnancies in which some embryos were retained, 61 per cent. were alive and the remainder dead and in process of resorption. In the survivors there was a high incidence of abnormalities, with cleft palate in 51 per cent. Exencephaly and ocular abnormalities occurred also, but less frequently.—T. Moore.

SMIRNOV, A. M., KUZMETSOVA, Z. N., MAKUSH, L. T. and MILOVIDOVA, E. G. Lechenie telyat, bol'nykh dispepsiei A-gipovitaminoznoi etiologii. [Treatment of calves against dyspepsia caused by vitamin A deficiency.] *Veterinariya*, 1954, 31, No. 9, 49. [Leningrad Vet. Inst.]

The calves were given horses' gastric juice at the rate of from 30 to 60 ml. once to 3 times a day, from 20 to 40 min. before feeding. After from 6

to 12 hr. their condition improved. Where the illness was severe the calves were given also a disinfectant such as disulphan.—H. Scherbatoff.

3421

STRUMPE, A. I. Poliavitaminoz svinei. [Multiple vitamin deficiency in pigs.] *Veterinariya*, 1954, 31, No. 6, 33-37. [Vetbaklab., Kherson Reg.]

Multiple vitamin deficiency occurs chiefly in the winter and spring. The main deficiency in the Kherson region was of vitamin A. The signs at different ages are described; at from 6 to 8 months there is deformity of the bones, with thickening of the joints, softening of the hoof, failure of sight and poor appetite. A full description of the anatomical pathology is given. The sick animals were fed on concentrated, easily digested food. Malted food, whey, buttermilk, infusion of hay, bone meal, germinated seeds, carrots, potatoes and beet were found useful. [It is not stated whether the pigs were cured or not by the treatment.]

H. Scherbatoff.

WAGNER, K. H. Die Bedeutung und der Nachweis der biologischen Wertigkeit des Vitamins A für die Tierernährung. [Significance and demonstration of the biological value of vitamin A in animal nutrition.] *Arch. Tierernährung*, 1954, No. 5, Beilhefte, 270-282. [Med. Akad., Justus Liebig Hochschule, Giessen.]

The need for vitamin A by young farm animals, the possible sources of it and means for detecting deficiency are discussed. The vitamin can be given as carrots, dried lucerne, liver oil, or vitamin A in oil, in emulsions or a dry powder. In powder form the vitamin can be given direct or mixed with bran or with skimmed milk powder. Several commercial concentrates were found to have lost most of their vitamin A. The vitamin in dry form was protected by coating the particles, but intestinal absorption was considerably hindered. Such protected preparations must be tested biologically, since chemical tests may give misleading results.—V. H. Booth.

3423

WORDEN, A. N., BUNYAN, J., DAVIES, A. W. and WATERHOUSE, C. E. The urinary excretion of vitamin A by the dog. *Biochem. J.*, 1955, 59, 527-528. [Cromwell House, Huntingdon.]

In 24-hr. specimens of urine of 4 normal healthy dogs, after extraction by the method of Lawrie *et al.* (Abst. 3452, Vol. 11), vitamin A was estimated by the $SbCl_3$ method with a diffraction-grating spectrophotometer, at different times of year. Expressed as I.U. per 100 ml. the results ranged from 3.75 to 7.5 for a 4-year-old male mongrel

terrier, 2.5 to 24.0 for a 3-year-old male Scotch terrier, 2.7 to 47.5 for a 6-year-old female Cocker spaniel and 1.75 to 12.5 for a 2-year-old male Husky. The total output of vitamin A for the 24-hr. periods ranged from 10.9 to 235 I.U. The significance of these large variations is discussed. No detectable amount of vitamin A was found in a 24-hr. specimen of urine from a cat.

NARAYANAN, K. M., ANANTAKRISHNAN, C. P. and SEN, K. C. **Vitamin A in dairy products. 4. Influence of feed on the stability of vitamin A in ghee on storage.** *Indian J. Dairy Sci.*, 1954, 7, 205-212. [Indian Dairy Res. Inst., Bangalore.]

For earlier parts see Absts. 2943, Vol. 24; 356 and 1865, Vol. 25.

Ghee was prepared from the milk of cows and buffaloes which had been given a diet with a high carotene content, or a low carotene content, or with a supplement of shark liver oil, or of cottonseed or cottonseed cake, or of coconut. The ghee was stored in glass, aluminium, tin or mud containers for 6 months. Analyses were made monthly for vitamin A and carotene, and for the peroxide value of the fat. The carotene intake had little influence on the effect of storage; the peroxide value and loss of vitamin A were higher for the buffalo than for the cow ghee. Shark liver oil did not affect the stability of vitamin A in the ghee, but again the cow ghee was the more stable. After 6 months the loss of vitamin A from the ghee of animals given cottonseed was 4.6 per cent., and 10.7 per cent. from the ghee of those given cottonseed cake. The average loss of vitamin A from the ghee of animals given coconut was 13.7 per cent. Loss of vitamin A and carotene was about the same from samples stored in glass, aluminium and tin containers, being about 2.2, 5.3 and 15.1 per cent., after 2, 4 and 6 months, respectively. When storage was in mud pots, the loss of vitamin A after 2 months was about 75 per cent. and after 3 months it was complete; percentage loss of carotene was 41, 57 and 94 after 1, 2 and 3 months' storage, respectively.

DE, N. K. and KSHIRSAGAR, S. G. **Effect of cooking on the vitamin A values of fortified vanaspati and some foodstuffs of animal origin.** *Indian J. Med. Res.*, 1954, 42, 569-575. [Nutrit. Res. Labs., Indian Council Med. Res., Coonoor, S. India.]

Vanaspati, hydrogenated groundnut oil, was fortified by addition of a preparation of vitamin A acetate so that the final product contained between 8 and 45 I.U. vitamin A per g. On heating part

of the sample to 100° C. in an open aluminium vessel over a bunsen burner, the vitamin A content per g. fell from 34.0 I.U. to 32.9. Further heating from 100° to 130° for 5 min. resulted in a fall to 30.8 and after heating to 215° the value was only 5.4. No vitamin A was detected in a sample heated for 3 min. at 225°. In different dishes in which the fortified vanaspati was added to semolina, onions, potatoes and other vegetables, loss of vitamin A on cooking varied from 8 to 69 per cent. Ghee, made from buffalo milk, when fried with potato wafers lost 74 per cent. of its vitamin A. Percentage loss of vitamin A on cooking sheep's liver curry in a large open vessel ranged from 23 to 48, but was only 3 when the liver was boiled in water for 15 min. When egg omelettes were prepared by shallow frying, percentage loss of vitamin A was 37, but the loss was 74 in deep frying. Despite the large loss of vitamin A when fortified vanaspati is cooked, it is considered that the amount which remains makes a material contribution to the diet.—I. M. Sharman.

AURE, L. **Vitamin A i innvoller av torsk og sei. [Vitamin A in the internal organs of cod and coalfish.]** *Fiskeridirektoratets Skr. Ser. Teknol. Undersøk.*, 1951, 2, No. 1, pp. 12. English summary.

Data are presented for weights of fish and of their liver and caeca, fat in these, and vitamin A content of the caecal fat. On the average of 24 fish, caecal oil from Lofoten cod had 28,900 I.U. per g., equivalent to 525 I.U. per g. caecal substance. Caeca preserved by boiling, pressing and acidifying with HCl, or in pickle, had the same average value. Stomach, intestine, roe and milt from Lofoten cod contained much less, the intestine 27 to 32 I.U. per g. or 2900 to 3500 I.U. per g. oil.

Caeca from fjord cod contained per g. caecal substance 410, from coalfish 800 or 1260 and from salmon 1700 I.U.; per g. caecal oil in the same order 21,700, 21,400 or 54,000, and 9500 I.U.

BICKOFF, E. M., LIVINGSTON, A. L. and THOMPSON, C. R. **Bisphenol derivatives as antioxidants for carotene.** *J. Amer. Oil Chem. Soc.*, 1955, 32, 64-68. [W. Utilisation Res. Branch, U.S. Dept. Agric., Albany 6, Calif.]

The effect of changes in the molecular structure of different bisphenols on their power to stabilise an oil solution of carotene was determined. A methylene or S link between the phenolic nuclei gave efficient anti-oxidants, which were most effective when the hydroxyl groups were in the ortho-position and somewhat less so when they

N.A. and B., July 1955

were in the *para*-position. The addition of alkyl groups improved efficiency but 3 in one ring almost destroyed it. Activity was decreased by phenyl substitution in the methylene bridge and was almost wholly destroyed by chlorine substitution in the ring. Some of the active substances were effective for stabilising carotene in alfalfa meal but others were of little value.—A. Hepburn.

3428

BICKOFF, E. M., LIVINGSTON, A. L., GUGGOLZ, J. and THOMPSON, C. R. **Alfalfa carotene. Quinoline derivatives as antioxidants for carotene.** *J. Agric. Food Chem.*, 1954, 2, 1229-1231. [W. Utilisation Res. Branch, U.S. Dept. Agric., Albany 6, Calif.]

Thirty-nine quinolines were tested for their power to protect carotene in solution in mineral oil against oxidation. The criterion was the time in hours in which 20 per cent. loss of carotene occurred. The most effective was 6-hydroxy-2:2:4-trimethyl-1:2-dihydroquinoline, which postponed the destruction from 1 hr. in its absence to 155 hr. in its presence. When the same quinolines were tested for their power to prevent the oxidation of carotene in dried alfalfa meal, they were ranked in about the same order as in the test with oil, but protection was much less in the meal. The most effective were 5 alkoxy derivatives. With 6-ethoxy-2:2:4-trimethyl-1:2-dihydroquinoline, for instance, only 40 per cent. of the carotene was lost during storage from meal against 67 per cent. in untreated meal.

The relation between the structure of quinolines and their anti-oxidant activity is briefly discussed. V. H. Booth.

3429

BICKOFF, E. M., THOMPSON, C. R., LIVINGSTON, A. L., VAN ATTA, G. R. and GUGGOLZ, J. **Effect of added animal fats and vegetable oils on stability of carotene in dehydrated alfalfa meal.** *J. Agric. Food Chem.*, 1955, 3, 67-69. [W. Utilisation Res. Branch, U.S. Dept. Agric., Albany 6, Calif.]

Samples of alfalfa meal were treated with 5 per cent. of several vegetable oils, mineral oil and animal fats and yellow greases. After 4 months' storage at 25° C. carotene was estimated. An untreated sample had then lost 53 per cent. of its carotene. Without exception the oils afforded protection; only 10 per cent. of the carotene was lost from meal treated with mineral oil, and from 23 to 30 per cent. from meals treated with plant oils, including peanut, sesame and cottonseed. Animal fats with 5, 15 or even 40 per cent. of free fatty acid were as effective as refined oils.

It is suggested that the fats raised the stability

Vol. 25, No. 3

by bringing carotene and naturally occurring antioxidants in the meal into solution together. The view is supported by the finding that carotene in an extract of dried alfalfa when dissolved in oil was more stable than in the original meal or than pure carotene dissolved in oil.—V. H. Booth.

3430

BOOTH, V. H., COATES, M. E., COX, C. P., THOMPSON, S. Y. and HEALY, M. J. R. **Stability of carotene from dried grass meal and of synthetic vitamin D₃ in chick mash.** *J. Sci. Food Agric.*, 1955, 6, 10-14. [Dunn Nutrit. Lab., Milton Rd., Univ. Cambridge.]

A mash for chickens was prepared by 7 compounds to their own recipes, but with about 5 per cent. of dried grass and 1 I.U. per g. of synthetic vitamin D₃ replacing the cod liver oil normally used. After 16 weeks' storage the average percentage loss of carotene from the dried grass was 8 and from the mash 13.5. In order to assess the antirachitic and vitamin A potency after 16 weeks' storage, 6 groups of 15 cockerels were given the mash unfortified or with 25, 50, 75 or 100 per cent. of it replaced by the fortified mash. The sixth group received the fortified mash with 1 per cent. cod liver oil. At the end of the experiment the tarsometatarsal distance was measured to determine the extent of rickets, and the vitamin A content of the liver was estimated chemically. Addition of only 25 per cent. of the fortified to the unfortified gave normal bone formation. The vitamin A content of the liver ranged from 10 I.U. in the birds receiving unfortified mash to 508 I.U. in those receiving it fortified.—R. J. Ward.

3431

MITCHELL, H. L. and SILKER, R. E. **Effects of antidust oils on stability of carotene in dehydrated alfalfa meal.** *J. Agric. Food Chem.*, 1955, 3, 69-71. [Kansas Agric. Exp. Stat., Manhattan.]

Vegetable and animal oils with the anti-oxidant 6-ethoxy-1:2-dihydro-2:2:4-trimethylquinoline were applied in a mixture of acetone and light petroleum to alfalfa meal so as to give a final quinoline concentration of 0.02 or 0.05 per cent. in the meal. Carotene in all samples, including controls, was estimated after storage under standardised conditions. Oil or grease in a concentration of 0.8 per cent. with no quinoline had little or no effect on carotene retention during storage. Some oils applied at the rate of 4 per cent. of the sample weight protected the carotene. Untreated meal, for instance, lost 61 per cent. of its carotene, whereas meals treated with cottonseed oil or white grease lost 45 and 35 per cent., respectively. Salmon body oil slightly increased the loss. The loss was much reduced in each of the oils by the

anti-oxidant, and the greater the amount of anti-oxidant, the greater the effect.

It was confirmed that heating the treated meals resulted in even greater protection. In pellets made from meal treated with quinoline and oil the carotene was more stable than in treated loose meal. The stabilising effect was believed to be the result of the heat produced during pelleting.

Oil with or without quinoline varied considerably in its protective effect on alfalfa meals from different sources.—V. H. Booth.

3432

McCOLLUM, J. P. **Distribution of carotenoids in the tomato.** *Food Res.*, 1955, 20, 55-59. [Dept. Hortie., Univ. Illinois, Urbana.]

The outer pericarp of ripe tomatoes had the best colour and was richest in total carotenoids. The locular contents were richest in carotene, excluding lycopene, but were poorest in colour. The ripest parts of the fruit were richest in carotene. Development begins at the apical end and at early stages the carotene content was highest there. Later, the parts receiving most illumination were richest in carotene. The carotene content was greater in presence than in absence of chlorophyll. When tomatoes are sampled for carotenoids it is recommended that equal opposite sectors be taken to compensate for these variations.

VITAMIN D

3433

NUMEROF, P., SASSAMAN, H. L., RODGERS, A. and SCHAEFER, A. E. **The use of radioactive phosphorus in the assay of vitamin D.** *J. Nutrition*, 1955, 55, 13-21. [Squibb Inst. Med. Res., E.R. Squibb and Sons, New Brunswick, N.J.]

Rats of the Sprague Dawley strain, 21 days old and weighing from 45 to 60 g., were fed on a diet, per cent., of yellow maize 76, wheat gluten 20, CaCO_3 3, NaCl 1, and lysine monohydrochloride 0.5, vitamin in mg. per kg. diet, of vitamin B, 2, riboflavin 4, nicotinic acid 10 and Ca pantothenate 4. The supplements of lysine and B vitamins accelerated the development of rickets. Some rats were examined by the line test to confirm the presence of rickets. When rickets was established the single test dose of vitamin D was given orally in 0.2 ml. maize oil; 48 hr. later from 20 to 25 μC . radio-active P were given by intraperitoneal injection. After administration of vitamin D the rats were given 10 g. of the diet daily for 9 days. The degree of radio-activity was then measured with a Geiger Müller counter, under anaesthesia, in the rat's wrist suitably fixed. Total counts in 2 min. were recorded. The line test was made on the same rats or on groups maintained concurrently without injection of ^{32}P . The results of 14 experiments showed a substantially linear relationship between the log dose and the number of counts per min., and the response curve for any given material resembled that obtained by the line test. The useful range of dosage is said to be from 4 to 16 "units". The validity of the method, originally proposed by Snyder *et al.* (Abst. 4729, Vol. 21), is confirmed. It has the advantage of being quantitative with no subjective element in the assessment.

E. M. Hume.

3434

FRIEDMAN, L. and SHUE, G. M. **Sample preparation in the bioassay for vitamin D.** *J. Assoc. Off. Agric. Chem.*, 1955, 38, 165-172. [Food and Drug Admin., Dept. Health, Educat. and Welfare, Washington, D.C.]

Foods and commercial preparations to be tested for vitamin D are liable to contain other nutrients that may affect healing in the biological test. Recently a further difficulty has been introduced by the incorporation into commercial preparations for human or animal use of vitamin D stabilised by coating the vitamin particles with substances not soluble in fat-solvents, so that complete extraction of the vitamin is very difficult.

Samples of evaporated milk specially fortified and of other materials of known vitamin D content were extracted in a number of ways and the extracts were tested biologically. The most satisfactory modification was the introduction of a saponification procedure with alcoholic KOH. It is described in detail. It did not cause any destruction of vitamin D. Samples of 17 materials were extracted by the U.S.P. method and by the saponification procedure. In every instance but one the values obtained with the latter were higher, and usually substantially higher, than with the former.—E. M. Hume.

ROGERS, A. R. **The spectrophotometric determination of vitamin D in pharmaceutical preparations. 1. Solution of calciferol B.P.** *J. Pharm.*, 1954, 6, 780-784. [Anal. Dept., Allen and Hanburys, Ltd., London.]

A method of estimating vitamin D in calciferol solutions B.P. is described, based on the absorption at 500 m μ . of the colour developed by adding calciferol dissolved in ethylene dichloride to a solution

N.A. and R., July 1955

of 20 per cent. SbCl_3 in ethylene dichloride with 2 per cent. acetyl chloride. Maximum extinction was reached in about 1 min. The method was applied to solutions in oil, the absorption due to the oil being eliminated by graphical extrapolation.—K. H. Coward.

3436

RAOUL, Y., LE BOULCH, N., BARON, C., CHOPIN, J. and GUERILLOT-VINET, A. Isolement du composé anti-rachitique formé au cours de l'action de la floridine sur le cholestérol. [Isolation of the antirachitic substance formed during the action of floridin on cholesterol.] *Bull. Soc. Chim. biol.*, 1954, **36**, 1265-1271. [Lab. Zool. Appl., Fac. Pharm., Paris.]

The preparation is exactly described of an antirachitic substance from cholesterol by boiling it with floridin in CCl_4 . Two substances were produced, one the precursor of the active substance, which was liable to become converted into the second, a stable inactive substance. The precursor was converted into the active substance, called 82, by a procedure including boiling with 5 per cent. methanolic potash, followed by acid extraction and passage through a chromatogram of Brockman alumina. The final product was an oil with absorption max. in the ultraviolet spectrum at 250 μ .

Vitamin D_3 left in solution in light petroleum showed a change in the absorption max. from 265 to 250 μ ., and from the solution the same substance, 82, was obtained as was prepared from cholesterol with floridin. If, at certain steps in the preparation of 82 by either of the means just described, hard water, such as Paris tap water, was used instead of distilled water, an oily substance, 83, was obtained with absorption max. at 265 μ ., and a considerably higher biological activity. It included traces of metals and had a strong affinity for Ca. In an acid medium 83 lost the metals and reverted to 82. Both 82 and 83 have been found in natural products, and their presence complicates any attempt at estimating vitamin D activity by physico-chemical methods. Saponification by transforming them might change the natural vitamin D potency.—E. M. Hume.

ENGELFELT, B. and ZETTERSTRÖM, R. A note on the uptake of radioactive phosphate in the skeleton of rachitic rats. *Acta physiol. scand.*, 1954, **32**, 320-324. [Dept. Phys. Cell Res., Karolinska Inst., Stockholm.]

Male rats, 3 weeks old, received the rachitogenic diet of Steenbock and Black. After 4 weeks they were injected with 0.10 mC. of $\text{Na}_2\text{H}^{32}\text{PO}_4$; some were given 30 I.U. vitamin D_2 3 days previously and some normal rats also were injected. After 1.5, 3 and 6 hr. animals were killed and specific activity was estimated in the blood serum and in the diaphyses and epiphyses separately of the femur and tibia. Specimens of bone were treated with ammonium sulphate and 15 per cent. trichloroacetic acid, which extracted the minerals completely. The portion insoluble in ammonium sulphate but extracted by trichloroacetic acid is referred to as the remaining fraction; it has a much slower rate of renewal than the fraction soluble in ammonium sulphate, which is regarded as coming from the less highly mineralised part of bone.

In the fraction extracted with ammonium sulphate, whether from the epiphysis or diaphysis, the rate of uptake of specific activity was high in all 3 groups, but in the remaining fraction it was much less rapid in both epiphysis and diaphysis of the rachitic rats than of the normal rats or of those given vitamin D; in these last 2 groups it was about the same.—E. M. Hume.

3439

CARLSSON, A. (with LINDQVIST, M. and MAGNUSSON, T.) The effect of vitamin D on the absorption of inorganic phosphate. The cause of hypophosphatemia and hypocalcemia in vitamin D deficiency. *Acta physiol. scand.*, 1954, **31**, 301-307; 308-311. [Dept. Pharmacol., Univ. Lund.]

Rats, 3 weeks old, received a "Ca-free" diet containing 0.04 per cent. Ca and 0.5 per cent. P, with or without CaCO_3 to raise the Ca content to 2.0 per cent. After 3 weeks for those without added Ca and after 5 weeks for those with it, ^{45}Ca and ^{32}P were given as a mixture of Ca lactate and Na_2PO_4 supplying 5, 10 or 20 mg. Ca and 2.5 mg. P. About half the rats in both series were given 100 I.U. vitamin D 3 days before the isotopes. Some of those given the diet without added Ca had another dose of 100 I.U. vitamin D 11 days before the isotopes. The urine and faeces were collected and the rats were killed 18 hr. after the isotopes were given. The percentage of either isotope absorbed was taken to be 100 minus the percentage of the dose found in the gastro-intestinal tract and faeces.

With the "Ca-free" diet, the percentage of Ca or P absorbed was not greatly affected by the

amount of Ca given. The percentage of Ca was nearly doubled when vitamin D was given, and that of P was increased, but less. The increased absorption of P produced by vitamin D could not be attributed to reduction of the amount of Ca in the intestine. With the diet high in Ca, the only dose of Ca given was 5 mg. with 2.5 mg. P; when vitamin D was given the absorption of Ca was increased but that of P was not. With the "Ca-free" diet the growth and wellbeing of the rats was much improved by addition of vitamin D, and it is therefore suggested that the effect on the absorption of P in that experiment was indirect and related in some way to the effect on growth.

Rats, 3 weeks old, were maintained for 6 weeks on the same "Ca-free" diet as in the preceding experiment, with CaCO_3 added to bring the Ca content up to 0.8 per cent. They were then given instead a mixture of, per cent., sucrose 93, NaCl 1 and Ca lactate 6. It contained 0.8 per cent. Ca and no P. After 24 hr. half the rats received 100 I.U. vitamin D. After another 3 days they were given by stomach tube a few μC . of ^{32}P and 0.3 g. of the sugar and salt mixture. Urine and faeces were collected and after 24 hr. the rats were bled.

With and without vitamin D the dose of P disappeared almost entirely from the gut and the amount in the urine did not increase, but with vitamin D the amount in the blood serum increased from 3.6 to 5.6 mg. per 100 ml.; the amount in the tibia and fibula increased also and that in the incisor teeth decreased slightly. It was concluded that without vitamin D rats could not utilise their bone stores and, to test the conclusion, rats which had been maintained up to 70 days of age on the diet with a satisfactory ratio of Ca to P were transferred to the "Ca-free" diet for 24 hr., and were then bled; half of them had been given 100 I.U. vitamin D 3 days previously. In spite of well filled bone stores, the respective Ca and P values, in mg. per 100 ml. serum, were 6.9 and 8.7 for the rats not given vitamin D, and 9.4 and 8.7 for the rats given vitamin D, compared with 8.0 and 7.3 for rats on the original well balanced diet. Failure to utilise bone stores in absence of vitamin D was thus held to be further confirmed.

CARLSSON, A. (with LINDQVIST, M. and MAGNUSSON, T.) The influence of vitamin D on the uptake of ^{35}S -labelled sulfate in the bones. *Acta physiol. scand.*, 1954, **31**, 312-316. [Dept. Pharmacol., Univ. Lund.]

Groups of 4 or 5 rats, 2 months old, were given a diet containing 0.5 per cent. P and 0.04 per cent. Ca, or the same with CaCO_3 to bring the Ca percentage up to 0.8 or 2.0. A single oral dose of

100 I.U. vitamin D_2 was given to some rats on each diet 3 or 4 days before intraperitoneal injection of 50 μC . of ^{35}S as carrier-free, inorganic sulphate. The rats were killed 16 hr. later.

In the pooled femur, tibia and fibula of both legs, increased uptake of ^{35}S was associated with administration of vitamin D in the groups on the 2 diets of lower Ca content, but with the highest Ca content there was no difference. Raising the Ca content of the diet to 0.8 per cent. from 0.04, without vitamin D, had the same effect. The treatments which increased ^{35}S uptake in the bones promoted appetite and growth. When intake of the diet with 0.8 per cent. Ca was reduced for the rats given vitamin D to that of the rats not given vitamin D, the difference in the ^{35}S content of the bones disappeared. The ^{35}S content of the urine was not significantly affected by the different treatments.—E. M. Hume.

3441

CARLSSON, A. and HOLLUNGER, G. (with LINDQVIST, M. and MAGNUSSON, T.) The effect of vitamin D on the citric acid metabolism. *Acta physiol. scand.*, 1954, **31**, 317-333. [Dept. Pharmacol., Univ. Lund.]

The "Ca-free" diet containing 0.04 per cent. Ca and 0.5 per cent. P (see Abst. 3439) was used, and the Ca and P contents were raised by adding CaCO_3 and $\text{NaH}_2\text{PO}_4 \cdot 2\text{H}_2\text{O}$. Rats 3 weeks old were maintained for 3 weeks on the diets. A single dose of 100 or 100,000 I.U. vitamin D_2 was given at varying intervals before the rats were killed. Ca, P and citric acid were estimated in the blood serum, and Ca and citric acid in the tibia and fibula and 4 incisors. Citric acid was estimated by the pentabromoacetone method modified by using *m*-hydroxybenzoic acid instead of H_2O_2 .

Vitamin D caused citric acid to increase in the serum and bones with all the diets used. With a favourable ratio of Ca to P in the diet, a rise occurred in the serum within 24 hr., but could not be detected so soon in the bone. With the diets low in Ca or P the rise was less rapid. The rise in the serum was preceded by a slight drop which occurred sooner with the large dose of vitamin D. With the diet low in Ca, the serum Ca value reflected the citric acid value, and with the diet low in P the serum P value did so. When both minerals were sufficient and the ratio was correct, the serum values for both minerals behaved like the citric acid value, the effect on the P value being the greater. The early drop in the citric acid value was shown also by the Ca or P or both values.

To some animals 100 I.U. vitamin D_2 were given 3 times a week for 3 weeks. The effect in raising the citric acid content of the serum and bones was more marked in the rats having the diet low in Ca.

N.A. and R., July 1955

The values for serum Ca and P were varied by maintaining the rats for 3 weeks on diets of different Ca and P content without any vitamin D. Raising the P content of the serum seemed to have little effect on the citric acid content of the bones or serum, but raising the Ca value in the serum increased both. The change was, however, much slower than that induced by vitamin D, so that it seemed improbable that the effect of vitamin D on citric acid was indirect through the effect on Ca.

The provisional conclusion was reached that vitamin D acts primarily by promoting the production of citric acid in the bones, and that the influence of the vitamin on the bone salt is thus explained.—E. M. Hume.

3442

SOBEL, A. E. and BURGER, M. **Calcification. 13. The influence of calcium, phosphorus, and vitamin D on the removal of lead from blood and bone.** *J. Biol. Chem.*, 1955, **212**, 105-110. [Dept. Biochem., Jewish Hosp. Brooklyn, N.Y.]

Rats aged from 23 to 25 days were fed on a stock diet containing 0.8 per cent. lead as basic lead carbonate. After 29 days 3 groups were made and given diets without lead, low in Ca and P, or high in Ca and low in P, or low in Ca and high in P; half the rats in each group were given 100 I.U. vitamin D daily. After 18 days they were killed. Ca and P were estimated in the serum, lead in the whole blood, and lead and ash in the femur. The lead concentration in the blood was inversely related to the concentration of P in the serum, and was, therefore, highest in the rats having the diet high in Ca and low in P, without vitamin D; the total amount of lead in the bone was lowest in the same group. The blood concentration of lead was lowest with the diet high in P and low in Ca, with vitamin D. Such a diet might, therefore, be used in acute lead poisoning to reduce the blood concentration from a dangerous height. When the aim is to remove lead from the bones, the diet high in Ca and low in P, without vitamin D, is the most suitable.

NESENT, R. and GASTMEIER, W. **Wachstumssteigerung durch Vitamin D. [Stimulation of growth by vitamin D.]** *Arch. Tierernährung*, 1954, No. 5, Beihefte, 234-243. [Inst. Tierzuchtforsch., Rostock-Dummerstorf.]

Three groups of 10 pigs were given for 112 days from the time they could eat, a diet including 1 litre skimmed milk daily. One group received 1000 I.U. vitamin D₂ daily in the milk, amounting in all to about 90,000 I.U.; another group received 3 injections of vitamin D₂ at monthly intervals,

amounting in all to about 225,000 I.U. The third group had no treatment. The rate of weight increase was superior in the group given vitamin D in milk; injection of vitamin D conferred little benefit. Feed utilisation and quantity of meat at slaughter did not differ greatly between the groups.

In a second similar experiment with 3 groups, one group of 11 young pigs received a vitamin D preparation, Mykostin, containing irradiated dried yeast to give 10,000 I.U. vitamin D₂ daily instead of the injection given in the first experiment. Some slight superiority was again shown by the pigs having vitamin D in milk or as Mykostin, but it is recognised that larger numbers and a statistical analysis of the results are necessary before reliable conclusions can be drawn.

NESENT, R., ALTENKIRCH, W. and OTTO, E. **Wachstumssteigerung durch Vitamin D. 2. Versuche mit Hammeln. [Stimulation of growth by vitamin D. 2. Experiments with wethers.]** *Arch. Tierernährung*, 1954, **4**, 258-264. [Inst. Tierzuchtforsch., Rostock-Dummerstorf.]

Groups of merino wethers had been maintained on a diet consisting, in kg. per 100 kg. bodyweight daily, of oat straw 1, Troblako 1, sugar-beet slices 1, oats 0.5, soya grits 0.2 and rapeseed 0.2. The diet contained Ca 22 g. and P 14.4 g. per 100 kg. bodyweight daily. It appeared to be mildly rachitogenic. Groups of from 4 to 6 of the wethers were maintained further on the diet in stall, and were given in addition for 80 days a single injection of 270,000 I.U. vitamin D₂ in oil, or a teaspoonful daily of Mykostin, containing minerals and irradiated yeast, or no addition. The percentage weight increase and the feed utilisation in g. digestible protein per kg. weight increase were, respectively, for vitamin D₂ 35.6 and 836.6, for Mykostin 31.6 and 917.2, and for no supplement 25.6 and 1113.4, but the differences were not significant. There were small differences in the composition of the carcass.—E. M. Hume.

HANSSLER, H. **Untersuchungen über die Wirkung sehr hoher Vigantolgaben bei verschiedenen Kostformen. [Effect of massive doses of Vigantol with different types of diet.]** *Ztschr. Kinderheilk.*, 1955, **76**, 33-38. [Kinderklin., Univ. Tübingen.]

Seventy-eight rats weighing from 35 to 50 g. were used in experiments with Steenbock's rachitogenic diet No. 2965, low in P, to which Ca was added until the Ca content was 4 times the P content, and with a diet (György diet No. 2,

Klin. Wochenschr., 1930, p. 102) whose Ca content was only one-quarter that of the Steenbock diet. The amount of vitamin D given was 1 or 5 mg. daily, or 2 mg. every other day. With the high-Ca diet and 1 mg. vitamin D daily all the rats were dead or dying within 8 days; they had heavy deposits of Ca in the kidneys and heart muscle. With the same diet and 5 mg. vitamin D daily the outcome was even more rapidly fatal. With the low-Ca diet and 1 mg. vitamin D daily the rats showed no untoward effect, but when 2 mg. were given every other day the results were almost as unfavourable as with the high-Ca diet and 1 mg. daily. An increase in the size of the nuclei in the parathyroid glands was attributed to toxic injury and not to excessive activity of the glands.—E. M. Hume.

3446

BRUNE, H. and EGER, W. Der Einfluss von Adsorbentien (Bolus alba) auf wachsende Ratten bei der chronischen Vitamin D₂-Vergiftung: Das Verhalten des Knochens und innersekretorischer Drüsen, insbesondere der Epithelkörperchen, untersucht mittels chemisch-analytischer, histologischer und röntgenologischer Methoden. [Effect of adsorbents (bolus alba) on growing rats during chronic poisoning with vitamin D₂: behaviour of the bones and endocrine glands, especially the parathyroid glands, studied by chemical, histological and X-ray methods.] *Arch. Tierernährung*, 1954, No. 5, Beihefte, 244-269. [Inst. Tierphysiol., Univ. Göttingen.]

Six groups of 30 rats, 30 days old, were maintained for 5 weeks on a diet of natural foods having a percentage content in the dry diet of Ca 0.882, Mg 0.176 and P 0.949. Vitamin D₂ in ethanol was given daily by stomach tube. One group received ethanol only. At the end of the third week, vitamin D administration was stopped for 2 days and 100 I.U. vitamin A was given. The amount of vitamin D₂ given daily ranged from 5000 to 15,000 I.U. in 4 groups of which 2 received 0.8 g. bolus alba daily. One group had the parathyroid glands removed and received 5000 I.U. vitamin D₂ daily for 1 week, and 7500 daily for the rest of the time, but no bolus alba. Rats from each group were killed every week for examination.

The group without vitamin D was the only one which increased much in weight. More animals died in the groups given bolus alba than in the other groups. Histological and X-ray examination and analysis of the bones showed the changes due to vitamin D excess to be more severe in the rats given bolus alba than in the others. The parathyroid glands of the untreated animals increased in weight with their growth, but in the other groups there was no increase and even finally a loss,

particularly in the rats given the largest doses of vitamin D with bolus alba. The nuclei in the parathyroid glands were measured, and the range of size for 200 nuclei was determined each week in 2 of the untreated animals; the size increased with lapse of time. With vitamin D excess the nuclei were smaller and more so when bolus alba was given. The effects of parathyroidectomy were largely counteracted by excess of vitamin D.

It is concluded that bolus alba promoted the absorption of vitamin D and increased the severity of the toxic signs.—E. M. Hume.

HIBBS, J. W. and POUNDEN, W. D. Studies on milk fever in dairy cows. 4. Prevention by short-time, prepartum feeding of massive doses of vitamin D. *J. Dairy Sci.*, 1955, 38, 65-72. [Dept. Dairy Sci., Ohio Agric. Exp. Stat., Wooster.]

In the years, 1947-53, Jersey cows which had had at least 2 previous lactations, and most of which had previously had clinical signs of milk fever, were given, for from 3 to 8 days before parturition, vitamin D in amounts of from 5 to 30 million U.S.P.U. daily as irradiated dried yeast or irradiated ergosterol.

Of 14 cows given 20 or 30 million U.S.P.U. daily, none developed milk fever; of 12 given 10 million one did so, and of 5 given 5 million, also one. Of 22 cows given no vitamin D, which had previously had milk fever, 14 developed it, and of 50 given no vitamin D, which had previously not had milk fever, 27 developed it. Estimations for some cows were made of serum constituents during the week before and the week after parturition. With all the doses of vitamin D, serum Ca and serum P were better maintained before and after parturition than in untreated cows. In samples of butterfat from a few of the cows given 30 million U.S.P.U. vitamin D daily for 7 days before parturition, the mean vitamin D content in I.U. per g. was on the first day of lactation 300, on the 3rd and 4th day 93, and on the 6th and 7th 55.

It is concluded that administration of 30 million U.S.P.U. vitamin D daily for at least 3, and not more than 7, days before parturition and for one day after it, is a safe and effective means of preventing milk fever, but the minimum effective dose was not accurately determined.—E. M. Hume.

NAIR, P. P. and MAGAR, N. G. **Colorimetric determination of vitamin E.** *Indian J. Med. Res.*, 1954, **42**, 577-584. [Dept. Biochem., Inst. Sci., Bombay.]

To 1 ml. of a solution containing not more than 150 μ g. α -tocopherol were added 2 ml. of a 0.2 per cent. phosphomolybdic acid solution in glacial acetic acid. The reaction mixture was diluted with 3 ml. pure ethanol exactly 5 min. later, and the intensity of the yellowish green colour developed was measured in a photo-electric colorimeter with a red filter. The colour was stable for about 20 min. A recovery experiment made by adding known amounts of tocopherol to an unknown amount of tocopherol from shark liver oil showed that with the phosphomolybdic acid reagent about 102 per cent. of the tocopherol was recovered. A spectrophotometric study of the colour reaction showed two maxima at 490 and 725 μ . Calciferol, carotenoids, cholesterol and vitamin A had no effect on the colour reaction. Estimation of the vitamin E in 5 specimens of fat from shark liver oils by the present method gave an average value of 1.69 mg. per g., compared with 1.67 by the FeCl_3 $\alpha\alpha'$ -dipyridyl method. When the liver oil was saponified, without the use of an anti-oxidant, the present method gave an average value of 1.33 mg. per g., and the $\alpha\alpha'$ -dipyridyl method gave an average of 0.346 when the oil was untreated and 0.661 after the removal of sterols.—R. J. Ward.

TAPPEL, A. L. **Studies of the mechanism of vitamin E action. 3. In vitro copolymerization of oxidized fats with protein.** *Arch. Biochem. Biophys.*, 1955, **54**, 266-280. [Dept. Food Technol., Univ. California, Davis.]

It was desired to study the formation of yellow-brown copolymers with properties like those of the pigments characteristic of vitamin E deficiency.

An emulsion of an unsaturated lipid, either linoleic acid or cod liver oil, was made to react with the oxygen of the air and one of the amino-compounds sodium caseinate, bovine serum albumin, egg albumin, casein hydrolysate or glycine, in the presence of one of the catalysts haemin, cytochrome c or haemoglobin, or of one of the inhibitors α -tocopherol, nordihydroguaiaretic acid, propyl gallate, di-*t*-butyl-*p*-cresol or butylated hydroxyanisole. Cytochrome c and haemoglobin significantly increased the rate of copolymer formation over that brought about by autocatalysis, when the reactants were linoleic acid and caseinate, and all the three haematin compounds gave large increases in the rate of copolymer formation from the mixture of cod liver oil and caseinate. Copolymer was formed when linoleic acid or cod liver oil reacted with haemoglobin without the presence of caseinate. The amount of copolymer formed was found to increase as the molecular weight of the N source increased from amino-acid to protein hydrolysate and protein. The inhibition of copolymer formation was studied with the cod liver oil and aqueous caseinate emulsion, with haemoglobin as catalyst. α -Tocopherol was considerably less effective as an inhibitor of copolymer formation than the other phenolic anti-oxidants tested.

3453

MILLER, R. F., SMALL, G. and NORRIS, L. C. **Studies on the effect of sodium bisulfite on the stability of vitamin E.** *J. Nutrition*, 1955, **55**, 81-95. [Agric. Exp. Stat., Cornell Univ., Ithaca, N.Y.]

When day-old chicks were given a basal diet which contained mixed tocopherols and alpha-protein from soya bean, 26 per cent. died and 58.9 per cent. had exudative diathesis. Addition of 6 per cent. brewer's yeast reduced the mortality to 8.6 per cent. and exudative diathesis did not occur. The substitution of tocopheryl acetate for mixed tocopherols reduced the mortality to 6.7 per cent., as did the substitution of starch for Cerelese. When the alpha-protein was purified by washing with water, to reduce the sulphite content from about 1 to 0.04 per cent., no death resulted and no exudative diathesis occurred. When 15 chicks were fed on the purified basal diet with 0.1 per cent. added sodium bisulphite, 5 died, 5 had encephalomalacia and 3 had exudative diathesis. With 0.2, 0.3 and 0.4 per cent. added bisulphite there were 14, 15 and 15 deaths, 10, 12 and 11 cases of encephalomalacia and 2, 0 and 0 cases of exudative diathesis. When 0.125 per cent. methylene blue was added to the basal diet with 0.2 per

cent. bisulphite, there was no case of encephalomalacia or exudative diathesis, and rancidity of the diet was prevented. Lecithin, cephalin or sodium bicarbonate added to the basal diet with 0.2 per cent. bisulphite gave a lower incidence of encephalomalacia with more exudative diathesis but had no effect on rancidity. When the basal diet contained unsaturated fat and bisulphite with or without tocopherols, nearly all the chicks developed encephalomalacia and some exudative diathesis, and the feed became very rancid. Hydrogenated fat with bisulphite caused no vitamin E deficiency, and only one chick developed encephalomalacia and 3 exudative diathesis when rancidified fat and bisulphite were used in the diet.—R. J. Ward.

DNINING, J. S. The nature of the creatinuria of nutritional muscular dystrophy in the rat. *J. Nutrition*, 1955, 55, 209-215. [Dept. Biochem., Univ. Arkansas Sch. Med., Little Rock.]

For 70 days weanling rats were given a basal diet with or without vitamin E, vitamin B₆ or both. After an injection, per 100 g. bodyweight, of 10 μ C. of either sodium ¹⁴C-formate or ¹⁴C-methyl-labelled choline chloride, urine was collected for 16 hr. and creatine and creatinine were estimated by the Jaffe reaction. Creatinine and total creatine were isolated as the zinc chloride salt after the addition of carrier, and purified to constant radio-activity.

For the rats injected with radio-active choline the creatine excreted, in mg. per 100 g. bodyweight, by the doubly deficient group was 4.45, by the vitamin-E-deficient group 1.18, by the vitamin-B₆-deficient group 1.82, and by the non-deprived group 0.17. Corresponding creatine values were 2.04, 2.87, 2.20 and 2.70 mg. per 100 g. bodyweight. Creatine specific activity, in counts per min. per micromole, was 159, 72, 69 and 35 for the 4 groups, respectively. When sodium ¹⁴C-formate was injected, the effects of the dietary supplements on bodyweight and on creatine and creatinine excretion were like those obtained with radio-active choline. The specific activity of creatine was again high in the doubly deprived group and again seemed to be related to the quantity of creatine excreted.

It was concluded that the creatinuria which accompanied nutritional muscular dystrophy in the rat was the result of inability of the muscle to retain creatine.—R. J. Ward.

GRAY, D. E. and DeLUCA, H. A. An antagonistic action between vitamin E and alloxan in carbohydrate metabolism of rat diaphragm. *Arch. Biochem. Biophys.*, 1955, 54, 534-540. [Dept. Biochem., Univ. W. Ontario, London.]

Rats of the Sprague Dawley strain were divided into 3 groups and fed on a diet deficient in vitamin E for 4 to 6 weeks, the first group without vitamin E supplement, the second with a maintenance dose of 0.5 mg. tocopherol daily per rat. The third group received excess of the vitamin equivalent to a daily dose of 100 mg. per rat. At the end of the time one animal from each group was killed daily. The diaphragm was removed, divided into 2 approximately equal portions, and washed with an alloxan monohydrate solution at pH 3.5. One portion was subsequently placed in hot 30 per cent. solution of KOH. Oxygen consumption was measured for both tissues and the amounts of glycogen and glucose taken up by the portions were calculated. A separate series of diaphragms were similarly treated except that the alloxan washing was omitted. It was found that in the vitamin-E-deficient rats the alloxan washing inhibited glucose uptake, glycogen synthesis and oxygen uptake. Uptakes of glucose and oxygen were almost normal in diaphragms from rats in the second group which had received sufficient vitamin E, and formation of glycogen was less inhibited. When rats with excess of vitamin E were examined it was found that there was no additional effect.—I. M. Sharman.

GORCO, J. A. and ASENJO, C. F. Effect of methionine, vitamin B₁₂ and α -tocopherol on the growth-promoting and hepatic-necrogenic activity of Puerto Rican *Torula* yeast. *J. Nutrition*, 1954, 54, 427-435. [Dept. Biochem., Sch. Trop. Med., Univ. Puerto Rico, San Juan.]

Male rats weighing 45 g. were given for 4 weeks a basal diet in which *Torula* yeast supplied 18 per cent. protein and which had a methionine content of 0.24 per cent. One group was given the basal diet only, and others received supplements of methionine as from 0.01 to 2 per cent. of the diet, or 2 mg. α -tocopherol a week, or 200 μ g. vitamin B₁₂ per kg. diet or combinations of the 2 last with 0.5 per cent. methionine.

Improvement in growth and efficiency of protein utilisation occurred with 0.05 per cent. methionine

N.A. and R., July 1955

and maximum growth and protein efficiency with 1 per cent. Addition of 2 per cent. methionine retarded growth and reduced protein intake and efficiency. Addition of vitamin B₁₂ increased protein intake and gain in weight. α -Tocopherol alone was without effect, but when given with methionine it improved growth and protein efficiency. Methionine and vitamin B₁₂ quadrupled the weight gain and doubled the protein efficiency. With all 3 together protein efficiency was slightly higher than with methionine and α -tocopherol. Gross hepatic necrosis occurred in animals receiving less than 0.05 per cent. added methionine, and in one instance in a group of rats receiving a supplement of 200 μ g. vitamin B₁₂ per kg. diet.—R. J. Ward.

DINNING, J. S. The role of vitamin E in regulating the turnover rate of nucleic acids. *J. Biol. Chem.*, 1955, **212**, 735-739. [Dept. Biochem., Univ. Arkansas Sch. Med., Little Rock.]

Weanling rats were given a purified diet deficient in vitamin E with or without a supplement of α -tocopheryl acetate rising from 4 mg. a week at the beginning of the experiment to 16 mg. a week after 5 months. At this time individual samples of urine were analysed for creatine, creatinine and allantoin. The rats were then injected with 0.2 ml. per 100 g. bodyweight of a solution of sodium ¹⁴C-formate and were killed 4 hr. later. Samples of liver, small intestine and skeletal muscle were taken for fractionation by the method of Schneider (Title 2915, Vol. 15).

The average bodyweight of the non-deprived rats was 378 g. and of the deprived 336 g. Excretion of creatinine, creatine and allantoin, respectively, in mg. per g. bodyweight daily, was 29.2, 4.7 and 110 for the non-deprived and 28.8, 9.5 and 174 for the deprived. Incorporation of ¹⁴C-formate into the tissue proteins was similar for the 2 groups, but into the nucleic acids, in counts per min. per micromole of phosphorus, for the small intestine, liver and skeletal muscle, respectively, it was 150.5, 14.6 and 10.8 for the non-deprived group and 140.5, 33.8 and 16.5 for the deprived. Incorporation of ¹⁴C-formate into the ribonucleic acid, deoxyribonucleic acid and ribonucleic acid purines of the liver by the non-deprived group was 13.5, 8.5 and 28.3 counts per min. per micromole of phosphorus and by the deficient group 36.2, 12.8 and 82.0.—R. J. Ward.

TENTORI, L., TOSCHI, G. and VIVALDI, G. L'effetto dell'ipertiroidismo sperimentale sulla comparsa di lesioni muscolari nel ratto mantenuto ad una dieta carente di vitamina E. [The effect of experimental hyperthyroidism on the appearance of muscle lesions in rats maintained on a diet deficient in vitamin E.] *Rend. Ist. Super. Sanità, Rome*, 1954, **17**, 106-114. French, English and German summaries.

Of 2 groups of 8 rats given a diet deficient in vitamin E, containing, per cent., casein 29, starch 36, lard 20, dried yeast 9, salt mixture 3.6 and cod liver oil 2, one group received 0.5 per cent. dried thyroid gland. Rats from each group were killed after 2 and 3 months, and the quadriceps, trapezius, pectoralis major and psoas muscles were examined histologically. Degenerative changes were advanced in the group given thyroid, but were absent from those not given it.

In a second experiment the diet contained, per cent., fat-extracted casein 25, starch 51, dried yeast 10, salt mixture 4, lard 10; 1200 I.U. vitamin A and 100 I.U. vitamin D were given separately. One group of 6 rats received the basal diet alone, and 2 other groups received separately 100 mg. thyroid daily by mouth, one of them having in addition 1 mg. α -tocopheryl acetate daily. All were killed after 2 months. The results resembled those in the first experiment. The rats given thyroid had advanced muscle lesions; those not given thyroid and those given thyroid with α -tocopherol had normal muscles.

It is concluded that thyroid accelerated the appearance of the muscle lesions characteristic of vitamin E deficiency, but did not modify the type of lesion.—D. Duncan.

BOMPIANI, G. D. Ricerche sulla ultrastruttura della fibra muscolare striata nella avitaminosi E sperimentale del coniglio. [The ultrastructure of striped muscle fibres of the rabbit deprived of vitamin E.] *Rend. Ist. Super. Sanità, Rome*, 1954, **17**, 1021-1034. French, English and German summaries.

Preparations of psoas muscle from normal rabbits and from rabbits deprived of vitamin E were examined with the electron microscope, fresh and after fixation in 10 per cent. formalin. The myofibrils in deficient muscle were much more easily separated than in normal muscle and required much shorter treatment. The results are illustrated in 18 plates, which are interpreted as showing the effects of deficiency in the partial or total disappearance of myosin, while the disintegration of the actin filaments is ascribed to failure in the polymerisation of their protein constituent.—E. M. Hume.

3462

MULDER, A. G., GATZ, A. J. and TIGERMAN, B. Phosphate and glycogen determinations in the hearts of vitamin E-deficient rabbits. *Amer. J. Physiol.*, 1954, **179**, 246-248. [Dept. Physiol., Stritch Sch. Med., Loyola Univ., Chicago, Ill.]

Littermate rabbits were given a diet deficient in vitamin E with or without a supplement of 50 mg. tocopheryl acetate per kg. bodyweight. After about 4 weeks the deprived group showed a marked loss of weight with muscular weakness and paralysis. Electrocardiograms taken at this time showed inversion of the QRS₁ and QRS₂ waves with subsequent inversion of the axis deviation and reduction in the potential of the P and T waves. The rabbits were killed by a blow on the back of the head or by Nembutal anaesthesia, and the hearts were removed and frozen immediately in dry ice and ether. Comparison with non-deprived rabbits killed in the same way showed that the amount of cardiac glycogen was not modified in vitamin E deficiency. The mean creatine phosphate value in the non-deprived group was 6.1 mg. per cent. compared with 0.9 in the deprived group. No significant difference occurred in the inorganic phosphate and adenosinephosphate fractions of the hearts.—R. J. Ward.

3463

DESSAU, F. I., LIPCHUCK, L. and KLEIN, S. Heart lesions in mice given diets deficient in vitamins E and K. *Proc. Soc. Exp. Biol. Med.*, 1954, **87**, 522-524. [Chem. and Biol. Res. Sect., Amer. Cyanamid Co., Res. Div., Lederle Labs., Pearl River, N.Y.]

Heart lesions were present in mice given a diet containing 0.1 per cent. sulphaguanidine and deficient in vitamins E and K. The lesions included massive capillary haemorrhages, necrosis of the muscle and leucocytic infiltration. The heart remained normal if either vitamin E or vitamin K was supplied.—T. Moore.

3464

LU, F. C., ALLMARK, M. G. and GRAHAM, W. D. The actions of α -tocopherol on mammalian hearts. *Canad. J. Biochem. Physiol.*, 1955, **33**, 21-24. [Food and Drug Labs., Dept. Nat. Health and Welfare, Ottawa, Ont.]

Various esters of dl- or d- α -tocopherol and a compound described as a water-soluble form of d- α -tocopherol were tested for their stimulatory action when injected or infused into isolated rabbits' hearts or into dogs' hearts *in situ*. No significant pharmacodynamic action could be demonstrated, on either the coronary flow or the hearts' contractions.—T. Moore.

3465

MASCARINI GRATTAROLA, M. and BRANCO, L. Azione degli estrogeni naturali e sintetici e della vitamina E sulle galline deponitrici. Effects of natural and synthetic oestrogens and vitamins E on laying hens. *Ann. Sper. agrar.*, 1954, **3**, 1257-1264. [Ist. Zootec. Cascar. Piedmont, Turin.] English summary.

Intramuscular injections of natural folliculin or synthetic stilboestrol increased the egg production of White Leghorn hens in their second laying year, shortened the period of moulting and increased fertility. The folliculin reduced the hatching capacity of the eggs. Injections of vitamin E, as α -tocopherol, did not have any beneficial effect on egg production, and reduced hatching capacity. The method of giving the oestrogens was too expensive to be economically worth while.

3466

TELFORD, I. R., WISWELL, O. B. and SMITH, E. L. Tocopherol prophylaxis in multiple exposure to hypoxia. *Proc. Soc. Exp. Biol. Med.*, 1954, **87**, 162-164. [Univ. Texas Dent. Branch, Houston.]

Rabbits were kept on a diet deficient in vitamin E, on the same diet with supplements of α -tocopherol, or on a stock diet. Resistance to reduced atmospheric pressure was less in the deprived group than in the other two. After 3 periods in the decompression chamber, none out of 20 in the deprived group survived; of 21 given stock diet 5 survived, and of 18 given tocopherol 10.

T. Moore.

3467

TEDESCHI, G. G. and DE CICCO, A. Ricerche sull'azione anti-vitaminica E del timolo, carvacolo, guaiacono. [Antivitamin E action of thymol, carvacrol and guaiaconol.] *Bol. Soc. ital. Biol. sper.*, 1954, **30**, 727-729. [Ist. Fisiol. Gen., Univ. Rome.]

An injection of 50 mg. thymol acetate or carvacrol acetate given to female rats just before mating had no deleterious effect on the subsequent pregnancy or young. Injected with 50 mg. guaiaconol acetate, female rats of 120 g. weight died within a day or two; female rats of 200 g. weight, injected with the same dose just before mating, did not die, but when they were killed 19 days later, the embryos were very small or dead. Injection of the same dose during gestation caused disturbance of gestation and death of the young. Female rats mated 20 days after the injection had normal young. Administration of 10 mg. α -tocopherol at the same time as 50 mg. guaiaconol acetate, just before mating, successfully counteracted the effect of the latter. Injection of 3 spaced doses of 50 mg. guaiaconol acetate caused testicular degeneration in male rats.—E. M. Hume.

N.A. and R., July 1955

VITAMIN K

3468

DODI, B. Vitamina K e sviluppo mammario. [Vitamin K and mammary development.] *Riv. Zootec.*, 1954, **27**, 348-350. [Ist. Zootec. Gen., Fac. Agrar., Piacenza.]

The ovaries were removed from 18 guineapigs at the age of 60 days. After 3 months 5 were killed and complete involution of the mammary parenchyma was found. The remaining 13 were given a mixed diet and divided into 3 groups, untreated or given vitamin K by intramuscular injection until in 70 days they had received a total of 36 or 135 mg. (20,000 or 75,000 Thayer Doisy units). All were then killed.

Macroscopically the only significant difference was the greater length and diameter of the uterus in the treated animals. No difference was evident in the mammary tissue, but microscopically it was seen that in both treated groups there was alveolar development and sometimes secretory activity. There was no significant difference in the degree of mammary development between the 2 treated groups.

The possible bearing of the finding on hitherto unexplained differences in mammary development in dairy cows is discussed.—D. Duncan.

3469

WRIGHT, H. P. and HAYDEN, M. The effect of diet upon the response to oral anticoagulants. *J. Clin. Pathol.*, 1955, **8**, 65-68. [Obstet.

Unit, University Coll. Hosp. Med. Sch., London.]

In order to assess the possible interference of diet in the response of patients to treatment with anticoagulants such as Tromexan and Dindevan, experiments were made on rats receiving diets containing 3 or 31 per cent. of fat with 10 of casein and 5 of yeast. The effect of the anticoagulant on the blood picture and on prothrombin time was slightly greater, and the lethal dose of anticoagulant was less, for rats given the low-fat diet. The differences in response between the 2 groups of rats were less when additional bile salts were given, showing that they facilitated the absorption of the anticoagulant. The rise in prothrombin time in response to anticoagulants was greater in rats receiving antibiotics. In view of the findings, it is considered that the diets of patients receiving anticoagulant treatment should be carefully controlled, especially the fat content.—A. M. Copping.

3470

QUICK, A. J., HUSSEY, C. V. and COLLENTINE, G. E. The effect of bile deprivation in the growing puppy. *J. Lab. Clin. Med.*, 1954, **44**, 909-910. *Proc.* [Milwaukee, Wis.]

It was concluded that an animal deprived of bile can grow and mature, provided vitamins A, K and possibly D are supplied by injection.

VITAMIN B COMPLEX: GENERAL

3471

MARTEN, G. Zur quantitativen, biographischen Auswertung von Vitamin-Chromatogrammen. [Quantitative biographic evaluation of chromatograms of vitamins.] *Internat. Ztschr. Vitaminforsch.*, 1955, **25**, 392-401. [Anst. Vitaminforsch., Potsdam-Rehbrücke.] English and French summaries.

A method for estimating nicotinic acid, riboflavin and vitamin B₁ was developed in which strips from round paper chromatograms were applied to the surface of agar medium in large petri dishes. Full details are given of the method of plotting and calculating the results.

A. M. Copping.

3472

MITOLO, M., DE FELICE, F., RUCCIA, D., TERLIZZI, L., CAMASSA, M. C. and TERLIZZI, F. Elettrocorticogrammi del ratto albino nelle singole avitaminosi del complesso B. [Electrocorti-

cograms of the albino rat deprived of individual members of the vitamin B complex.] *Bol. Soc. ital. Biol. sper.*, 1954, **30**, 484-486. [Ist. Fisiol., Univ. Bari.]

Readings with the electrocorticograph were made on young male rats weighing from 45 to 55 g. at the beginning of the experiment. The rats were maintained on a normal diet, or on a complete purified diet with or without omission of individual B vitamins. In the deprived rats, disturbances in the electrocorticogram appeared early before other signs of deficiency. They disappeared again on treatment with most of the missing vitamins, but not with riboflavin or vitamin B₁₂. With lack of vitamin B₁ there was a definite increase in the amplitude of the cortical wave with a decrease in frequency. With lack of folic acid frequency increased and amplitude decreased. With deprivation of the other B vitamins there was a decrease in both amplitude and frequency.

E. M. Hume.

3473

TRIBE, D. E. and GORDON, J. G. **Choice of diet by rats. 3. The importance of the sense of smell in the choice of diets deficient in the vitamin B complex.** *Brit. J. Nutrition*, 1955, 9, 1-4. [Rowett Res. Inst., Bucksburn, Aberdeen-shire.]

For earlier parts, not numbered, see Absts. 373, 696, Vol. 24. A choice of 2 diets identical except that one lacked the vitamin B complex was given to 7 rats each deprived of its olfactory bulbs. When deprived of B vitamins the rats greatly preferred the diet with the vitamins and when not deprived preference was slight but definite. Since normal rats gave similar results (see Abst. 373, Vol. 24), a sense of smell was concluded not to be necessary for diet selection.—A. Hepburn.

3474

SCHENDEL, H. E. and JOHNSON, B. C. **Studies of antibiotics in weanling rats administered suboptimum levels of certain B vitamins orally and parenterally.** *J. Nutrition*, 1954, 54, 461-468. [Div. Animal Nutrit., Univ. Illinois, Urbana.]

The effect of aureomycin was studied on the response to pantothenic acid, and of penicillin on the response to vitamin B₁, by rats having a purified diet lacking in the vitamin under test. Aureomycin was given as 200 µg. per g. diet to rats receiving 2 or 40 µg. pantothenic acid per g. diet by mouth or 1 or 20 µg. per g. diet by subcutaneous injection. With 1 or 2 µg. addition of aureomycin significantly increased the growth response, but it had no effect with 20 or 40 µg., which was adequate by itself for a full growth response. Inclusion of aureomycin in the diet increased also the amount of pantothenic acid found in the intestinal contents of rats given the small amounts.

Penicillin was given as 50 µg. per g. diet to rats receiving 0.5 or 25 µg. vitamin B₁ per g. diet by mouth or 0.25 or 10 µg. per g. diet by subcutaneous injection. The antibiotic stimulated the growth of rats receiving the suboptimum doses of vitamin B₁ given orally or parenterally but had only a very slight effect with the large doses. The possible mode of action of the antibiotics is discussed in relation to intestinal synthesis, protection and absorption of pantothenic acid and vitamin B₁.

A. M. Copping.

3475

HALEVY, S., DIAMANT, E. J. and GUGGENHEIM, K. **The effect of antibiotics on the metabolism of nicotinic acid, biotin and folic acid in rats.** *Brit. J. Nutrition*, 1955, 9, 57-62. [Lab. Nutrit., Dept. Biochem., Hebrew Univ.-Hadassah Med. Sch., Jerusalem.]

In a previous study (Abst. 379, Vol. 24) the effect of antibiotics was studied on the metabolism of

those B vitamins which are synthesised to a limited extent in the rat intestine. The effect on nicotinic acid, biotin and folic acid, which are abundantly synthesised, was now examined. Rats were given purified diets with aureomycin, oxytetracycline, penicillin or streptomycin. Aureomycin increased the amount of nicotinic acid in the liver, and in rats receiving sulphonamide it increased the excretion of biotin and folic acid in the urine. Oxytetracycline had an effect like that of aureomycin. Penicillin appeared to have no effect on the metabolism of nicotinic acid, biotin or folic acid. Streptomycin reduced the urinary excretion and the liver stores of folic acid, and the biotin content of the urine and faeces. There was no evidence that the antibiotics affected the conversion of folic acid to citrovorum factor.

A. M. Copping.

KON, S. K. and PORTER, J. W. G. **The intestinal synthesis of vitamins in the ruminant.** *Vitamins and Hormones*, 1954, 12, 53-68. [Nat. Inst. Res. Dairying, Univ. Reading.]

3477

BOHMAN, V. R., HUNTER, J. E. and WALKER, L. **Antibiotics and B-vitamins for lambs.** *J. Animal Sci.*, 1955, 14, 111-117. [Dept. Animal Husb., Univ. Nevada, Reno.]

Two trials were made with fattening lambs and one with orphan lambs to compare supplements of 0, 5, 10 and 20 mg. aureomycin per lb. concentrates, with or without supplements of vitamin B complex. None of the treatments improved rate of gain, dressing percentage or carcass grade, and no ill effect was seen.—T. D. Bell.

3478

HALL, A. P., MOORE, J. G. and MORGAN, A. F. **B vitamin content of California-grown avocados.** *J. Agric. Food Chem.*, 1955, 3, 250-252. [California Agric. Exp. Stat., Univ. California, Berkeley.]

Means and ranges for proximate composition and content of vitamin B₁, riboflavin, nicotinic acid, pantothenic acid, vitamin B₆, folic acid and biotin are tabulated for 3 varieties of avocado grown in California in 4 crop years. The methods of analysis were as previously described (Abst. 4212, Vol. 23).

No consistent effect on composition of crop year, time of harvesting, cold storage or ripening at room temperature was found. The chief differences between varieties was in fat content. The varieties Fuerte, Hass and Anaheim (low-fat) had, respectively, mean contents, in mg. per cent., of vitamin B₁ 0.12, 0.09, 0.08, riboflavin 0.22, 0.23, 0.21, nicotinic acid 1.45, 2.16, 1.56, pantothenic

N.A. and R., July 1955

acid 0.90, 1.14, 1.11, vitamin B₆ 0.61, 0.62, 0.39 and folic acid 0.03, 0.04, 0.078, and of biotin 0.055, 0.056, 0.034 μ g. per g. fresh material. Rat growth tests were made with some samples; the results did not always agree with those of the microbiological tests, possibly owing to poor absorption.

Avocados are considered to compare favourably with most fruits and vegetables and certain other foods as a source of vitamin B₁, riboflavin and nicotinic acid, and possibly of the other B vitamins mentioned, but for the last the data are not so far adequate for valid comparisons.—W. M. Deans.

VITAMIN B₁ (ANEURIN, THIAMINE)

3479

GAUDIANO, A. Determinazione della tiamina mediante misura spettrofotometrica del tiocromo. [Estimation of vitamin B₁ by spectrophotometric measurement of thiochrome.] *Rend. Ist. Super. Sanità, Rome*, 1954, **17**, 591-600. French, English and German summaries.

Thirteen sources of error are discussed which make fluorimetric estimation of vitamin B₁ unreliable. Three variations are described of a method for spectrophotometric estimation of the vitamin as thiochrome, after oxidation with alkaline potassium ferricyanide. No standard is necessary, and the procedure requires from 10 to 200 μ g. vitamin B₁, depending on the photometer. D. Duncan.

3480

GAUDIANO, A., TOFFOLI, F. and BOCCACCI, M. Determinazione chimica della cocarbossilasi sintetica. [Chemical estimation of synthetic cocarboxylase.] *Rend. Ist. Super. Sanità, Rome*, 1954, **17**, 498-520. French, English and German summaries.

A method is described for estimating synthetic cocarboxylase purified by paper chromatography, with as solvent either equal parts of isobutanol, pyridine and water, with 1 per cent. acetic acid, or 20 per cent. urea, 85 per cent. formic acid and *n*-propanol in the proportions 1:2:3. Fractions could be estimated quantitatively by estimation of phosphorus or by densitometry or by spectrophotometric estimation of eluted vitamin B₁. Six vitamin B₁ compounds have been found in some commercial cocarboxylase products.—D. Duncan.

BALAKRISHNAN, S. and RAJAGOPALAN, R. Influence of protein quality on the biosynthesis of thiamine in rats. *Indian J. Physiol. Allied Sci.*, 1954, **8**, 111-116. [Dept. Biochem., Indian Inst. Sci., Bangalore.]

Rats weighing between 60 and 80 g. were given diets containing 15 per cent. protein, as casein, whole egg or soya bean protein, with 1.5 μ g. vitamin B₁ per g. diet and other essential vitamins. The urinary and faecal excretion of vitamin B₁ and the faecal and caecal flora were studied. No significant difference was found between the groups to suggest that the nature of the dietary protein had any effect on the intestinal synthesis of vitamin B₁.—A. M. Copping.

3487

BALAKRISHNAN, S. and RAJAGOPALAN, R. Influence of some typical Indian diets on the intestinal flora and thiamine synthesis in rats. *Indian J. Med. Res.*, 1955, **43**, 31-38. [Dept. Biochem., Indian Inst. Sci., Bangalore.]

Four groups of rats were fed on Indian diets of 4 types, the vegetarian rice diet consumed in Madras and Southern India, the fish and rice diet of Bengal, the whole wheat vegetarian diet of Central India and the Punjab, and the ragi and rice diet of the poorer classes of Mysore. The highest weight gain, urinary excretion of vitamin B₁, vitamin B₁ content of the liver and total counts of faecal flora were found in rats given the wheat diet; the results with ragi and rice were almost as good. Weight gain and synthesis of vitamin B₁ were poor with the rice and fish and the vegetarian rice diets.—A. M. Copping.

3488

SAKENA, K. C., GHATAK, S. and AGARWALA, S. C. Inhibition of thiamine synthesis by vitamin B₁₂ in wild strains of *Escherichia coli*. *Experientia*, 1954, **10**, 488-489. [Central Drug Res. Inst., Lucknow.]

In cultures of freshly isolated wild strains of *Bacterium coli* in the glucose and salt medium of Davies and Mingioli (*J. Bacteriol.*, 1950, **60**, 17) addition of vitamin B₁₂ inhibited synthesis of vitamin B₁. With 0.01 µg. vitamin B₁₂ per ml. there was a decrease of 23 per cent. in the amount of vitamin B₁ formed in 24 hr.; with 1.0 µg. per ml. the decrease was 55 per cent. No explanation of the inhibition could be found and the growth of the *Bact. coli* cultures was not affected by vitamin B₁₂ in the medium.—A. M. Copping.

3489

GERSHOFF, S. N. and HEGSTED, D. M. The failure of thyroxine and high-fat diets to modify the rate of thiamine loss from the body. *J. Nutrition*, 1954, **54**, 609-619. [Dept. Nutrit., Harvard Sch. Pub. Health, Boston, Mass.]

Young adult male mice were fed on diets containing 5 or 20 per cent. fat and no vitamin B₁. In another test, the low-fat diet was given with 25 mg. thyroxine per kg. diet. Animals were killed on the first day and at intervals for 20 days. The total vitamin B₁ and cocarboxylase content of the carcass and liver were measured by microbiological methods. Mice on the high-fat diet lost weight less rapidly and survived longer than those on the low-fat diet, and thyroxine hastened weight loss and death. There was, however, no difference in the rate of loss of vitamin B₁ or cocarboxylase from the carcass or liver of the mice on the different diets. It was concluded that the rate of loss of

vitamin B₁ was dependent on the amount originally present in the body and not on the type of diet given during depletion.—A. M. Copping.

3490

COVER, S. and SMITH, W. H. (Jr.) Variation in thiamine and niacin content of raw lamb muscle. *J. Animal Sci.*, 1955, **14**, 173-177. [Dept. Animal Husb., Texas Agric. Exp. Stat.]

Variations previously reported in the B vitamin content of lamb muscle (Abst. 1771, Vol. 17) were further investigated with lambs from 3 experiments on treatment with aureomycin. Aureomycin did not appear to affect the vitamin B₁ or nicotinic acid content of the muscle; significant variations in both were found in muscle from lambs similarly treated. Leg muscle was slightly richer in vitamin B₁ and nicotinic acid than shoulder and breast. The causes of variation could not be resolved.—A. M. Copping.

3491

DE CARO, L., RINDI, G. and PERRI, V. Comportamento del piruvato ematico in ratti ipofisectomizzati ed in avitaminosi B₁. [Behaviour of blood pyruvate in hypophysectomised rats and in vitamin B₁ deficiency.]

DE CARO, L., RINDI, G. and FERRARI, G. Comportamento del piruvato ematico di ratti in avitaminosi B₁, in seguito a surrenectomia. [Behaviour of blood pyruvate in rats deprived of vitamin B₁ after adrenalectomy.] *Bol. Soc. ital. Biol. sper.*, 1954, **30**, 465-468; 468-470. [Ist. Fisiol. Umana, Univ. Pavia.]

Blood pyruvate and the vitamin B₁ content of the tissues were estimated at intervals in rats which were deprived for between 30 and 40 days of vitamin B₁ and of which some had had the pituitary gland removed. In the latter the weight of the adrenal glands was much less than in intact rats. The vitamin B₁ content of the liver, muscle and brain did not fall quite so rapidly, and the pyruvic acid in the blood rose considerably more slowly.

In rats deprived of vitamin B₁, the adrenal glands of some were removed at intervals of up to 22 days, and blood pyruvate and vitamin B₁ in the tissues were estimated 3 or 4 days later. The same estimations were made on non-deprived, intact and adrenalectomised rats. Blood pyruvate was lower in the adrenalectomised rats, whether deprived or not. In the deprived animals the rate of depletion of vitamin B₁ from the tissues did not greatly differ whether they were adrenalectomised or not.

E. M. Hume.

3492

MONFOORT, C. H. The disappearance of pyruvic decarboxylase and α -ketoglutaric decarboxylase

N.A. and R., July 1955

from pigeon muscles on thiamine-deficient diets. *Biochem. biophys. Acta*, 1955, **16**, 219-228; *Arch. internat. Physiol.*, 1954, **62**, 571-572. *Proc. [Lab. Physiol. Chem., Univ. Utrecht, Netherlands.] French and German summaries.*

Homogenates of breast and heart muscle from pigeons receiving a normal cereal diet or purified diets lacking vitamin B₁ were examined manometrically for production of acetoin and succinic semi-aldehyde with or without addition of vitamin B₁ pyrophosphate. The vitamin B₁ pyrophosphate content of the muscles was estimated also. As depletion of vitamin B₁ progressed, anaerobic metabolism of pyruvate to acetoin and of α -ketoglutarate to succinic semi-aldehyde decreased. The α -ketoglutaric decarboxylase activity decreased less rapidly than the pyruvic decarboxylase activity, and the inclusion of sucrose or peanut oil in the diet affected the rate of loss of activity. In extreme deprivation the pyruvic decarboxylase activity of breast muscle was less with fat in the diet than with sucrose. The α -ketoglutaric decarboxylase activity of breast muscle was less also with fat than with carbohydrate. In most pigeons the α -ketoglutaric decarboxylase of heart muscle was less with carbohydrate than with fat in the diet. It appeared that the decarboxylases were not completely lost even when the birds died of vitamin B₁ deficiency. Vitamin B₁ pyrophosphate decreased as deprivation became more severe, but it also was not completely lost.—A. M. Copping.

3493

LORENZI, G. L. and DE BERNARD, B. Studi sulla biochimica dell'ossificazione. 4. Contenuto di coccobossilasi nella cartilagine metafisaria e nel sangue del coniglio in relazione all'età. [*Biochemistry of ossification. 4. Cocarboxylase content of metaphyseal cartilage and blood of the rabbit in relation to age.*]

CASSELLANI, A. and ZAMBOTTI, V. 5. Presenza di succinodeidrasii nella cartilagine metafisaria. [5. Presence of succinic dehydrogenase in metaphyseal cartilage.] *Bol. Soc. ital. Biol. sper.*, 1954, **30**, 451-453; 453-455. [*Inst. Chini. Biol., Univ. Pavia.*]

4. In 19 common rabbits aged from 25 to 30 days, the cocarboxylase activity of metaphyseal cartilage was 43 per cent. less than in 20 common rabbits aged from 10 to 15 days. In 7 Flemish Giant rabbits aged 30 days, which were growing very fast, the cocarboxylase activity was greater than in either of the groups of common rabbits. In blood of the common rabbits, the cocarboxylase activity was less in the younger rabbits.

5. The presence of succinic dehydrogenase was demonstrated with triphenyltetrazolium chloride

in fragments of cartilage from young rabbits by the method of Kun and Abood (Title 111, Vol. 19).

E. M. Hume.

3494

DE BERNARD, B. Contenuto di coccobossilasi nel fegato di animali normali e diabetici dopo trattamento con acido indolil-3-acetico. [*Cocarboxylase content of the liver of normal and diabetic animals after treatment with indolyl-3-acetic acid.*] *Bol. Soc. ital. Biol. sper.*, 1954, **30**, 457-459. [*Inst. Chim. Biol., Univ. Pavia.*]

Cocarboxylase was estimated in the liver of groups of from 10 to 14 male rats weighing about 150 g. One group was given no treatment, one group received daily for 3 days an injection of 10 mg. indolylacetic acid per 100 g. bodyweight; 2 groups were rendered diabetic with alloxan, and one of them was given indolylacetic acid in the same way. Cocarboxylase activity was greater in animals given indolylacetic acid than in those not given it; the difference was statistically significant in the non-diabetic animals but not in the diabetic ones.—E. M. Hume.

NARDOO, D. and PRATT, O. E. Thiamine pyrophosphatase, acid and alkaline phosphatase activity in the chicken brain in vitamin B₁ deficiency. *Biochem. biophys. Acta*, 1955, **16**, 75-81. [*Inst. Psychiat. (Brit. Postgrad. Med. Federation, Univ. London), Maudsley Hosp.] French and German summaries.*

Chicks were maintained from 3 weeks old on a purified diet without vitamin B₁; some of them were given an intramuscular injection of 100 µg. vitamin B₁ daily. When signs of deficiency were established, birds were killed and phosphatases were estimated in the optic tectum by methods described previously (*Biochem. J.*, 1953, **55**, 140). The histological distribution of the phosphatases was examined in frozen sections of brain tissue. In the deficient chicks there was an increase in vitamin B₁ pyrophosphatase and in alkaline phosphatase but no significant change in acid phosphatase. In the brain of the chick a vitamin B₁ pyrophosphatase activated only by Mg⁺⁺ over a narrow range of pH close to 8.4 was found, in contrast with the vitamin B₁ pyrophosphatase of rat brain, which is activated by Ca⁺⁺ as well as Mg⁺⁺ and has activity over a wider pH range, from 6.9 to 9.1.—A. M. Copping.

ERÄNKÖ, O. and HASAN, J. Enzymatic hydrolysis of thiamine pyrophosphate by frozen sections of rat's kidney, adrenal and liver. *Acta pathol. microbiol. scand.*, 1954, **35**, 563-572. [Dept. Physiol., Inst. Occupat. Health, Työterveyslaitos, Helsinki.]

The histochemical technique of Gomori (*Proc. Soc. Exp. Biol. Med.*, 1949, **70**, 7; **72**, 449) was used to study the distribution of phosphatases in sections of kidney, liver and adrenal gland taken from young and adult rats immediately after decapitation, and cut on a freezing microtome. Vitamine B₁ pyrophosphate and glycerophosphate were used as substrates in alkaline and acid solutions. In alkaline solution both substrates gave the same reaction, but in acid solution the phosphatases capable of splitting vitamin B₁ pyrophosphate showed a distribution differing from that of phosphatases able to split glycerophosphate. The results are considered to suggest the existence of an enzyme differing from non-specific acid phosphatase.—A. M. Copping.

3498

VAN HEYNINGEN, R., PIRIE, A. and BLACKWELL, J. Effect of cocarboxylase on the development of galactose cataract in rats. *Brit. J. Ophthalmol.*, 1955, **39**, 37-40. [Nuffield Lab. Ophthalmol., Univ. Oxford.]

The report of Hörmann (Abst. 3285, Vol. 24) that subcutaneous injection of cocarboxylase prevented the development of galactose cataract in rats was investigated with rats on a diet containing 30 per cent. galactose. The rats receiving cocarboxylase were pair-fed with those untreated and care was taken that the diet was homogeneous. No difference in the development of cataract was found between the groups.

The galactose content of lenses from rats receiving the sugar was investigated and it seemed that galactose was able to penetrate the rat lens *in vivo*. Experiments with intact calf lenses incubated with galactose showed that penetration occurred *in vitro* during incubation for up to about 4 hr. and to a maximum concentration of 42 mg. galactose per 100 g. wet lens.—A. M. Copping.

MALAGUZZI-VALETTI, C. and ORABONA, M. L. Azione dell'aureomicina sul beri-beri sperimentale e sull'efficacia terapeutica dell'aneurina. [Effect of aureomycin on experimental beriberi and on the therapeutic efficacy of vitamin B₁.] *Internat. Ztschr. Vitaminforsch.*, 1955, **25**, 402-406. [Clin. Med., Univ. Bari.] German, English and French summaries.

Of 34 pigeons deprived of vitamin B₁, 12 were given no other treatment and 22 had 40 mg. aureomycin daily. One of the untreated birds died within 4 days and the remainder showed acute signs of deficiency between the 16th and 24th days. Eight of them were cured with vitamin B₁ and 3 left untreated died. Of those given aureomycin, 5 showed signs of deficiency in from 16 to 18 days and were cured with vitamin B₁. The remainder were then given 80 mg. aureomycin daily. About the 20th day 6 showed signs of deficiency and were given vitamin B₁; 4 recovered, 1 remained paralysed and 1 died. Eleven birds were left, which continued to receive 80 mg. daily until, within a few days, they too showed signs of deficiency. Vitamin B₁ failed to restore them if 80 mg. had been given for more than a few days, and they died, but a single injection of cocarboxylase restored 5. It is suggested that a large dose of aureomycin interfered with phosphorylation of vitamin B₁.—E. M. Hume.

MOURIQUAND, G., EDEL, V. and CHIGIZOLA, R. Avitaminose B₁, thiamine et dissociation réactionnelle (mesures chronaximétriques). [Vitamin B deficiency, vitamin B₁ and dissociation of reaction (measurements of chronaxie).] *Internat. Ztschr. Vitaminforsch.*, 1955, **25**, 443-447. German and English summaries.

In normally fed pigeons most of the B vitamins including vitamin B₁, arsenic and other toxic substances cause a rise of vestibular chronaxie. It was desired to know whether the same is true for an unbalanced diet. Pigeons were deprived of the vitamin B complex by a diet of polished rice until signs of beriberi appeared. After that stage a rise of chronaxie could not be caused by vitamin B₁ though the signs of beriberi disappeared, or by arsenic. The effect of vitamin B₁ on chronaxie was again apparent when the nutrition of the birds was restored to normal. The so-called dissociation of reaction to vitamin B₁ in the conditions described is discussed, and is attributed to the other deficiencies of the vitamin B complex inherent in a diet of polished rice.—A. M. Copping.

3502

WOOLLEY, D. and MERRIFIELD, R. B. Mise en évidence d'une nouvelle action de la thiamine par l'emploi de la pyrithiamine. [Evidence for a new action of vitamin B₁ from the use of pyrithiamine.] *Bull. Soc. Chim. biol.*, 1954, 36, 1207-1212. [Rockefeller Inst. Med. Res., New York.]

In mice showing severe signs of vitamin B₁ deficiency after administration of pyrithiamine, the cocarboxylase content of the liver and the pyruvate content of the blood did not differ greatly from those of normal mice. It is suggested that pyrithiamine may exercise its antagonistic effect not by inhibiting the cocarboxylase activity of vitamin B₁ but by some more direct action against a second function of the vitamin concerned with the nervous system. Oxythiamine appeared to be antagonistic to the cocarboxylase activity of vitamin B₁. By use of the two antagonists it was, therefore, possible to demonstrate two functions of the vitamin. Tests on administration of pyrithiamine to frogs gave further evidence of its suppression of the antineuritic activity of vitamin B₁.—A. M. Copping.

3503

NELSON, M. M. and EVANS, H. M. Relation of thiamine to reproduction in the rat. *J. Nutrition*, 1955, 55, 151-163. [Inst. Exp. Biol., Univ. California, Berkeley.]

Adult female rats were given diets lacking vitamin B₁ during pregnancy or for from 11 to 22 days before mating and during pregnancy. Of those with no preliminary deprivation, from 97 to 100 per cent. produced litters but the young were dead or of low birthweight. The mothers lost weight and some died during late gestation. When the deficient diet was given for 11 or more days before mating, from 89 to 100 per cent. of the implantations were resorbed and many failed to implant. There was severe loss of weight and high

maternal mortality. Pair-fed rats given vitamin B₁ did not produce normal litters, so that reduction of food intake was an important factor contributory to the failure of reproduction. Injection of oestrone or progesterone or both hormones into deficient rats produced a great improvement in the viability of the young, in spite of a low food intake by the mother.—A. M. Copping.

3504

NABER, E. C., CRAVENS, W. W., BAUMANN, C. A. and BIRD, H. R. The effect of thiamine analogs on embryonic development and growth of the chick. *J. Nutrition*, 1954, 54, 579-591. [Dept. Biochem., Univ. Wisconsin, Madison.]

Chicks were given for 4 days a ration deficient in vitamin B₁ and on the 5th day a single dose of 20 µg. in order to equalise the body reserves of the vitamin. On the 6th day treatment with the vitamin or the antivitamin analogue or both was started. Neopyrithiamine and oxythiamine injected into eggs increased embryonic mortality and reduced hatching capacity. Oxythiamine was most toxic early in embryonic life and sensitivity to its action diminished considerably after the 5th day and continued to diminish after hatching. Neopyrithiamine remained toxic during the entire incubation period. The inhibitory effect of both antagonists was counteracted by simultaneous injection of vitamin B₁ or cocarboxylase. Inhibition ratios of the amount of vitamin required to counteract a given amount of the antivitamin, determined for the 5-day old embryo, were 1 to 10 for vitamin B₁ or cocarboxylase and neopyrithiamine, and 1 to 20 for vitamin B₁ or cocarboxylase and oxythiamine. Neopyrithiamine injected during the later stages of incubation left the hatching capacity almost normal, but the chicks showed signs of polyneuritis and did not survive. With oxythiamine there were no neurological signs, but oedema developed near the site of injection. Growth-inhibition ratios for young chicks were 1 to 4 for vitamin B₁ and neopyrithiamine and 1 to 200 for vitamin B₁ and oxythiamine. The changing effectiveness of the two antivitamins with age is consistent with known changes in developmental metabolism and with the hypothesis that the two antivitamins affect different enzyme systems.—E. M. Cruickshank.

3505

SUOMALAINEN, P. and PIHLGREN, A. M. On the thiaminase activity of fish and some other animals and on the preservation of thiaminase in silage made from fish. *Acta agral. fenn.*, 1955, 83, 221-229. [Zool. Lab., Univ. Helsinki.]

Thiaminase was estimated by a modification of the method of Sealock *et al.* (Abst. 2078, Vol. 13),

of which full details are given, in the gills, liver and intestine of 13 species of freshwater and sea fish and in the spleen of 10 species.

The highest relative activity was found in the ide (*Leuciscus idus*); next came other cyprinid fish, the crucian carp (*Cyprinus carassius*) and the tench (*Tinca vulgaris*). Some fish had none. There were individual differences within the same species. Of the organs examined, the spleen had most activity.

Thiaminase activity was also found in the gills and mid-gut glands of the swan mussel (*Anodonta cygnea*), but not in frogs or crayfish. Rabbit kidney and spleen had some activity.

Fish offal ensiled with alkali or by the A.I.V. method for poultry feed had no thiaminase activity.

W. M. Deans.

ZIZZA, F. Ricerche sulla tiaminasi. 1. pH ottimo della tiaminasi estratta dalla *Venerupis decussata*. [Researches on thiaminase. 1. Optimum pH for the thiaminase extracted from *Venerupis decussata*.] *Bol. Soc. ital. Biol.*

sper., 1954, **30**, 246-247. [Ist. Chim. Biol., Univ. Palermo.]

The enzyme extracted from the lamellibranch mollusc, *Venerupis decussata*, was purified by precipitation with Na acetoacetate. The enzyme was incubated with vitamin B₁ hydrochloride, buffered with Na acetoacetate for pH from 1 to 5, and with phosphate for pH from 5 to 7, at 40° C., for 60 min., after which the vitamin B₁ left in the mixture was estimated. The amount of vitamin B₁ destroyed increased from pH 1 to pH 3.4, then fell up to about pH 5, after which it increased again up to pH 6.2. The second increase is attributed to instability of vitamin B₁ at such high pH, and not to the action of the enzyme.—E. M. Hume.

WORDEN, A. N. and WATERHOUSE, C. E. The effect of environmental temperature on the urinary excretion of riboflavin by the dog. *Brit. J. Nutrition*, 1955, **9**, 5-10. [Cromwell House, Huntingdon.]

When environmental temperature was raised by about 20° F. the volume of urine excreted by 3 adult dogs fed on a standard diet fell to from 1/3 to 1/2 and the concentration of riboflavin in the urine was more than doubled. The total daily amount of riboflavin excreted was significantly greater in 2 of the dogs.—A. Hepburn.

3513

NIEMAN, C. and JANSEN, A. P. Urinary excretion of riboflavin in normal, diuretic, and alloxan-diabetic rats. *Internat. Ztschr. Vitaminforsch.*, 1955, **25**, 448-458. [Lab. Physiol. Chem., Netherlands Inst. Nutr., Univ. Amsterdam.] German and French summaries.

A diet containing 2.6 µg. riboflavin per g. was given to 40 weanling rats in 4 groups, one with no treatment, one with mild alloxan diabetes, one with severe diabetes and one in which diuresis was

N.A. and R., July 1955

induced by administration of urea. The diabetic rats showed increases in urinary volume and in output of riboflavin, but in simple experimentally induced diuresis the increase in volume was not accompanied by a large increase in output of riboflavin. It is suggested that in alloxan diabetes some mechanism operates to cause displacement of riboflavin.—A. M. Copping.

3514

TEDESCHI, G. G. Eliminazione dell'acido lattoflavinfosforico attraverso le vie biliari. [Elimination of riboflavin phosphate through the bile.] *Bol. Soc. ital. Biol. sper.*, 1954, **30**, 30, 663-665. [Ist. Fisiol. Gen., Univ. Rome.]

In 5 dogs weighing about 10 kg., a cannula was inserted into the bile duct under Pentothal anaesthesia, and the riboflavin solution under investigation was introduced into a vein in a loop of the intestine. Bile was drawn off for an hour, and riboflavin in it was investigated chromatographically. Normal bile contained traces of free riboflavin. Riboflavin that had been injected in the free form scarcely appeared at all in the phosphorylated form in the bile. When phosphorylated riboflavin was injected, it appeared in the bile to a small extent as nucleotides and to a large

extent as free riboflavin. Four spots representing other flavin derivatives appeared also in the chromatogram.—E. M. Hume.

3515

GUARESCHI, C. and ANICHINI, C. Sull'azione antitumorale di alcuni complessi fosfo-riboflavin-metallici. [Action antagonistic to tumours of certain phospho-riboflavin-metal complexes.] *Bol. Soc. ital. Biol. sper.*, 1954, **30**, 752-755. [Ist. Zool., Univ. Cagliari.]

Phospho-riboflavin-metal complexes, described elsewhere (*G. ital. Chemoterap.*, 1954, **1**, 214) and called L', L'' and R, appeared to have some effect in causing regression of benzpyrene sarcoma in rats. On tissue cultures of chicken's myocardium in plasma with embryo juice, the substances had an unfavourable action, causing the cells to lose their power of multiplication.—E. M. Hume.

NICOTINIC ACID (NIACIN)

3517

KOEPE, O. J. and HENDERSON, L. M. Niacin-tryptophan deficiency resulting from imbalances in amino acid diets. *J. Nutrition*, 1955, **55**, 23-33. [Div. Biochem., Noyes Lab. Chem., Univ. Illinois, Urbana.]

Male weanling rats, on reaching a weight of 45 g., received a diet containing, per cent., a mixture of pure amino-acids 18 (see Abst. 3676, Vol. 19), salts 4, nicotinic-acid-free vitamin mixture 2 (see Abst. 4260, Vol. 23), maize oil 5, and sucrose to 100. The tryptophan was reduced to 0.10 or 0.11 per cent. of the DL-form, but all other essential amino-acids, except the one under study, were present in concentration equal to, or greater than, that recommended by Rose (Abst. 5316, Vol. 7).

When the DL-threonine in the diet, of which the optimum percentage is 1.0, was reduced to 0.5, 0.6, 0.7, or 0.8 per cent., the average weight increase over 4 weeks was 15, 30, 21 or 10.5 g.; in the last case addition of 2.5 mg. per cent. of nicotinic acid raised it to 63 g. Results were similar in tests with L-lysine, of which the optimum percentage is 1.24; when the concentration was raised from 0.3 to 0.5 per cent., the weight increase changed from 26 to 31 g.; with 0.6 per cent. it fell to 12 g., but was raised to 55 g. by addition of nicotinic acid.

It is concluded from the results that, with the lowest concentration of either of the essential amino-acids, threonine and lysine, growth was limited by the one lacking, and that the tryptophan present, 0.1 per cent., served as a source of nicotinic acid when its use for protein formation was thus inhibited. Similar, but less consistent, results were obtained in corresponding trials with leucine and isoleucine in concentrations below the optimum.

When 10 per cent. gelatine was included in the diet, supplemented with 0.1 per cent. tryptophan and suitable concentrations of essential amino-acids known to be missing, inclusion of 5 per cent. of threonine depressed growth, and the depression was counteracted by addition of nicotinic acid. The loss of appetite which accompanied reduced food intake in nicotinic acid deficiency was shown by paired feeding experiments to be largely responsible for the suppression of growth observed when threonine was added to a diet containing protein as 9 per cent. casein with 0.2 per cent. cystine.—H. Chick.

3518

SEN, S. C. and SEN, S. Effect of niacin on the calcium level of blood. *Indian J. Med. Res.*, 1954, **42**, 605-612. [Dept. Physiol., Presidency Coll., Calcutta.]

The effect on healthy rabbits of intramuscular injection of 25, 50 or 100 mg. nicotinic acid was studied. A dose of 100 mg. caused a rise in blood Ca which coincided with a rise in blood sugar, maximum values occurring within 30 min. and returning to normal after 2 hr. Blood inorganic P fell. The lower doses of nicotinic acid did not affect blood Ca and had only a small effect on blood sugar.—A. M. Copping.

3519

BANERJEE, S. and BASAK, R. Nicotinic acid metabolism in the rhesus monkey. *J. Nutrition*, 1955, **55**, 179-184. [Dept. Physiol., Presidency Coll., Calcutta.]

Nicotinic acid, nicotinamide, nicotinic acid, N-methylnicotinamide, 6-pyridone, trigonellin and quinolinic acid were estimated in urine from 4 female rhesus monkeys receiving an adequate basal diet. After a preliminary test with no treatment, the effects of giving sulphaguanidine, nicotinic acid or tryptophan were studied. With sulphaguanidine there was a slight decrease in excretion of N-methylnicotinamide, but no other change. With nicotinic acid or tryptophan increases occurred in excretion of N-methylnicotinamide, 6-pyridone and quinolinic acid. Excretion of trigonellin was not affected, and it does not appear to be an end-product of nicotinic acid metabolism in monkeys.—A. M. Copping.

3520

BURCH, H. B., STORVICK, C. A., BICKNELL, R. L., KUNG, H. C., ALEJO, L. G., EVERHART, W. A., LOWRY, O. H., KING, C. G. and BESSEY, O. A. Metabolic studies of precursors of pyridine nucleotides. *J. Biol. Chem.*, 1955, **212**, 897-907. [Dept. Chem., Columbia Univ., New York.]

Nicotinic acid, nicotinamide and 3-hydroxy-methylpyridine tartrate were equally effective as precursors of diphosphopyridine nucleotide in rat erythrocytes and they gave similar gains in weight. Nicotinamide produced 15 times as much N^1 -methylnicotinamide in the urine as nicotinic acid did, and the others produced $2\frac{1}{2}$ times as much. With a deficiency of precursors gains in weight were small, with reduction of pyridine nucleotides in the blood cells and liver, of N^1 -methylnicotinamide in the serum and urine, and of nicotinic acid in the urine. Serum N^1 -methylnicotinamide seemed to reflect most rapidly the decreased intake. L-Tryptophan maintained gains in weight similar to those obtained with nicotinic acid but with it diphosphopyridine nucleotide in the red and white blood cells and liver, N^1 -methylnicotinamide in the serum and urine, and nicotinic acid in the urine were much less.

A. Hepburn.

3521

PORCELLATI, G. Contributo sperimentale sull'amidazione *in vitro* dell'acido nicotinic. [Amidation *in vitro* of nicotinic acid.] *Bol. Soc. ital. Biol. sper.*, 1954, **30**, 642-644. [Inst. Chim. Biol., Univ. Naples.]

The spectrophotometric method of Hughes and Williamson (Abst. 1789, Vol. 24) for estimating nicotinic acid and nicotinamide when present together was slightly modified. In homogenates of liver, kidney and brain of rats, the percentage of added nicotinamide detected by the method ranged from 94.2 to 105.1. When Na nicotinate was added to homogenates of the same organs, suitably buffered and with $MgCl_2$ and NH_4Cl added, nicotinamide, estimated by the spectrophotometric method, was formed in amounts corresponding with the quantity of nicotinate which disappeared. The extent of the conversion was greater when adenosinetriphosphate also was present in the system.—E. M. Hume.

3522

ARRIGO, L. and RICCI, C. Nicotinamide e lipidi epatici. [Nicotinamide and liver lipids.] *Bol. Soc. ital. Biol. sper.*, 1954, **30**, 639-641. [Inst. Chim. Biol., Univ. Siena.]

Male rats weighing about 160 g. were injected with nicotinamide in an amount [not stated] sufficient to promote a demonstrable increase of diphosphopyridine nucleotide in the liver. They were killed at intervals of from 6 to 72 hr. later. In the liver, diphosphopyridine nucleotide increased and reached its peak value after 12 hr.; total fats and total and free cholesterol increased to a peak after 24 hr. Glycogen decreased and had not quite regained its initial value after 72 hr. All other values had returned to normal after 72 hr.—E. M. Hume.

3523

IACHELLO, I. Azione difasica del nicotinato sodico sul cuore isolato. [Diphasic action of sodium nicotinate on the isolated heart.] *Bol. Soc. ital. Biol. sper.*, 1954, **30**, 656-657. [Inst. Fisiol. Gen., Univ. Catania.]

The isolated heart of the common toad, *Bufo vulgaris*, was perfused with Ringer solution, suitably buffered, and with concentrations of Na nicotinate ranging from 10^{-1} to 10^{-10} . At concentrations of from 10^{-1} to 10^{-5} Na nicotinate had a negative inotropic and chronotropic action which disappeared on washing, but at concentrations below 10^{-5} there was a positive inotropic and chronotropic action which did not disappear on washing, and the heart showed great resistance to fatigue.—E. M. Hume.

3524

FITZPATRICK, F. K. (with PIETRYK, S. T.) **Nicotinamide in murine tuberculosis.** *Proc. Soc. Exp. Biol. Med.*, 1955, **88**, 54-56. [Dept. Virol., Sharp and Dohme Div., Merck and Co., West Point, Pa.]

The observation that nicotinamide had an inhibitory effect on mycobacterial infection in rodents (Absts. 1671, Vol. 16; 4325, Vol. 18) was further investigated. Mice were inoculated as described previously (*Amer. Rev. Tuberc.*, 1953, **68**, 451) with a dose calculated to be lethal to untreated mice in about 3 weeks. Drugs were given in the diet or by subcutaneous injection. Survival time was increased by nicotinamide in a daily dose of 25 mg. given orally, or of 10 mg. given subcutaneously. Initiation of the treatment a day or two before inoculation increased survival time, but when delayed till afterwards there was little effect. Seventeen compounds related to nicotinamide, even as nearly as nicotine acid, had no effect. Coenzyme I alone had no effect but it enhanced the effect of nicotinamide. Choline, methionine and ethanolamine, being substances containing methyl groups, were tested to see if they would counteract the effect of nicotinamide, but they did not do so. Nicotinamide did not enhance the effect of tuberculostatic drugs such as streptomycin. Speculation as to the mode of action of nicotinamide led to no conclusion.

E. M. Hume.

ANTONIANI, C., FEDERICO, L. and VALLE, T. Contributi alla conoscenza del contenuto vitaminico dei prodotti agrari e d'uso agrario.

6. Contenuto in vitamina PP degli ortaggi e delle frutta. [The vitamin content of produce and products used on the farm. 6. Vitamin PP content of vegetables and fruit.] *Ann. Sper. agrar.*, 1954, **8**, 919-927. [Staz. Sper. Freddo, Milan.] English summary.

For previous parts see Absts. 417, 597, Vol. 22; 1604, Vol. 23.

Nicotinamide was estimated by the method with CNBr in 25 genera and species of vegetables and 20 fruits. The Latin names of the vegetables are given. The values are tabulated for the dry and fresh tissue. In the dry material values in mg. per 100 g. ranged for vegetables from 1.05 for onions to 30.0 for tomatoes, and for fruits from 0.25 for Winesap apples to 17.75 for plums of the variety Florentia.—E. M. Hume.

3526

FEDERICO, L. and VALLE, T. Sul contenuto in vitamina PP dei formaggi italiani. [Vitamin PP content of Italian cheeses.] *Ann. Sper. agrar.*, 1954, **8**, 1489-1491. [Staz. Sper. Freddo, Milan.] English summary.

Nicotinamide was estimated by the same method as before (see preceding Abst.) in 10 Italian cheeses, some of them fast ripening and some slow. The values are tabulated with the moisture and lactic acid contents. The values for nicotinamide were low and ranged, in $\mu\text{g. per } 100 \text{ g. cheese}$, from 150 for Fontina to 785 for Robiola. The value for Bel Paese was 260, for Gorgonzola 320 and for Emmenthal 315. The value did not seem to be related to the rate of maturing.—E. M. Hume.

CHIANCONE, F. M., GINOUHLIAC, E., MAINARDI, L. and TENCONI, L. T. The elimination of some tryptophan metabolites after removal of endocrine glands. *Arch. Biochem. Biophys.*, 1955, **54**, 15-23. [Biol. Dept. Res. Labs., Lepetit S.p.A., Milan.]

The effect on tryptophan metabolism of removing the pituitary or adrenal glands was studied in rats given a purified diet with or without pyridoxine. In animals on the complete diet, removal of the

pituitary or adrenal glands reduced the excretion of kynurenine and diazotisable substances in response to a dose of tryptophan. After hypophysectomy, excretion of xanthurenic acid increased but after adrenalectomy it decreased, nicotinic acid increased and values for N¹-methyl-nicotinamide were unchanged. In the rats without pyridoxine, whether intact or not, the excretion of xanthurenic acid was always high, but adrenalectomy greatly reduced the excretion of kynurenine, which could be restored to normal by giving pyridoxine. A scheme for the reactions probably occurring in the breakdown of tryptophan is suggested.—A. M. Copping.

KOTAKE, Y. (Jr.) and NOGAMI, K. Research on xanthurenic acid. 9. On the conjugated compounds of xanthurenic acid formed in the body.

KOTAKE, Y. (JR.), INADA, T. and MATSUMURA, Y.
10. Research on the mechanism of xanthurenic-acid-initial hyperglycemia. *Proc. Japan Acad.*, 1954, **30**, 492-497; 626-631. [Dept. Biochem., Med. Coll., Wakayama.]

9. Rats were fed on a purified diet for 2 weeks, and were then given a subcutaneous injection of xanthurenic acid; urine was collected for the ensuing 24 hr., and xanthurenic acid in it was estimated by the method of Glazer *et al.* (*Abst.* 5328, Vol. 21) before and after hydrolysis with 3*N* *NCl*. The amount after hydrolysis was always somewhat greater than before. A filtrate of the urine obtained after standing as a mixture with alcohol to 50 per cent. was chromatographed on paper. The solutions used as developer were mixtures of *n*-butanol, acetic acid and water, and of methanol, *n*-butanol, benzene and water. With both developers 4 spots appeared. From examination of them it was concluded that there were 2 kinds of conjugated compounds of xanthurenic acid, one giving the diazo reaction and the other not. The former was easily hydrolysed with weak *HCl*, and was probably conjugated with glucuronic acid at the position of the OH radical at 4 in the quinoline ring. The OH radical at 8 in the quinoline ring was thought to play an important part in the diabetogenic action of xanthurenic acid. The substance not giving the diazo reaction was thought to be conjugated with the OH radical at 8, and was believed to be "a compound built up in the body as a sort of antitoxic substance".

10. Groups of from 5 to 10 rats were maintained on a purified diet for 2 weeks. The pituitary or adrenal glands were removed or the rats were injected with xanthurenic acid or adrenaline. The liver glycogen values were about half the normal in all except those injected with adrenaline, in which they were lower still. Ascorbic acid in the adrenal glands of those injected with adrenaline or xanthurenic acid was considerably less than in the normal rats. In rats from which the adrenal glands had been removed, the blood sugar value was maintained when adrenaline was injected but fell steadily for 2 hr. when xanthurenic acid was injected. When xanthurenic acid was injected after the pituitary gland had been removed, the blood sugar value fell, but not as low as after adrenalectomy. It was concluded that the pituitary and adrenal glands were essential in the production of the high blood sugar value which follows injection of xanthurenic acid in normal rats, and that the glycogen reserve in the liver was concerned also.

On the assumption that the sympathetic nervous system is somehow involved, adrenaline or xanthurenic acid was injected into normal rats with or without benzylimidazolidine, which inhibits the

action of adrenaline. With benzylimidazolidine, the rise in blood sugar, and fall in liver glycogen and adrenal ascorbic acid, normally induced by adrenaline, did not occur, but with xanthurenic acid the fall in liver glycogen and rise in blood sugar were not inhibited by imidazolidine; the fall in adrenal ascorbic acid did not occur.

TRONCI, L. T. Contributo allo studio dell'attività transaminasica di omogenati di fegato di ratto in rapporto alla piridossina. [*Contribution to the study of transaminase activity in rat liver homogenates in relation to pyridoxine.*] *Acta vitaminol.*, 1954, **8**, 275-276. [Lab. Direzione, Med. Centrale, Lepetit S.p.A., Milan.] French, English, German and Spanish summaries.

Groups of male rats 3 months old were fed on a stock diet or a diet deficient in vitamin *B₆*, the latter with no supplement or with, daily, 100 µg. pyridoxine hydrochloride, or 100 µg. riboflavin, or 125 µg. vitamin A suspended in gum arabic. The experiment lasted for from 170 to 235 days, after which homogenates of the liver were prepared, and the glutamic-alanine-transaminase was estimated in them, the amount of pyruvic acid liberated being the criterion. The activity in the liver of the rats given vitamin *B₆* was the same as of those given stock diet, but when riboflavin or vitamin A had been given the activity was reduced by 50 per cent., as in the rats given no supplement.

BATCHEN, J. M., CHEESMAN, E. M., COPPING, A. M. and TRÜSSLER, A. D. The effect of vitamin *B₆* on the growth and the blood picture of the rat. *Brit. J. Nutrition*, 1955, **9**, 49-57. [Dept. Physiol., Queen Elizabeth Coll. (Univ. London), Campden Hill Rd., W.8.]

Rats fed on a purified diet containing all other essential vitamins gave a growth response which paralleled the amount of pyridoxine given. Red blood cell counts rose in rats deficient in vitamin *B₆*; the cells were microcytic and hypochromic. Hb decreased only in severe deficiency. Mean corpuscular Hb and lymphocyte count were low in deficient rats.—A. Hepburn.

BEATON, J. R. and GOODWIN, M. E. Renal glutaminase activities in vitamin *B₆*-deficient rats. *J. Biol. Chem.*, 1955, **212**, 195-200. [Dept. Pub. Health Nutrit., Univ. Toronto, Canada.]

The phosphate-activated glutaminase of kidney tissue was measured by the method of White and Rolf (*Amer. J. Physiol.*, 1952, **169**, 174) in rats

N.A. and R., July 1955

having a purified diet with or without vitamin B₆. After 35 days' deprivation, renal glutaminase was less in rats given no vitamin B₆ than in pair-fed, non-deprived animals. When deoxypyridoxine was added to the diet signs of deficiency developed in about 20 days and renal glutaminase decreased. Addition of pyridoxal phosphate *in vitro* to kidney homogenates of deprived rats restored the glutaminase activity to normal. It had only a slight effect on kidney tissue from pair-fed, non-deprived rats.

In a test with 16 rats, deprivation of vitamin B₁ had no effect on renal glutaminase.

HOPE, D. B. **Pyridoxal phosphate as the coenzyme of the mammalian decarboxylase for L-cystine sulphinic and L-cysteic acids.** *Biochem. J.*, 1955, **59**, 497-500. [Dept. Pharmacol., Univ. Oxford.]

From experiments with liver extracts from the dog, rat, mouse, guinea-pig, rabbit and cat it seemed probable that a single enzyme was responsible for the decarboxylation of L-cysteic and L-cysteine sulphinic acids. The decarboxylase activity of the liver was higher in male than in female rats. In livers from rats deprived of vitamin B₆, decarboxylase activity decreased progressively as the time of deprivation increased. In the early stages of vitamin B₆ deficiency addition of pyridoxal-5-phosphate *in vitro* re-activated the liver decarboxylase, showing that pyridoxal phosphate was the coenzyme concerned. There was no re-activation with pyridoxal phosphate when liver extracts were taken from rats deprived of vitamin B₆ for 2 weeks or longer.—A. M. Copping.

3534

DIETRICH, L. S. and SHAPIRO, D. M. **Testosterone augmentation of deoxypyridoxine antagonism of various vitamin B₆-containing enzyme systems in tumor and host tissue.** *Cancer Res.*, 1955, **15**, 133-138. [Dept. Biochem., Coll. Phys. Surg., Columbia Univ., New York.]

The effect of testosterone in increasing the inhibition of certain enzyme systems by deoxypyridoxine was studied in C57 BL mice with mammary adenocarcinoma 755. Testosterone was given in sesame oil by intramuscular injection and deoxypyridoxine in saline solution by intraperitoneal injection. Testosterone alone did not affect the activity of glutamic-aspartic or glutamic-alanine transaminase, decarboxylase or cysteine desulphhydrase in the liver, kidneys, heart, lungs or tumour tissue. In combination with deoxypyridoxine, testosterone increased the inhibition of the transaminases and decarboxylase. Deoxypyridoxine had no effect on the desulphhydrase. The antagonistic effect of deoxypyridoxine on

liver transaminase could be reversed if pyridoxine was injected 30 min. before deoxypyridoxine with or without testosterone.—A. M. Copping.

3535

WOOTEN, E., NELSON, M. M., SIMPSON, M. E. and EVANS, H. M. **Effect of pyridoxine deficiency on the gonadotrophic content of the anterior pituitary in the rat.** *Endocrinology*, 1955, **56**, 59-66. [Inst. Exp. Biol., Univ. California, Berkeley.]

Anterior pituitary glands of from 8 to 12 normal or vitamin-B₆-deficient rats were ground in isotonic saline and injected into immature female rats or immature squabs [presumably pigeons] in saline suspension with 2 per cent. butanol. The follicle-stimulating activity of pituitary preparations from the deficient rats was 7 times that of preparations from the normal rats. The stimulation of interstitial cells and the mammatropic activity of the pituitary appeared to be little affected by vitamin B₆ deficiency. The change in follicle-stimulating activity was much greater than any effect hitherto ascribed to inanition.—A. M. Copping.

BIANCHI DONNASIBILLA, L. and CORTESI, M. **Studio dei poteri immunitari nella carenza piridossinica sperimentale da desossipiridossina e da dieta.** [Capacity for immunisation in experimental pyridoxine deficiency produced by deoxypyridoxine and by diet.] *Acta vitaminol.*, 1954, **8**, 269-274. [Clin. Pediat., Univ. Pavia.] French, English, German and Spanish summaries.

Fifty-six male rats weighing from 180 to 200 g. were maintained on a basal diet lacking only vitamin B₆. Two groups were given for 30 days 15 µg. pyridoxine daily, and one in addition received daily, half an hour earlier, 150 µg. deoxypyridoxine. Every third day all the rats were given a dose of *Salmonella typhi-murium* vaccine, and on the 15th, 20th and 30th day blood samples were taken. There was no difference in agglutinating titre between the groups.

Some of the rats were maintained for 55 days on the basal diet with daily addition of 4 µg. pyridoxine and of 40 µg. deoxypyridoxine given half an hour earlier. Blood samples were taken on the 15th, 30th and 55th day, and tested for complement and for capacity to haemolyse foreign red cells. Compared with that of "controls", the haemolytic capacity was increased slightly but the complement titre was unchanged.

The last experiment was repeated with deprivation of vitamin B₆ instead of administration of the antivitamin. The experiment lasted 5 months. The results were the same as when deficiency was created with the antivitamin.—E. M. Hume.

3537

BRUN, J., CAYRÉ, R. M. and VIALIER, J. Influence de la vitamine B₆ sur l'activité antituberculeuse de l'isoniazid. [Effect of vitamin B₆ on the antituberculosis activity of isoniazid.] *C.R. Soc. Biol.*, 1954, **148**, 1817-1818. [Inst. Pasteur.]

No diminution in the bacteriostatic action of isoniazid was demonstrated when pyridoxine was added *in vitro* to cultures of *Mycobacterium tuberculosis*. In experiments with guinea pigs infected with human tuberculosis the bacteriostatic effect of isoniazid *in vivo* was not affected by pyridoxine given simultaneously.—A. M. Copping.

ABDERHALDEN, R. Über eine antagonistische Beziehung zwischen Pyridoxin und der Pyrimi-

dinkomponente des Aneurins. [An antagonistic relationship between pyridoxine and the pyrimidine component of vitamin B₁.] *Ztschr. Vitamin-, Hormon- Fermentforsch.*, 1954, **6**, 295-296. [Basle.]

A preliminary note is given of the power of pyridoxine to counteract the toxic effects in rats of 2-methyl-4-amino-5-hydroxymethylpyrimidine or of its derivative 2-methyl-4-amino-5-bromomethylpyrimidine, especially with a certain diet called "D.K.". Injection of 1 mg. pyridoxine simultaneously with 10 mg. of the pyrimidine derivative protected a 90 g. rat given D.K. diet from the lethal effects of the pyrimidine. Further investigations are in progress to determine the mechanism of the antagonistic effect.

PANTOTHENIC ACID

3539

ZUNIN, C. and BORRONE, C. Embriopatie da carenza di acido pantotenico. Effetto della pantoitaurina, antivitamina dell'acido pantotenico. [Embryonic malformations from pantothenic acid deficiency. Effect of pantoitaurine, antivitamin for pantothenic acid.] *Acta vitaminol.*, 1954, **8**, 263-268. [Ist. Clin. Pediat. "G. Gaslini", Univ. Genoa.] French, English, German and Spanish summaries.

Female rats in 7 groups of from 4 to 12 were given a simplified basal diet and received daily 150 µg. Ca pantothenate. Amounts of pantoitaurine dibromoanilide ranging from 0.5 to 2.5 mg. daily were given for varying periods beginning just before and just after mating. All the young were born alive; they were immediately killed for examination. Abnormalities in the young occurred only when pantoitaurine was given from before, or from one day after, mating till parturition. The abnormalities included malformation of the brain, visible externally as a lump, with oedema and haemorrhages, particularly of the limbs. The changes resembled those described by others in pantothenic acid deprivation.

LATA, G. F. and ANDERSON, E. Effect of prolonged pantothenic acid deprivation upon cholesterol synthesis in the rat. *Arch. Biochem. Biophys.*, 1954, **53**, 518-520. [Dept. Biochem., Coll. Med., State Univ. Iowa, Iowa City.]

The synthesis *in vitro* of cholesterol from acetate marked with ¹⁴C was studied with liver slices from rats given a diet lacking in pantothenate, a complete diet with restricted intake or a complete,

unrestricted diet. The diets were instituted at maturity and given for from 4 to 5 months to secure severe depletion of pantothenic acid. The synthesis of cholesterol was more than doubled in liver from deprived rats, and the glycogen content also was high. It is suggested that in prolonged deprivation of pantothenate there might be interference with some pathways of acetate metabolism so that more acetate might be available for cholesterol formation.—A. M. Copping.

3541

MOOKERJEE, S. and SADHU, D. P. Cholesterol synthesis in pantothenic acid deficiency. *Indian J. Physiol. Allied Sci.*, 1954, **8**, 137-140. [Dept. Physiol., Bengal Vet. Coll., Calcutta 37.]

A purified diet was given to 18 weanling rats for 2 weeks with no vitamin supplement and then for 6 weeks with a complete supplement or one lacking pantothenic acid. Those without pantothenic acid showed retarded growth, and analysis of their tissues gave lower values for glycogen and cholesterol in the liver, and for cholesterol in the blood, kidneys, adrenal glands and intestine, than in rats receiving pantothenic acid.—A. M. Copping.

3542

HURLEY, L. S. and MACKENZIE, J. B. Adrenal function in the pantothenic acid-deficient rat. Liver glycogen, blood glucose, adrenal cholesterol and adrenal ascorbic acid levels. *J. Nutrition*, 1954, **54**, 403-415. [Div. Chem. Embryol., Dept. Paediat., Sch. Med., Univ. Colorado, Denver.]

Weanling rats were maintained on purified diets with or without pantothenic acid for 6 weeks, and

N.A. and R., July 1955

were then killed without further treatment or after fasting for 24 hr. at atmospheric pressure or at a reduced oxygen tension corresponding to 20,000 ft. altitude. Blood sugar, liver glycogen, and the weight, ascorbic acid content and cholesterol content of the adrenal glands were measured. Great seasonal variations were found in the ascorbic acid and cholesterol content of the adrenal glands in both normal and pantothenic-acid-deficient animals, but the liver glycogen and blood sugar values showed a fairly constant pattern in the different groups. Rats deprived of pantothenic acid had lower values for liver glycogen, blood sugar and adrenal cholesterol, and higher values for adrenal weight and ascorbic acid content than comparable normal animals. After exposure to low oxygen tension normal, fasting rats showed a great increase in liver glycogen and blood sugar in comparison with rats kept at normal oxygen tension. The increase in glycogen and blood sugar was not found in pantothenic-acid-deficient rats in a state of anoxia. All animals showed a significant decrease in adrenal cholesterol in a state of anoxia.

It is suggested that in normal animals subjected to the stress of anoxia cholesterol is used in the synthesis of adrenal steroids with coenzyme A as a necessary component of the system, but that in pantothenic-acid-deficient animals the synthesis of cortical steroids is begun but is blocked by lack of coenzyme A at some intermediate stage, so that glyconeogenesis is not induced. The hypothesis is discussed with reference to the apparently conflicting findings of different observers on the effect of pantothenic acid deprivation on adrenal function.—A. M. Copping.

3543

DEB, C., BANERJEE, S. and MUKHERJEE, A. K. Adrenal-cortical activity in pantothenic acid deficient rats. *Indian J. Med. Res.*, 1954, 42, 589-597. [Dept. Physiol., Presidency Coll., Calcutta.]

Female rats of 100 to 150 g. weight were given a purified diet with and without pantothenic acid. Those having 250 μ g. pantothenic acid daily were pair-fed with deprived animals. The experiment continued for 6 months, during which the deprived rats did not lose weight, though alopecia and rusty staining of fur and whiskers were present by the end of the period. Acetylation of injected *p*-aminobenzoic acid was found to be defective in the deprived rats, and the excretion of ketosteroids was significantly decreased, though that of sodium and potassium changed very little. Blood glucose values were low in deprived rats and red cell counts were raised, but reticulocyte counts and Hb values showed no significant difference between deprived rats and pair-fed controls. Total white cell and

polymorphonuclear leucocyte counts were low in deprived rats; cholesterol and ascorbic acid content of adrenals and glycogen content of liver were also low. The findings are discussed and considered to show that hypofunction of the adrenal cortex is an essential lesion in rats deprived of pantothenic acid.—A. M. Copping.

3544

ANGELICO, R. and QUINTILIANI, M. Azione dell'acido pantotenico sul contenuto in glicogeno epatico di ratti surrenectomizzati. [Effect of pantothenic acid on the liver glycogen content in adrenalectomised rats.] *Rend. Ist. Super. Sanità, Rome*, 1954, 17, 13-18. French, English and German summaries.

Rats weighing from 65 to 70 g. were maintained for 32 days on a diet without pantothenic acid, containing 18 per cent. casein. The adrenal glands were removed and the rats were kept for 4 days on the same diet with a solution of 1 per cent. NaCl to drink. Of 13 rats thus treated, 7 were given subcutaneously 4 doses of 2 mg. Ca pantothenate at intervals of 2 hr. All were killed fasting, 2 hr. after the time of the last injection. For those given and not given pantothenate, respectively, the value for glycogen in the liver was 22.3 and 23.8 mg. per 100 g. fresh tissue, and for blood sugar 62 and 60 mg. per 100 ml.

Two further groups of rats were treated in the same way with addition of cortisone acetate in a total dose of 1 mg., administered in 4 parts at the same time as the 4 doses of pantothenate. The blood sugar values were raised to the same extent, to 98 and 99 mg. per 100 ml., but the liver glycogen value was for those given pantothenate only 45.9 mg. per 100 g. fresh tissue and for those not given it, 168.6.—E. M. Hume.

3545

ANGELICO, R. and QUINTILIANI, M. Influenza del tasso proteico della dieta sull'azione dell'acido pantotenico sul contenuto in glicogeno del fegato di ratti surrenectomizzati. [Effect of the protein content of the diet on the action of pantothenic acid on the liver glycogen content in adrenalectomised rats.] *Bol. Soc. ital. Biol. sper.*, 1954, 30, 680-682. [Lab. Biol., Ist. Super. Sanità, Rome.]

In previous experiments (see preceding Abst.) the diet used, devoid of pantothenic acid, contained 18 per cent. of casein; in the present experiment the amount of sucrose was reduced and the percentage of casein was increased to 58. The adrenal glands were removed from 42 rats and all were given cortisone; 10 were maintained on the diet without pantothenic acid, and Ca pantothenate was given simultaneously with cortisone to 6 of them. Thirty-two were maintained on the diet

with pantothenic acid and Ca pantothenate was given simultaneously with cortisone to 16 of them. The glycogen content of the liver, in mg. per 100 g. fresh tissue, was for the adrenalectomised rats deprived of pantothenic acid and given cortisone 219.5, for the same with Ca pantothenate given simultaneously 263.5, for the adrenalectomised rats not deprived of pantothenic acid and given cortisone 403.8, and for the same given Ca pantothenate simultaneously 407.4. The low values previously obtained for glycogen in the liver of adrenalectomised rats deprived of pantothenic acid and given cortisone and Ca pantothenate simultaneously, in comparison with rats treated in the same way but not given Ca pantothenate simultaneously, were thus not obtained when the diet contained 58 per cent. of casein as against 18 per cent.—E. M. Hume.

3546

ANGELICO, R. and QUINTILIANI, M. Studi sulla gluconeogenesi nel ratto floricizzato, carente di acido pantothenico. 2. Esperienze su animali carenti, intatti e surrenectomizzati. [Glyconeogenesis in phloridzinised rats deprived of pantothenic acid. 2. Experiments on deprived animals, intact and adrenalectomised.] Cortisone e acidopantothenico nella gluconeogenesi del ratto surrenectomizzato. [Cortisone and pantothenic acid in the gluconeogenesis of the adrenalectomized rat.] *Rend. Ist. Super. Sanità, Rome*, 1954, 17, 91-98; 99-105. French, English and German summaries.

Groups of from 8 to 17 rats weighing from 55 to 60 g. were maintained for from 5 to 8 weeks on a diet described elsewhere (*ibid.*, in the press) with or without pantothenic acid. They were treated with phloridzin after fasting for 24 or 48 hr. The adrenal glands were removed from a deprived and a non-deprived group, treated with phloridzin, after 24 hours' fast. In the intact rats given phloridzin, the amounts of glucose and N in the urine were greater in the deprived than in the non-deprived, but ketone bodies were less. The differences tended to disappear with the 48-hr. fast. After adrenalectomy all the differences were much less, and did not differ significantly between deprived and non-deprived animals. Histological examination of the adrenal glands showed the necrotic, haemorrhagic lesions characteristic of pantothenic acid deficiency. It is concluded that no damage to the gluconeogenesis function of the adrenal cortex could be demonstrated in pantothenic acid deficiency.

Six groups of from 6 to 24 male rats weighing from 65 to 70 g. were maintained on a complete, purified diet containing 18 per cent. casein with or without Ca pantothenate. After 32 days for the deprived, and from 35 to 50 days for the non-

deprived, the adrenal glands were removed and a solution of 1 per cent. NaCl was given for drinking for 4 days. Food and water were then withdrawn and cortisone was given to 2 deprived and 2 non-deprived groups, one each of which received extra Ca pantothenate. The cortisone and pantothenate were given simultaneously in 4 spaced doses at intervals of 2 hr. The animals were then all killed and glycogen in the liver was estimated. In the rats subjected to adrenalectomy, whether deprived of pantothenic acid or not, the respective values for glycogen in mg. per 100 g. liver were 23.8 and 36.8, and for blood sugar in mg. per 100 ml. 60 and 70. When cortisone was given to the adrenalectomised rats the values were higher, being for deprived and non-deprived, respectively, glycogen 168.6 and 385.3, and blood sugar 92 and 99. With simultaneous administration of extra Ca pantothenate with the cortisone, the blood sugar values and the liver glycogen values did not differ greatly from those in the corresponding 2 groups not given Ca pantothenate simultaneously, except the liver glycogen value for deprived rats, which was very low indeed, only 45.9. The significance of this result is discussed.—E. M. Hume.

HAZELWOOD, R. L., BENNETT, L. L. and NELSON, M. M. Reduction of the nitrogen-retaining effect of growth hormone in normal and adrenalectomized pantothenic acid-deficient rats. *Endocrinology*, 1955, 56, 197-203. [Dept. Physiol., Inst. Exp. Biol., Univ. California, Berkeley.]

Male rats aged 30 days were given for 57 days a purified diet with or without pantothenic acid. They were then kept in individual metabolism cages and N excretion in the urine was measured for 6 days before some animals received injections of growth hormone. In rats deprived of pantothenic acid and showing typical signs of deficiency, injection of growth hormone caused a decrease in N excretion of 33 mg. from an original daily output of 256 mg. More than twice this decrease occurred in pair-fed rats given pantothenic acid. Similar effects were obtained in a further experiment, and a higher dose of hormone did not increase N retention unless pantothenic acid was given. In a third experiment removal of the adrenal glands had no effect on the resistance to growth hormone of rats deprived of pantothenic acid.—A. M. Copping.

3548

GIUNCHI, G., FIDANZA, A., SCURO, L. A. and SORICE, F. The influence of some antibiotics on the growth and the production of antibodies in rats fed a pantothenic acid deficient diet. *Exp. Med. Surg.*, 1954, 12, 430-433. [Inst.

N.A. and B., July 1955

Gen. Physiol., Univ. Rome.] French and German summaries.

Rats which received a purified diet lacking pantothenic acid from 4 weeks of age showed failure of growth and decreased ability to form circulating antibodies in response to immunisation with *Salmonella typhi* or *Brucella melitensis*. Both growth and antibody production were improved when 0.05 per cent. of chloromycetin, aureomycin, penicillin or dihydrostreptomycin was added to the deficient diet.—A. M. Copping.

3549

ASENJO, C. F. and MUÑIZ, A. I. **Pantothenic acid content of tropical foods.** *Food Res.*, 1955, **20**, 47–54. [Dept. Biochem. Nutrit., Sch. Med., Univ. Puerto Rico, San Juan.]

The results of microbiological estimation of pantothenic acid with *Lactobacillus arabinosus* are tabulated for over 100 Puerto Rico foods, mainly cereals, fruits and vegetables but including a few animal foods, in $\mu\text{g.}$ per 100 g. edible portion, means and ranges. Spanish names of foods and Latin names of plants are given. High values, between 1000 and 2000, were found for avocado pear, passion fruit, dried black beans (*Dolichos lablab*, L.), wild pepper (*Capsicum frutescens*, L.), breadfruit seed (*Artocarpus communis*, Forst) and cashew nut (*Anacardium occidentale*, L.); the seed of stinking weed (*Ditremexa occidentalis*, L.) had a value of 2655. Food yeast (*Torula utilis*) had a value of 9000 and brewer's yeast of nearly 16,000. The value for egg yolk was over 3000 and for egg white under 300.—W. M. Deans.

BIOTIN

3550

LOCHSTEIN, H. C. **The presence of bound biotin in purified preparations of oxalacetic carboxylase.** *J. Biol. Chem.*, 1955, **212**, 217–222. [Dept. Bacteriol. Immunol., Univ. Minnesota, Minneapolis.]

Biotin was estimated with *Saccharomyces cerevisiae* and *Lactobacillus arabinosus* in samples of oxalacetic carboxylase before and after acid hydrolysis. With *S. cerevisiae* the presence of bound biotin was demonstrated in many of the enzyme preparations. There appeared to be a relationship between the amount of bound biotin present and the purity of the preparation. *L. arabinosus* was not satisfactory for estimating biotin in the enzyme preparations, being less sensitive to low concentrations than *S. cerevisiae*. The specificity of the response of *S. cerevisiae* was tested with the antagonist homobiotin. It is suggested that the reported absence of bound biotin from oxalacetic carboxylase may have been based on the use of an unsuitable test organism.

MOAT, A. G. and EMMONS, E. K. **The amino acid nutrition of yeast in relationship to biotin deficiency.** *J. Bacteriol.*, 1954, **68**, 687–690. [Dept. Microbiol., Hahnemann Med. Coll., Philadelphia, Pa.]

The effect of amino-acids given singly or together on the growth of *Saccharomyces cerevisiae*, Fleischmann strain 139, was studied in a medium containing suboptimum amounts of biotin. Only aspartic acid was capable of producing a specific stimulation of growth in these conditions; other amino-acids had no effect when added individually to the medium, with or without aspartic acid.

Aspartic acid, tryptophan, arginine, leucine and methionine together were necessary to produce growth equivalent to that obtained with a complete amino-acid mixture. If aspartic acid was omitted tyrosine, isoleucine, glycine, valine, phenylalanine, alanine, histidine and glutamic acid were important; with aspartic acid present they seemed not to be essential.—A. M. Copping.

GOTHOSKAR, S. S., REGE, D. V. and SREENIVASAN, A. **Biotin metabolism in micro-organisms. 6. Nucleic-acid synthesis.** *Indian J. Med. Res.*, 1954, **42**, 599–604. [Dept. Chem. Technol., Univ. Bombay.]

Synthesis of pentosenucleic acids and deoxy-pentosenucleic acids by *Lactobacillus arabinosus*, *L. casei* and *Bacillus subtilis* was reduced by addition of biotin to the basal media. Aspartate, oleate and inositol, which can replace biotin as growth substances for certain micro-organisms, had a similar depressing effect on nucleic acid synthesis.

A. M. Copping.

RAVEL, J. M. and SHIVE, W. **A study of biotin sulfone inhibition of *Lactobacillus arabinosus*.** *Arch. Biochem. Biophys.*, 1955, **54**, 341–348. [Biochem. Inst., Univ. Texas, Austin.]

Lactobacillus arabinosus could grow in a synthetic medium containing aspartic acid and a source of oleic acid but no exogenous source of biotin. Addition of biotin sulphone to the medium inhibited growth. The inhibition could be overcome by threonine, lysine and uracil and partly also by an increase in the aspartic acid concentration.

MONTE, I. W., NELSON, M. M. and EVANS, H. M. Abnormalities of the urinary system of rat embryos resulting from maternal pteroylglutamic acid deficiency. *Anat. Rec.*, 1954, 120, 119-129. [Dept. Anat., Univ. California, Berkeley.]

Multiple congenital abnormalities were found in young from rats deprived of pteroylglutamic acid from the 11th day of gestation (Abst. 1637, Vol. 23). A detailed study of the urinary system was made in embryos of foetal age 12 to 21 days from mothers deprived of pteroylglutamic acid at 11 days after positive mating. The first sign of abnormality was retardation of development of the ureters in 15-day embryos. The development of the kidney was retarded in 17-day embryos, and that of the urethra at 18 days. At 21 days two-thirds of the embryos from deprived rats showed severe renal and uterine hypoplasia and one-third had moderate hypoplasia, hydronephrosis and occasionally hydro-ureter. The changes in these embryos are discussed with reference to non-obstructive hydronephrosis and to the formation of posterior urethral valves in man.—A. M. Copping.

TENTORI, L. and VIVALDI, G. La vitamina B₁₂ ed il fattore intrinseco antipernicioso nella anemia macrocitica sperimentale del ratto carente di acido folico. [Vitamin B₁₂ and intrinsic factor in the experimental macrocytic anaemia of rats deprived of folic acid.] *Rend. Ist. Super. Sanità, Rome*, 1954, 17, 115-122. French, English and German summaries.

Folic acid deficiency was produced in 56 rats fed on the diet described by Black *et al.* (Title 2390, Vol. 11), with the addition of 2 per cent. succinylsulphathiazole. They were then divided into 7 groups and were given every 3 days 0.05 or 0.5 µg. vitamin B₁₂ by intramuscular injection, or 0.75 or 15 µg. vitamin B₁₂ by mouth, or 2 ml. normal human gastric juice, or 0.75 µg. vitamin B₁₂ with 2 ml. gastric juice; the seventh group received weekly 250 µg. folic acid by intramuscular injection. The response of the blood picture was studied; results are shown in graphs and in a table.

The smaller dose of vitamin B₁₂ given parenterally had no significant effect, nor had 0.75 µg. vitamin B₁₂ given by mouth, even with gastric juice. The doses of 0.5 µg. given by intramuscular injection and 15 µg. given by mouth produced a good response. It is concluded that to secure a response in the anaemia produced in rats by folic acid deficiency, relatively larger doses of vitamin B₁₂ are required on a bodyweight basis than in

pernicious anaemia in man, and that the intrinsic factor in human gastric juice does not increase the efficacy of vitamin B₁₂ given to rats by mouth.

DOCTOR, V. M. and TRUNNELL, J. B. *In vivo* and *in vitro* conversion of folic acid to citrovorum factor by rat. *Proc. Soc. Exp. Biol. Med.*, 1954, 87, 498-500. [Sect. Exp. Med., Univ. Texas, Houston.]

Adult male rats, given a normal diet and 100 µg. folic acid daily alone or with addition of 15 mg. L-cysteine or DL-homocysteine, were kept in metabolism cages and citrovorum factor in their urine was estimated with *Leuconostoc citrovorum*. Folic acid caused a sixfold increase in the urinary excretion of citrovorum factor and the increase was enhanced by L-cysteine or DL-homocysteine. If L-cysteine was given without folic acid there was some increase in excretion of citrovorum factor, but DL-homocysteine without folic acid had no effect.

Homogenates of rat liver showed increased ability to convert folic acid to citrovorum factor in presence of formate, serine or homocysteine; the effect of homocysteine was enhanced by serine but reduced by formate.—A. M. Copping.

FATTERPAKER, P., MARFATIA, U. and SREENIVASAN, A. Role of folic acid and vitamin B₁₂ in trans-methylations. 1. Formation of creatine *in vitro* and *in vivo*. *Indian J. Med. Res.*, 1955, 43, 43-50. [Dept. Chem. Technol., Univ. Bombay.]

Adult Swiss mice were given, for from 2 to 3 weeks, a purified diet lacking in folic acid or vitamin B₁₂ or both. Creatinine was measured in the urine before the mice were killed and afterwards in the skeletal muscle. There was a considerable decrease in creatine excretion and storage with deficiency of either vitamin or of both, and little difference between the values for the 3

N.A. and R., July 1955

groups. Liver slices from animals deprived of either nutrient showed a low rate of synthesis of creatine *in vitro*; with slices from mice lacking both nutrients the rate of synthesis was lowest.

FATTERPAKER, P., MARFATIA, U. and SREENIVASAN, A. Observations on the relationship between pteroylglutamic acid and nicotinamide metabolism. *Biochem. J.*, 1955, **59**, 470-475. [Dept. Chem. Technol., Univ. Bombay.]

Pteroylglutamic acid deficiency was induced in young rats with a purified diet containing iodinated casein and, in older animals given a stock diet, by injection of aminopterin. Nicotinamide was added as 0.5 per cent. of the purified diet or given by mouth in a dose of 25 mg. daily. The animals were killed after from 32 to 38 days, or after 12 days in the groups given aminopterin. In all the deficient rats there was an increase in the weight of liver, kidney and adrenal glands and the increases were greater when excess of nicotinamide was given. The neutral fat of the liver increased and the choline and methionine content decreased. There was a decrease in choline oxidase and a slight decrease in xanthine oxidase activity in the liver. The adrenaline content of the adrenal glands increased. All these effects of nicotinamide toxicity combined with pteroylglutamic acid deficiency were overcome by large doses of 100 μ g. pteroylglutamic acid daily. Addition of 0.5 per cent. choline to the diet also overcame the toxic effects of nicotinamide, which were closely related to methylation reactions.

In simple deprivation of pteroylglutamic acid there was no change in the content of pantothenic acid and coenzyme A in the liver, but excess of nicotinamide produced low values for both. The effect was counteracted by choline added to the diet.—A. M. Copping.

3560

NICHOL, C. A., ANTON, A. H. and ZAKRZEWSKI, S. F. A labile precursor of citrovorum factor. *Science*, 1955, **121**, 275-279. [Dept. Pharmacol., Sch. Med., Yale Univ., New Haven, Conn.]

As a result of studies designed to investigate the reaction of a cell or an organism to folic acid antagonists, a tentative scheme is suggested for interrelationships of compounds related to folic acid. A labile precursor of citrovorum factor was an essential component in such a scheme. A compound formed during anaerobic incubation of folic acid with cells of *Streptococcus faecalis* was labile to heat and oxidation, and was converted in anaerobic conditions to the stable citrovorum factor. The labile compound appeared to be a tetrahydro-derivative of folic acid. The existence of the

labile precursor is discussed with reference to enzymic and non-enzymic degradation of essential metabolites in the folic acid system.

GOLDIN, A., VENDITTI, J. M., HUMPHREYS, S. R., DENNIS, D., MANTEL, N. and GREENHOUSE, S. W. Factors influencing the specificity of action of an antileukemic agent (aminopterin). Multiple treatment schedules plus delayed administration of citrovorum factor. *Cancer Res.*, 1955, **15**, 57-61. [Lab. Chem. Pharmacol., Nat. Cancer Inst., Bethesda, Md.]

The effect of one or more doses of aminopterin, with or without citrovorum factor given 12 hr. later, was examined in mice inoculated with leucæmia tumour cells. A total of from 0.78 to 214 mg. aminopterin per kg. bodyweight was given with a protective dose of 400 mg. citrovorum factor. Citrovorum factor given after aminopterin appeared to reverse the damage done by aminopterin in the host but not in the tumour. Use of 2 or 3 doses of aminopterin at intervals of 2 days, or addition of citrovorum factor, increased the antileucæmic effect of aminopterin. Multiple doses of aminopterin with citrovorum factor were the most effective treatment.—A. M. Copping.

3563

CHUBE, L. G. and LAURSEN, A. L. Further observations on the effect of aminopterin, A-methopterin and citrovorum factor on the growth of transplantable avian lymphoid tumours. *Brit. J. Pharmacol. Chemotherap.*, 1954, **9**, 419-422. [Poultry Res. Stat., Animal Health Trust, Houghton, Hunts.]

Injected aminopterin was toxic for chicks, so that its effect on tumour growth could not be determined. Aminopterin in the diet was toxic only occasionally and in most birds it decreased the number of tumours which developed and prolonged survival time. Some inhibition of tumour growth was shown by A-methopterin, which was less toxic when injected intraperitoneally than

aminopterin. It inhibited tumour growth when given in the diet. The toxic effects of injected A-methopterin and aminopterin were counteracted by the injection of citrovorum factor. The use of citrovorum factor prevented the tumour-inhibiting action of the two folic acid antagonists.

VITAMIN B₁₂

3565

CREMA, A. Sul dosaggio microbiologico della vitamina B₁₂ nei materiali biologici. [Microbiological estimation of vitamin B₁₂ in biological materials.] *Arch. Sci. biol., Bologna*, 1955, **39**, 80-92. [Ist. Farmacol., Univ. Pavia.]

Strains of *Bacterium coli*, 313/3 and 213, requiring vitamin B₁₂ and methionine were found to be the most satisfactory organisms for estimating vitamin B₁₂ by the cup-plate method or by measuring the diameter of colonies. Methionine interfered with the method only when its concentration was relatively high. Vitamin B₁₂ was present in liver in a state in which it was not available to the organisms, and the liver was capable of rendering non-available free vitamin B₁₂ added to it *in vitro*. In experiments with guinea pig's liver, boiling on a water-bath set the vitamin free; more was liberated in 120 min. than in 80.—E. M. Hume.

3566

YRAGUI, M. M., WEEKS, O. B. and WIESE, A. C. Influence of the amino acids of synthetic media upon the response of *Lactobacillus leichmannii* to vitamin B₁₂. *J. Bacteriol.*, 1955, **69**, 20-27. [Dept. Bacteriol., Idaho Agric. Exp. Stat., Moscow.]

An exhaustive investigation was made of the amino-acids required in synthetic media by 2 strains of *Lactobacillus leichmannii*. The amino-acid requirement was judged by the response to vitamin B₁₂. Growth could be obtained in media containing 12 or 14 amino-acids but the maximum effect was obtained with a mixture of 22 amino-acids and the same basal medium. Strain 4797 required L(-)proline and DL-threonine but not DL-lysine or β-alanine. Strain 7830 required DL-lysine but not L(-)proline or DL-threonine. Solutions of amino-acids were more effective for the first week after preparation than after storage for several weeks.

Serial culture of the organisms in the complete synthetic medium produced adapted populations which no longer required vitamin B₁₂. Adaptation

did not occur in a medium containing an acid hydrolysate of soya bean or if ascorbic acid was omitted from the medium. Vitamin B₁₂ could be partly replaced in the synthetic media by thymidine or deoxyribonucleic acid.—A. M. Copping.

THUILLIER, Y. and PERAULT, R. Facteur intrinsèque. Essai d'une méthode de titrage microbiologique dans les extraits pyloriques de porc. [Intrinsic factor. A method for microbiological estimation in pylorus extracts of the pig.] *Bull. Soc. Chim. biol.*, 1954, **36**, 1439-1446. [Serv. Sci. Lab. Albert Rolland.]

Intrinsic factor activity was estimated in dried pylorus and in purified extracts by estimating the amount of vitamin B₁₂ fixed by a given weight of tissue, and the amount of the vitamin which could be set free by autoclaving the mixture. Vitamin B₁₂ was estimated with *Bacterium coli* 113/3 on an agar plate. The vitamin-B₁₂-binding capacity was tested at pH 6.3 at 37° C. in a phosphate buffer. No intrinsic factor activity was demonstrated in an extract of pig's gastric mucosa; a sample of whole-stomach powder had slight activity. Among the tissues examined pyloric antrum contained most. The results obtained by the method were in agreement with clinical observation.

3568

THUILLIER, Y. and PERAULT, R. Thermolabilité du facteur intrinsèque. [Thermolability of the intrinsic factor.] *C.R. Soc. Biol.*, 1954, **148**, 1553-1555. [Serv. Sci. Lab. Albert Rolland.]

The destruction by heat of binding capacity for vitamin B₁₂ was studied in crude and purified preparations of intrinsic factor from hog's stomach. Crude preparations retained slight activity even after heating to 100° or 120° C., but purified preparations, which lost relatively little activity on incubation at 50° or 70° C., were completely inactivated at 100° C. The thermolability of the intrinsic factor is considered to confirm that it is protein in nature.—A. M. Copping.

3569

ROSENBLUM, C., WOODBURY, D. T., GILFILLAN, E. W. and EMERSON, G. A. **Effect of intrinsic factor concentrate upon utilization of orally administered vitamin B₁₂ by rats.** *Proc. Soc. Exp. Biol. Med.*, 1954, **87**, 268-273. [Res. Labs., Merck and Co., Inc., Rahway, N.J.]

Rats receiving a purified basal diet with soya bean protein were given by mouth vitamin B₁₂ containing ⁶⁰Co with and without a highly active preparation of intrinsic factor from pig's stomach. A second group of rats received the same diet with vitamin B₁₂ and had in addition the dose of radioactive vitamin B₁₂ with or without intrinsic factor. The animals were kept in metabolism cages and the excretion of vitamin B₁₂ in the urine and faeces and the retention in liver and kidney were used to assess the absorption of the vitamin. It seemed that intrinsic factor reduced the ability of the rat to absorb and utilise vitamin B₁₂. The inhibitory effect of intrinsic factor was shown whether vitamin B₁₂ was present in the basal diet or not, and even after injection of a massive dose of vitamin B₁₂.—A. M. Copping.

3570

CRESSERI, A. Osservazioni sulle caratteristiche biologiche e chimiche di frazioni mucoproteiche ottenute dalla mucosa gastrica di maiale. [Biological and chemical properties of mucoprotein fractions from the gastric mucosa of the pig.] *Bol. Soc. ital. Biol. sper.*, 1954, **30**, 718-720. [Lab. Ricerche Biol., Ist. "Carlo Erba", Milan.]

The investigation was made by electrophoresis on paper, but isolation was not achieved by this means of a substance specially endowed with the property of binding vitamin B₁₂. A method of purification with different concentrations of phenol and ethanol is suggested.—E. M. Hume.

3571

FORD, J. E., HOLDSWORTH, E. S. and KON, S. K. **The biosynthesis of vitamin B₁₂-like compounds.** *Biochem. J.*, 1955, **59**, 86-93. [Nat. Inst. Res. Dairying, Univ. Reading.]

A mutant of *Bacterium coli* was able to synthesise vitamin B₁₂ and related compounds if the non-nucleotide cobalt complex, factor B, was present with an appropriate nucleotide. With compounds related to adenine or to 5:6-dimethylbenzimidazole, "unnatural" analogues of vitamin B₁₂ were obtained. Some of the new compounds promoted the growth of *Ochromonas malhamensis*, which had been thought to respond specifically to cyanocobalamin. Biosynthesis of vitamin B₁₂ analogues was obtained also with wild strains of *Bact. coli* and with *Aerobacter aerogenes*.—A. M. Copping.

Vol. 25, No. 3

3572

BERNHAEUER, K., FRIEDRICH, W., BECHER, E., DELLWEG, H. and GROSS, G. Über die Vitamine der B₁₂-Gruppe. [The vitamin B₁₂ group.] *Angewandte Chem.*, 1954, **66**, 776-780. [Biochem. Forsch.-Lab., Aschaffenburg Zellestoffwerke A.G., Stockstadt (Main).]

A review is given of the authors' work (ibid., 1953, **65**, 627) in preparing a crude concentrate of B₁₂ vitamins from sewage sludge by heating, filtering, adsorption and elution. The vitamins were purified by extraction with phenol, transfer to water and precipitation with *p*-chlorophenol on to kieselguhr. The individual B₁₂ vitamins were separated by column chromatography and crystallisation. The use of halogen-substituted phenols for the purpose is described. Factors I, II, III, IV and V were isolated in this way. The vitamin B₁₂ activity in the dry matter of different sludges ranged from 1 to 30 mg. per kg. as tested with *Bacterium coli* mutants, and from 1 to 15 as tested with *Lactobacillus leichmannii*. The prevailing forms of the vitamin were I, II and III. The chemical constitution of the forms of vitamin B₁₂ is discussed and a table is given of their properties with a suggested rational system of nomenclature based on chemical constitution as far as it is known. Tests for biosynthesis of B₁₂ vitamins from a great number of precursors is reported.—E. M. Hume.

BROWN, F. B., CAIN, J. C., GANT, D. E., PARKER, L. F. J. and SMITH, E. L. **The vitamin B₁₂ group. Presence of 2-methyl purines in factors A and H and isolation of new factors.** *Biochem. J.*, 1955, **59**, 82-86. [Glaxo Laboratories, Ltd., Greenford, Middlesex.]

Active substances extracted from pig and calf manure with boiling 50 per cent. ethanol were purified by partition chromatography. Some were identified as factors A, B and C (Title 2039, Vol. 22) and ψ -vitamin B₁₂ (Abst. 2035, Vol. 22) and others were called factors D, E, F, G, H and I. On deamination, factor A yielded factor H, which on mild hydrolysis gave 2-methylhypoxanthine. Deamination of ψ -vitamin B₁₂ gave rise to factor G, which contained hypoxanthine. On removal of nucleotides with warm concentrated HCl, ψ -vitamin B₁₂ and factors A, G and H all yielded factor B, which is the main cobalt-containing part of the vitamin B₁₂ molecule.—A. M. Copping.

3574

FANTES, K. H. and O'CALLAGHAN, C. H. **The effect of o-phenylenediamine on the biosynthesis of vitamin B₁₂: a new vitamin B₁₂ analogue.** *Biochem. J.*, 1955, **59**, 79-82. [Glaxo Laboratories, Ltd., Sefton Park, Stoke Poges, Bucks.]

The increase of vitamin B₁₂ activity produced in the course of fermentation by *Streptomyces griseus* in presence of *o*-phenylenediamine, reported by Dulaney and Williams (*Mycologia*, 1953, 3, 345), was found to depend on the formation of a new analogue of vitamin B₁₂. The biosynthesis of true vitamin B₁₂ was competitively inhibited by *o*-phenylenediamine. The biosynthesis of the analogue in presence of *o*-phenylenediamine was competitively inhibited by 1:2-diamino-4:5-dimethylbenzene. The analogue was crystallised as red needles, and its absorption spectrum was almost identical with that of vitamin B₁₂. Benzimidazole was a product of hydrolysis of the analogue, which was almost certainly identical with the substance reported by Ford *et al.* (Title 2016, Vol. 25). The material was clinically active in tests on 3 patients with pernicious anaemia.—A. M. Copping.

GREGORY, M. E. and HOLDSWORTH, E. S. **The occurrence of a cyanocobalamin-binding protein in milk and the isolation of a cyanocobalamin-protein complex from sow's milk.**

Some properties of the cyanocobalamin-protein complex from sow's milk, and the mode of linkage of cyanocobalamin with protein. *Biochem. J.*, 1955, 59, 329-334; 335-340. [Nat. Inst. Res. Dairying, Univ. Reading.]

Protein capable of binding cyanocobalamin was demonstrated in milk from cow, goat, pig, rat and woman by an ultrafiltration method. Sow's milk had the highest binding capacity, and a pure cyanocobalamin-protein complex was isolated by electrophoresis from sow's milk whey. Electrophoresis of whey proteins of milk from other species indicated that the chief proteins did not combine with cyanocobalamin and that the pattern of the cyanocobalamin-protein complex was similar in all the samples examined.

The cyanocobalamin-protein complex from sow's milk whey in aqueous solution showed absorption maxima at 278, 362, 410, 520 and 555 m μ . Chemical analysis gave 16.1 per cent. N, 7 per cent. carbohydrate and 9 per cent. hexosamine. Sixteen amino-acids were detected by chromatographic analysis of the protein; the amount of tyrosine was higher than that in many proteins. From the absorption curve and from microbiological tests the complex was found to contain 23 μ g. cyanocobalamin per mg. On the assumption that one molecule of protein combines with one molecule of cyanocobalamin a molecular weight of 55,000 was

deduced for the protein. The mode of linkage was investigated by studying the effect of specific group inhibitors. It seemed that a phenolic or an amino-group in the protein might be the point of combination with the vitamin.—A. M. Copping.

3577

BLITZ, M., EIGEN, E. and GUNSBURG, E. **Vitamin B₁₂ studies. The instability of vitamin B₁₂ in the presence of thiamine and niacinamide.** *J. Amer. Pharm. Assoc.*, 1954, 43, 651-653. [Anal. Control Labs., U.S. Vitamin Corp., Yonkers, N.Y.]

Vitamin B₁₂ was found to be unstable in a solution at pH 4-25 containing vitamin B₁ and nicotinamide. The loss of activity was a function of the concentration of both the substances. Oxidation did not appear to have any part in the reaction.—K. H. Coward.

3578

CANNON, J. R., JOHNSON, A. W. and TODD, A. R. **Structure of vitamin B₁₂. A crystalline nucleotide-free degradation product of vitamin B₁₂.** *Nature*, 1954, 174, 1168-1169. [Univ. Chem. Labs., Pembroke St., Cambridge.]

Further fractionation of the mixture of cobalt-containing acids obtained by alkaline hydrolysis of vitamin B₁₂ gave 3 red fractions, one of which was a hexacarboxylic acid. Red crystalline prisms, obtained by extraction and purification, had ultra-violet absorption spectra close to those of vitamin B₁₂.—A. M. Copping.

3579

BRINK, C., HODGKIN, D. C., LINDSEY, J., PICKWORTH, J., ROBERTSON, J. H. and WHITE, J. G. **X-ray crystallographic evidence on the structure of vitamin B₁₂.** *Nature*, 1954, 174, 1169-1171. [Lab. Chem. Crystallography, Univ. Museum, Oxford.]

Results obtained by X-ray for air-dried vitamin B₁₂, vitamin B₁₂ crystals in the mother liquor, vitamin B₁₂-SeCN and the red degradation product of vitamin B₁₂ described by Cannon *et al.* (preceding Abst.), are presented and discussed. Peaks of electron density were recognised which corresponded to the CN groups, the nucleotide, the phosphorus atom, the ribose group and one nitrogen atom of the benzimidazole nucleus coordinated to the cobalt. A group of largely planar form surrounded the cobalt atom, and the highly unusual arrangement of atoms in this group, as shown by pure vitamin B₁₂, was confirmed in the degradation product. It is considered that further X-ray analysis can give a complete solution of the problem of the structure of vitamin B₁₂.

MADDOCK, A. G. and COELHO, F. P. **The retention of cobalt-60 in vitamin B₁₂.** *J. Chem. Soc.*, 1954, 4702-4704. [Univ. Chem. Labs., Pembroke St., Cambridge.]

In samples of vitamin B₁₂ which had been irradiated *in vacuo* for 1 week, or for 4 weeks in an atomic pile, the retention of radio-activity as ⁶⁰Co was measured after purification by counter-current extraction or by chromatography. The percentage retention was only 0.74 ± 0.05 in the sample exposed for 1 week and 1.9 ± 0.1 in the second sample. Heat treatment did not affect the amount of radio-activity retained. The results confirmed the observations of Lester Smith (*Biochem. J.*, 1952, 52, 384), not those of other workers who reported higher retention values.

DE BELLA, G. **Vitamina B₁₂ e metabolismo basale nel ratto. [Vitamin B₁₂ and basal metabolism in the rat.]** *Bol. Soc. ital. Biol. sper.*, 1954, 30, 184-187. [Ist. Fisiol., Univ. Naples.]

Basal metabolism was estimated in male rats weighing from 200 to 342 g., which had been maintained for 80 days on a purified diet with or without 15 µg. vitamin B₁₂ per 100 g. diet. The animals had fasted and were at rest. In mg. O₂ per hr., per 100 g. bodyweight, the mean value was 172 for 8 rats given vitamin B₁₂, and 190 for 18 rats of comparable weight not given it. The tests were repeated 10 days later with the same animals, the 8 without the vitamin having in the meantime been given it. The mean values were then 168 and 169.—E. M. Hume.

RABBI, A., MARCHETTI, M. and VIVIANI, R. **Iper-tiroidismo sperimentale e vitamina B₁₂ nel fegato di ratto. [Experimental hyperthyroidism and vitamin B₁₂ in the rat's liver.]** *Bol. Soc. ital. Biol. sper.*, 1954, 30, 442-443. [Ist. Chim. Biol., Univ. Bologna.]

Vol. 25, No. 3

Rats weighing from 80 to 120 g. were maintained on the diet of Rando and Causseret (Abst. 3159, Vol. 17) with or without 1000 µg. DL-thyroxine daily for 10 days. In the liver, vitamin B₁₂ was estimated with *Lactobacillus leichmannii*. For rats given and not given thyroxine, respectively, the values, in µg. per g. dry liver, were for total vitamin B₁₂ 658 and 347, for the vitamin after treatment with NaOH 200 and 181, and for the vitamin after treatment with KCN 711 and 399.

DENTON, C. A., KELLOGG, W. L., SIZEMORE, J. R. and LILLIE, R. J. **Effect of injecting and feeding vitamin B₁₂ to hens on content of the vitamin in the egg and blood.** *J. Nutrition*, 1954, 54, 571-577. [U.S. Dept. Agric., Agric. Res. Serv., Animal and Poultry Husb. Res. Branch, Beltsville, Md.]

Hens which had been depleted of vitamin B₁₂ for 6 months were given orally or parenterally amounts of crystalline vitamin B₁₂ ranging from 3 to 50 µg. daily. Eggs were collected during the period after administration when the vitamin B₁₂ content of the yolk was found to be fairly constant. The vitamin B₁₂ activity was estimated by the U.S. Pharmacopoeia 1950 method. Eggs from the hens injected with vitamin B₁₂ reached their highest vitamin B₁₂ content after 10 days, those from hens ingesting the vitamin after 18 days. On the average, about 33 per cent. of the daily dose was deposited in the eggs after injection and about 20 per cent. after ingestion. When the larger amounts of vitamin B₁₂ were given, the efficiency of transfer to the egg was diminished. Newly hatched chicks contained about as much vitamin B₁₂ as the eggs. When the dose of vitamin B₁₂ was 3 or 5 µg., the blood of injected hens contained twice as much activity as the blood of hens ingesting the vitamin, the proportion being about the same as for the eggs. When the hens ingested 10 or 25 µg., increases in the blood values were small; injection of these amounts caused large increases in the blood values, but they were not reflected in the vitamin B₁₂ content of the eggs.

FERGUSON, T. M. and COUCH, J. R. **Further gross observations on the B₁₂-deficient chick embryo.** *J. Nutrition*, 1954, 54, 361-370. [Dept. Poultry Husb., Texas Agric. and Mech. Coll. System, College Station.]

Eggs from hens which had been depleted of vitamin B₁₂ for 4 weeks were incubated and the embryos removed on the 17th day. Of 291 embryos examined, 23 per cent. were classed as deficient in vitamin B₁₂, judged by the external characteristics described by Olcese *et al.* (Abst.

3487, Vol. 20). The embryos were poorly feathered and oedematous, with enlarged thyroid glands and haemorrhages in the yolk sacs. The digestive tract was thin-walled and the muscles small and tendinous. About 40 per cent. of the embryos had a fatty liver with haemorrhagic areas, and 46 per cent. had a pale, dilated, irregularly shaped heart, which was often haemorrhagic. Some of the embryos that were apparently normal externally showed these internal signs of the deficiency. Fatty kidneys, which were sometimes haemorrhagic, and haemorrhages in the crop, gizzard, duodenum, ileum and peritoneal regions occurred. When vitamin B₁₂ was injected into the parent hens or into their eggs before incubation, the abnormalities were prevented.—E. M. Cruickshank.

MEHRING, A. L. (Jr.), TITUS, H. W. and WADDELL, J. The effect of adding methionine and vitamin B₁₂, singly and together, to a corn-soybean diet for laying chickens. *Poultry Sci.*, 1954, **33**, 1191-1197. [Lime Crest Res. Lab., Limestone Products Corporation of America, Newton, N.J.]

Groups of pullets were given for 48 weeks a basal all-vegetable ration, alone or supplemented with DL-methionine or vitamin B₁₂ or both. Although gain in weight, egg production and amount of feed required to produce a given number of eggs were not significantly influenced by the supplements, the hatching capacity of the fertile eggs was improved. On the basal diet alone the average percentage hatched was 70.2 compared with 77.5 and 81.2 on the diets supplemented with DL-methionine and vitamin B₁₂, respectively. When the supplements were combined the percentage was 88.—E. M. Cruickshank.

3588

WELCH, B. E., PERRETT, R. W., CLEMENTS, J. H. and COUCH, J. R. The relation of vitamin B₁₂ to egg yolk storage of folic acid. *J. Nutrition*, 1954, **54**, 601-608. [Dept. Poultry Husb., Texas Agric. Exp. Stat., College Station.]

Pullets were given a basal diet of soya bean protein, glucose, salts, soya bean oil and the required vitamins other than vitamin B₁₂ and folic acid. When 30 and 500 µg. of vitamin B₁₂ per kg. were added to the basal diet the folic acid content of the eggs increased, respectively, to 278 and 529 from 176 µg. per g. yolk, while the content of citrovorum factor increased to 48 and 47 from 36 µg. per g., respectively. The vitamin B₁₂ content of the yolk was not influenced by folic acid supplements up to 400 mg. per kg. diet. Addition of vitamin B₁₂ to the basal diet increased the hatching capacity of the eggs, but addition of folic acid was without effect.—E. M. Cruickshank.

3589

MISTRY, S. P., VADOPALAITHE, I., CHANG, I., FIRTH, J. and JOHNSON, B. C. Vitamin B₁₂ and transmethylation in pig, chick, and rat liver homogenates. *J. Biol. Chem.*, 1955, **212**, 713-722. [Div. Animal Nutrit., Univ. Illinois, Urbana.]

Weight gain and the vitamin B₁₂ content of the liver were studied in baby pigs, chicks and rats kept for from 4 to 6 weeks on basal diets with or without vitamin B₁₂. Growth was retarded in all the animals and there was a great decrease of vitamin B₁₂ in the liver of pigs and chicks deprived of the vitamin, but no significant change in the amount in the livers of deprived rats. Creatine formation was studied with homogenates of pig liver, and methionine formation with liver from pigs, rats and chicks and from normal guinea-pigs and oxen. No significant differences in transmethylation processes were found between normal and deficient pigs or chicks. In deprived rats transmethylation decreased, but it was considered that conditions other than lack of vitamin B₁₂ may have caused the change. From the whole study it appeared that vitamin B₁₂ was not involved in direct transmethylation.

3590

JOHNSON, B. C., FIRTH, J. and MISTRY, S. P. Vitamin B₁₂ and choline synthesis from glycine *in vivo*. *Arch. Biochem. Biophys.*, 1955, **54**, 467-473. [Div. Animal Nutrit., Univ. Illinois, Urbana.]

The effect of vitamin B₁₂ on methyl synthesis for choline formation was studied in baby pigs given a synthetic milk diet containing α-protein from soya bean, lard, Cerelease, methionine, mineral salts and vitamin supplements and 1 per cent. added glycine. One group received vitamin B₁₂ and the other did not. Those lacking vitamin B₁₂ showed loss of appetite and became very weak by the sixth week of the experiment, and their livers were fatty; those of pigs given vitamin B₁₂ showed no fatty infiltration. The vitamin B₁₂ content of the livers was about 10 times greater in pigs given vitamin B₁₂. The results suggest that vitamin B₁₂ is required for synthesis of methyl groups and that glycine serves as a methyl precursor only in presence of vitamin B₁₂.

3591

SACHDEV, J. C. Vitamin B₁₂ and fatty livers in pancreatic duct ligated rats. *Indian J. Med. Res.*, 1955, **43**, 39-42. [Dept. Physiol., Mahatma Gandhi Mem. Med. Coll., Indore, M.B.]

The pancreatic duct was tied in 40 rats weighing from 200 to 250 g., and 10 had a sham operation.

N.A. and R., July 1955

All received a choline-free basal diet and one group of the rats with the duct tied was given vitamin B₁₂ by subcutaneous injection. All the rats with the duct tied had severely fatty livers after 40 days whether they had received vitamin B₁₂ or not. The livers contained 50 per cent. more fat than those of the rats subjected to the sham operation. It appeared that ligation of the pancreatic duct interfered with absorption of essential nutrients to such an extent that vitamin B₁₂ was unable to exert any protective effect.

SORICE, F. Sulla azione di risparmio di alcuni antibiotici nei confronti della vitamina B₁₂. [Sparing effect of some antibiotics for vitamin B₁₂.] *Rend. Ist. Super. Sanità, Rome*, 1954, 17, 940-948. French, English and German summaries.

Of 4 groups of from 15 to 20 rats weighing from 40 to 60 g., given a complete, purified diet containing, per kg., folic acid 2 mg. and vitamin B₁₂ 100 µg., 3 groups received the diet without folic acid or vitamin B₁₂. Two of the groups thus deprived were given 0.05 per cent. of aureomycin or of penicillin. For the first 5 days the diet was given without either of the vitamins or of the antibiotics; the experiment was then continued for 45 days. Weight increase was somewhat superior in the group having the complete diet; differences between the other 3 groups were not statistically significant. In the blood there were no significant differences between the values for red or white cell count or Hb.—E. M. Hune.

3593

HOPPER, J. H. and JOHNSON, B. C. A study of the utilization of pseudo vitamin B₁₂ by the dairy calf. *J. Animal Sci.*, 1955, 14, 272-275. [Dept. Animal Nutrit., Univ. Illinois, Urbana.]

Calves maintained on a synthetic diet with soya bean protein were given supplements of vitamin B₁₂ or pseudovitamin B₁₂. Those having pseudovitamin B₁₂ showed poor growth and after 17 weeks their livers gave much less vitamin B₁₂ activity for both *Bacterium coli* and *Ochromonas malhamensis* than those of calves given vitamin B₁₂.

A. M. Copping.

3594

TEERI, A. E., ENOS, H. F. (Jr.), POMERANTZ, E. and COLOVOS, N. F. The excretion of vitamin B₁₂ by dairy cattle. *J. Animal Sci.*, 1955, 14, 268-271. [New Hampshire Agric. Exp. Stat.]

Vitamin B₁₂ was estimated with *Lactobacillus leichmannii* in urine and faeces from 8 cows. Very little was found in the urine but the amount in the faeces was 40 to 55 times the intake in cows

aged from 3 to 7 years and 10 to 30 times in yearling heifers. This is taken to indicate rich synthesis of vitamin B₁₂ in the rumen.

3595

HINE, D. C. and DAWBURN, M. C. (with SMITH, J.) The determination of vitamin B₁₂-activity in the organs and excreta of sheep. 2. The influence of cobalt on the production of factors possessing vitamin B₁₂-activity in the rumen contents of sheep. *Austral. J. Exp. Biol. Med. Sci.*, 1954, 32, 641-652. [Div. Biochem., C.S.I.R.O., Adelaide.]

(For part 1 see Abst. 4482, Vol. 24.) Vitamin B₁₂ was estimated by 4 microbiological methods with a mutant of *Bacterium coli* in plate cultures, and *Bact. coli*, *Lactobacillus leichmannii* and *Ochromonas malhamensis* in tube cultures, in rumen contents from sheep with a rumen fistula and from intact sheep. The sheep were having cobalt-deficient diets with or without 1 mg. Co daily by mouth. With the Co supplement the vitamin B₁₂ activity of the rumen contents increased, and a steep fall occurred in the first 3 days after the supplement was withdrawn. If the sheep maintained its feed intake there was no further decrease in the vitamin B₁₂ activity of the rumen contents after a week without supplement. The true vitamin B₁₂ value, as measured by *Ochromonas*, was always less than the total vitamin B₁₂ activity measured by other methods. The highest activities were obtained with the *Bact. coli* plate-culture method.—A. M. Copping.

3596

KLEINSORGE, H., MORIGEROWSKI, E. and RÖSNER, K. Bleianämie und Vitamin B₁₂. [Lead anaemia and vitamin B₁₂.] *Ztschr. ges. inn. Med.*, 1954, 9, 903-906. [Med. Poliklin. Innere u. Nervenkrankh., Univ. Jena.]

Studies of bone marrow and blood were made in rabbits given sublethal doses of lead acetate. The lead anaemia could be cured rapidly by administration of vitamin B₁₂, and the vitamin appeared primarily to stimulate blood regeneration in the bone marrow. Vitamin B₁₂ given at the same time as lead acetate prevented the deterioration in general condition as well as the anaemia. The results are discussed with reference to findings of some earlier investigators, that liver extracts did not give protection against lead anaemia.

RIGDON, R. H., COUCH, J. R., BRASHEAR, D. and QURESHI, R. T. Effect of vitamin B₁₂ on selenium poisoning in the rat. *Arch. Pathol.*, 1955, 59, 66-72. [Lab. Exp. Pathol., Univ. Texas Sch. Med., Galveston.]

Rats received a standard ration of Purina chow, to which was added 0.05 mg. Se per g. Animals that took this diet for 33 or 48 days had nearly twice as much vitamin B₁₂ in their livers as animals on a similar diet without Se. In a longer experiment, rats given Se for 17 weeks stored somewhat less vitamin B₁₂ than rats not given Se. The loss of weight and liver damage in rats given Se was not prevented by subcutaneous injection

of 200 µg. vitamin B₁₂ daily, but in a group of 4 recovering after withdrawal of Se from the diet, vitamin B₁₂ hastened the process of repair.

It is suggested that the retention of vitamin B₁₂ in the liver is reduced when it is damaged by Se, and that the regenerating cells either utilise a greater quantity of it, or are unable to store vitamin B₁₂ like normal cells.—D. Dunnean.

OTHER B VITAMINS

3598

SHERMAN, W. C., SCHILT, H. L. and SCHAEFFER, H. C. The use of depleted rats for investigations of vitamin B₁₂ and unidentified factors. *J. Nutrition*, 1955, 55, 255-264. [Nutrit. Res. Labs., Ralston Purina Co., St. Louis, Mo.]

Weanling rats depleted of vitamin B₁₂ were prepared by maintaining breeding females during pregnancy and lactation on a diet containing only vegetable protein. The young were given a more restricted diet at weaning with protein from vegetable sources only. Growth was increased by addition of vitamin B₁₂, but not by pseudovitamin B₁₂. Weight increase was greater when fish solubles, dried liver, liver extract, dried whey and other sources of unidentified growth factors were added to the diet. Addition of vitamin B₁₂ with dried whole liver, liver extract, fish solubles or dried whey produced the greatest weight gains. Antibiotics, malt sprouts, liver residue, lyxoflavin, 3-nitro-4-hydroxyphenylarsonic acid and mucin appeared to contain no unidentified growth factors. Grass juice factor and orotic acid gave very small responses.—A. M. Copping.

3599

RABBI, A. and PICCIONI, M. Azione della colina nella carenza del FPA della caseina. [Action of choline in deficiency of the animal-protein factor of casein.] *Bol. Soc. ital. Biol. sper.*, 1954, 30, 443-445. [Ist. Chim. Biol., Univ. Bologna.]

The protection has already been described (Abst. 2992, Vol. 23) that is exercised by choline against the fatal effects for the young of the first and second generation of rats fed on a diet containing purified casein (see Absts. 425, 3529, 3530, 4896, Vol. 21; 4386, Vol. 23; Title 1851, Vol. 24). The diet caused also histological changes in the liver which, it is now reported, were much less severe when choline was given.—E. M. Hume.

3600

MORUZZI, G., RABBI, A., PICCIONI, M. and DINA, M. A. Insorgenza di neoplasie nel ratto a dieta carente di fattore proteico animale

(FPA). [Occurrence of neoplasms in rats on a diet without animal-protein factor (APF).] *Internat. Ztschr. Vitaminforsch.*, 1955, 25, 384-391. [Inst. Biochim., Univ. Bologna, French, German and English summaries.]

A fuller account is given of experiments already briefly reported (Abst. 3115, Vol. 24), in which rats maintained on a diet containing 5 per cent. casein thrive when the casein was crude, but if it was purified they suffered ill effects which became more severe in later generations maintained on the same diet. When 50 rats of the first generation reared on the diet were kept for 7 months or more on the same diet, 25 of them developed neoplasms, and 8 of them showed pre-cancerous changes in the mucous membrane of the respiratory organs. The neoplasms were sarcomas and fibro-adenomas.

TENTORI, L. and VIVALDI, G. Sindrome mortale caratterizzata da manifestazioni a carico del sistema nervoso nel ratto alimentato con una dieta sintetica purificata contenente sulfonamidoguanidina. [Fatal syndrome characterised by neurological signs in rats fed on a purified synthetic diet containing sulphaguanidine.] *Bol. Soc. ital. Biol. sper.*, 1954, 30, 470-472. [Ist. Super. Sanità, Rome.]

Rats maintained on a purified diet, complete except for folic acid, were given in the diet 2 per

N.A. and R., July 1955

cent. of sulphaguanidine or of succinylsulphathiazole, or 1 per thousand of streptomycin. Folic acid was restored to the diet when it had become clear that the intestinal contents had been sterilised. After from 5 to 6 months, the rats receiving the diet with sulphaguanidine developed a syndrome of low body temperature, weakness, torpor, muscular inco-ordination, tremors and finally attacks like those of tetany lasting a minute or two. Death occurred within from 24 to 48 hr. of the syndrome's onset. The syndrome did not occur with either of the other antibiotics. It was not prevented by any of the known vitamins, but was prevented by 5 per cent. in the diet of the dried, powdered faeces of normally fed rats. There were changes in the thyroid gland like those found in rats treated with thiouracil, and degenerative changes in the central nervous system.

E. M. Hume.

3603

TENTORI, L. and VIVALDI, G. *Sindrome mortale caratterizzata da manifestazioni a carico del sistema nervoso nel ratto alimentato con dieta altamente purificata contenente solfonamidoguanidina. [Fatal syndrome characterised by neurological signs in rats fed on a highly purified diet containing sulphaguanidine.]* 3. Sulla attività preventiva delle feci di ratti ad alimentazione normale e di alcune frazioni di esse. [3. The preventive effect of faeces of normally fed rats and of some fractions of them.] 4. Relazioni con uno stato di ipertiroidismo sperimentale. [4. Relation to experimental hyperthyroidism.] *Rend. Ist. Super. Sanità, Rome, 1954, 17, 19-32; 33-43.* French, English and German summaries.

3. In earlier experiments (*Rend. Ist. Super. Sanità, Rome, 1950, 13, 670; 1951, 14, 216*; and see preceding Abst.) a fatal disorder was induced in rats given diets lacking folic acid and containing sulphaguanidine.

A standard McCollum diet was used as control, with addition, per 100 g., of dried brewer's yeast

2 g., ascorbic acid 20 mg. and sulphaguanidine 2 g. A purified diet was prepared with percentage composition purified casein 18, sucrose 67, salt mixture 4, butter 9 and cod liver oil 2, to which was added, in mg. per kg., vitamin B₁ 10, riboflavin 20, pyridoxine 10, nicotinic acid 100, calcium pantothenate 100, *p*-aminobenzoic acid 100, ascorbic acid 100, choline hydrochloride 200, inositol 200, menadione sodium bisulphite 50, α -tocopherol 100, and ethyl linoleate 100. To the purified diet were added separately or together sulphaguanidine, folic acid, streptomycin and preparations or fractions of faeces from rats on normal diet or a diet containing streptomycin.

Sulphaguanidine with the McCollum diet produced no nervous syndrome, but with the synthetic diet it regularly produced fatal signs in a high proportion of the rats. Folic acid did not prevent the syndrome, but 5 per cent. in the diet of faeces from rats on stock diet did so. Ether extract of such faeces was not active; the ether-extracted residue was partly active and so were faeces heated to 100° C. for 1 hr. Faeces from animals given the purified diet with streptomycin were partly active; those from rats given the purified diet with sulphaguanidine were inactive.

It is concluded that the protective effect of the McCollum diet depended on the presence in it of an unidentified substance and that the protective effect of faeces depended on the presence of a normal intestinal flora or of some of its products.

4. With the same purified diet containing sulphaguanidine, the addition of 10 per cent. whole liver powder reduced the incidence of the fatal nervous syndrome, but did not prevent it in all animals. Iodinated casein (Protamone) as 0.05 per cent. of the diet prevented the disorder completely. After 3 months on the experimental diet, affected animals had lowered basal metabolism, with average values of — 65.5 per cent.

It is concluded that the syndrome bears some relation to hypothyroidism, but it is not known which is the primary factor.—D. Duncan.

VITAMIN C (ASCORBIC ACID)

3604

SCHAFFERT, R. R. and KINGSLEY, G. R. *A rapid, simple method for the determination of reduced, dehydro-, and total ascorbic acid in biological material.* *J. Biol. Chem., 1955, 212, 59-68.* [Clin. Biochem. Lab., Veterans Admin. Centre, Univ. California, Los Angeles.]

Filtrates from whole blood, serum, urine, vegetables and fruit were shaken with Norit charcoal to oxidise the ascorbic acid. Thiourea and 2:4-dinitrophenylhydrazine were added and filtrates

from blood were placed for 5 min., and from urine or food for 10 min., in a boiling-water bath. After cooling, 85 per cent. H₂SO₄ was added, the mixture was allowed to stand for 10 min. and total ascorbic acid was estimated photometrically as dehydroascorbic acid. When charcoal treatment was omitted only dehydroascorbic acid was measured and the amount of reduced ascorbic acid was calculated by difference. At 100° C., 2:3-diketogulononic acid did not significantly interfere with the coupling reaction between dehydroascorbic acid

and 2:4-dinitrophenylhydrazine. The method was accurate and compared favourably with the original one of Roe and Kuether (Abst. 261, Vol. 13).—A. Hepburn.

3605

SCHWARTZ, M. A. and WILLIAMS, J. N. (Jr.) **New procedure for ascorbic acid analysis by the osazone method.** *Proc. Soc. Exp. Biol. Med.*, 1955, **88**, 136–138. [Dept. Biochem., Coll. Agric., Univ. Wisconsin, Madison.]

Total ascorbic acid was estimated by oxidation with 2:6-dichlorophenolindophenol, addition of thiourea and 2:4-dinitrophenylhydrazine to form the osazone, incubation at 37°C. for 3 hr. and finally measurement in a colorimeter after colour development with a 2:3 mixture of 85 per cent. H_3PO_4 and concentrated HCl. Dichlorophenolindophenol was reduced by mixing it with thiourea before the test sample was added to prevent oxidation of ascorbic acid and allow dehydroascorbic acid to be estimated. The method was superior to that of Roe and Kuether (Abst. 261, Vol. 13) and its modifications (Abst. 1225, Vol. 14; 4256, Vol. 16; Bolin and Book, *Science*, 1947, **106**, 451).—A. Hepburn.

GÉRO, E. L'action inhibitrice de l'aneurine sur l'oxydation de l'acide L-ascorbique. 2. L'influence du pH et de la concentration en aneurine; le rôle des diverses parties de la molécule de vitamin B_1 . [Inhibitory action of vitamin B_1 on the oxidation of L-ascorbic acid. 2. Effect of pH and of the concentration of vitamin B_1 ; role of different parts of the vitamin B_1 molecule.] *Bull. Soc. Chim. biol.*, 1954, **36**, 1335–1342. [Lab. Physiol. Nutrit., Centre Nat. Recherche Sci., Paris.]

The inhibition by vitamin B_1 of the oxidation of L-ascorbic acid in the presence of Cu^{++} (Abst. 1919, Vol. 25) was further studied at pH 7 with varying concentrations of vitamin B_1 . It occurred only with concentrations of vitamin B_1 greatly in excess of those of Cu, and the results showed that the theoretical complex of vitamin B_1 and Cu was highly dissociated. Tests with the separate components of the vitamin B_1 molecule showed formation of a complex between Cu and the thiazole portion which was different from the cuprothiamine previously described. Cuprothiamine was formed only when the concentrations of vitamin B_1 and Cu were high and of about the same order.

CIMINO, S. Acido deidroascorbico e metabolismo glicidico. [Dehydroascorbic acid and carbohydrate metabolism.] Acido deidroascorbico e processi deidrogenativi. [Dehydroascorbic acid and dehydrogenation.] *Arch. Sci. biol.*, Bologna, 1954, **38**, 607–613; 614–619. [Ist. Patol. Gen., Univ. Catania.]

Dehydroascorbic acid was prepared and injected into the tail vein of 30 rats weighing from 100 to 130 g. Sugar was estimated in the blood and urine before, and every day or two for 9 days after the injection, and again after 15 and 30 days. The pancreas of some rats was examined histologically. The first dose of 20 mg. dehydroascorbic acid often proved fatal, the rats dying in a state of extreme agitation and respiratory embarrassment. Three further doses of 80 mg. were given to those surviving, one after half an hour and 2 after intervals of 24 hr. Of the 30 rats injected, 9 died, 8 showed no rise in the blood sugar, and 13 showed a large rise; all those showing the rise had sugar in the urine. The hyperglycaemia was not permanent, and the values returned to normal after about 15 days. Histological examination of the pancreas showed no abnormality in the islets of Langerhans. Results of Patterson (Absts. 4888, Vol. 19; 1901, 3534, Vol. 20) were thus only partly confirmed.

The acute respiratory embarrassment of the rats given dehydroascorbic acid was further investigated. The dehydrogenating activity of the watery fraction from homogenates of rat liver was estimated with methylene blue in Thunberg tubes, with and without addition of dehydroascorbic acid, and buffered at pH 6. In the tubes without dehydroascorbic acid, methylene blue was reduced in from 48 to 50 min. In tubes with dehydroascorbic acid there was no reduction.

DE SALEGUI, M., SCHWARTZ, M. A. and WILLIAMS, J. N. (Jr.) **Catabolism of ascorbic acid by animal tissues.** *Proc. Soc. Exp. Biol. Med.*, 1954, **87**, 530-533. [Dept. Biochem., Coll. Agric., Univ. Wisconsin, Madison.]

Homogenates of rat and guinea pig liver were separated by centrifuging into a soluble portion and an insoluble residue. Incubation experiments showed that ascorbic acid was oxidised to dehydroascorbic acid by a heat-stable, non-enzymic substance in the insoluble residue. The soluble portion enzymically oxidised dehydroascorbic acid to a stage beyond diketogulonic acid. A. Hepburn.

3610

ERICSSON, Y. **The effect of ascorbic acid oxidation on mucoids and bacteria in body secretions.** *Acta pathol. microbiol. scand.*, 1954, **35**, 573-583. [Dept. Operative Dent., State Dent. Coll., Stockholm.]

The oxidation of sodium ascorbate by hydrogen peroxide or sodium percarbonate with a trace of copper as catalyst caused depolymerisation with accompanying decrease in viscosity of mucoids from mandibular saliva, nasopharyngeal secretions, pathological lung sputum and gastric juice from patients with gastritis. When the mixture was used as a mouth wash, there was a beneficial effect on acute gingivitis and stomatitis and the coatings of mucus disappeared after a few rinses. *In vitro*, most of the bacteria in cultures from gastric juice were killed during oxidation by the mixture, leaving a small number of staphylococci; bacteria from the mouth were almost all killed. Depolymerisation of bacterial polysaccharide probably occurred. Neither ascorbic acid nor the oxidising agent separately caused depolymerisation or had any bactericidal effect. The same action was shown by ascorbic acid but only to a small extent by dihydroxymaleic acid.—A. Hepburn.

3611

STERN, H. and TIMONEN, S. **The position of the cell nucleus in pathways of hydrogen transfer: cytochrome C, flavoproteins, glutathione and ascorbic acid.** *J. Gen. Physiol.*, 1954, **38**, 41-52. [Rockefeller Inst. Med. Res.]

Studies of cell nuclei of calf thymus and liver tissue showed that cytochrome c reductase, cytochrome c and most other flavoprotein systems were absent. Ascorbic acid and glutathione were present but there was very little glutathione reductase, and no enzymic relation could be established between ascorbic acid and hydrogen transfer in nuclei. Examination of lily anthers at different stages of the mitotic cycle showed a close association between ascorbic acid concentration and the mitotic process. The possible relation

between the anaerobic nature of nuclear metabolism and chromosome function is discussed.

BARAC, G. **Recherches sur la brûlure. Influence de quelques facteurs sur l'effet diurétique de l'acide ascorbique chez le chien brûlé. [Studies of burning. Effect of some factors on the diuretic action of ascorbic acid in the dog after burns.]** *C.R. Soc. Biol.*, 1954, **148**, 1670-1673. [Inst. Clin. Méd., Univ. Liège.]

Adrenaline, arterenol, histamine and the magnesium salt of adenosinetriphosphate tend to appear in increased quantities in the blood from burned dogs, and inhibition of diuresis occurs. The substances were injected singly into intact dogs, at first alone and later mixed with ascorbic acid. Ascorbic acid prevented the inhibition of diuresis by Mg adenosinetriphosphate but not by adrenaline, arterenol or histamine. The diuretic effect of ascorbic acid was strongly inhibited during experimental hypotension and after bleeding.—A. Hepburn.

3613

MEREZHINSKY, M. F., CHERKASOVA, L. S. and KYTSENKO, Z. M. **Soderzhanie askorbinovoi kisloty v tkanyakh belykh kryis s eksperimental'nym perelomom kosti nakhodivshikh-sya v razlichnykh usloviyakh pitaniya. [Ascorbic acid content of the tissues of white rats with experimental fractures, in different nutritional conditions.]** *Vop. Pitan.*, 1955, **14**, 26-30.

Rats weighing about 200 g. were given 3 diets, normal, low-protein with high carbohydrate, and low-protein and carbohydrate with high fat. The diets all had the same calorie value. The animals were subjected to experimental fracture of the femur and, in sub-groups of from 10 to 12 animals, were killed at intervals of from 1 to 60 days after the fracture. The ascorbic acid content of several tissues was estimated and compared with the values for uninjured animals having the same 3 diets. The average values are tabulated.

In the guinea pig, which cannot synthesise vitamin C, such injury was followed by a fall in the vitamin C content of the tissues, but in rats on a normal diet injury was followed by a rise in the ascorbic acid content, in particular of the spleen, adrenal glands, lungs, small intestine, and muscle and bone of the injured limb. With the low-protein, high-carbohydrate diet, increased values for ascorbic acid were found only in the lungs, small intestine and tissues of the broken limb, the changes occurring earlier than in the animals on normal diet. In the group with low protein and carbohydrate and high fat, the ascorbic acid values fell in the liver, kidneys and adrenal

glands, rose in the spleen and lungs, showed a fall and then a rise in the small intestine, and in the injured limb rose even earlier than in the other 2 groups, although not so high.—D. W. Taylor.

HODGES, J. R. A modified adrenal ascorbic acid depletion technique for the bioassay of ACTH. *J. Endocrinol.*, 1955, 12, 152–158. [Dept. Pharmacol., Sch. Pharm., Univ. London.]

The methods of Sayers *et al.* (Abst. 1967, Vol. 18) and Munson *et al.* (quoted by Sayers), in which adrenocorticotrophic hormone (ACTH) was estimated from its depleting effect on adrenal ascorbic acid in hypophysectomised rats, were modified by injecting 20 mg. deoxycorticosterone acetate per 100 g. bodyweight before injection of ACTH in order to prevent mobilisation of endogenous ACTH, and so obviating the need for hypophysectomy. Results with both modified methods were about the same. A linear relationship existed between the logarithms of doses from 0.25 to 16 μ g. of the international standard for ACTH, and the values for the depletion of adrenal ascorbic acid. The method could be performed by comparatively unskilled workers, was as sensitive and as accurate as the Sayers method, and took less time.

RALLI, E. P., DUMM, M. E., KUHLE, W. J. (Jr.), GERSHBERG, H. and BECK, E. M. Effect of extensive denudation on electrolyte and nitrogen balances, ascorbic acid excretion and adrenal cholesterol in rats. *Amer. J. Physiol.*, 1954, 179, 319–324. [Dept. Med., Coll. Med., New York Univ.-Bellevue Med. Centre.]

Balance studies were made on 30 female rats from which a quantity of skin equal to 4 per cent. of the bodyweight had been removed surgically. The diet, given to appetite, contained, per cent., vitamin-free casein 22, sucrose 64, Primex 9, cod liver oil 2 and a salt mixture without Na, Cl or K 3, with vitamins E, K and those of the B complex added; in a drinking solution the animals received 0.05 M KCl and 0.10 M NaCl before and after operation. Of 90 other female rats given similar treatment 26 received 0.01 M KCl in a drinking solution before and after operation, 48 received 0.05 M KCl before and after operation, and 16 received 0.01 M KCl before and 0.05 M KCl after operation; the NaCl content of the drinking solution was 0.10 M, except where 0.01 M KCl was used, when it was sometimes increased to 0.14 M. During the first 2 days after operation, weight, fluid and food intake, and urine output were measured daily; after this time total urine was collected every 48 hr., and analysed for ascorbic acid, total N, Na, K and Cl. After 15 days all the surviving animals were killed, and the weight of the adrenal glands and the concentration in them of ascorbic acid and cholesterol were estimated.

In rats which survived 15 days, food intake was higher than for rats which died before 15 days. Fluid and electrolyte intake was very high in all animals after operation. Rats which survived 15 days retained more K than those which failed to survive. Ascorbic acid excretion increased during the first 2 days after operation and then decreased to below the values before operation. The weight and ascorbic acid and cholesterol concentration of the adrenal glands were higher 15 days after the removal of skin than in intact female rats having the same diet.—G. F. Garton.

3619

FUSI, G. and TILLI, R. Sul comportamento istochimico dei chetosteroidi e dell'acido ascorbico della corticosurrene in corso di irradiazione sperimentale. [Histochemical behaviour of the ketosteroids and of ascorbic acid in the

N.A. and R., July 1955

adrenal cortex during experimental irradiation.] *Sperimentale*, 1954, 104, 34-41. [Ist. Radiol., Univ. Florence.] English summary.

Thirty-six male rabbits, 6 months old, maintained on a normal diet, were subjected in groups of 3 to exposure to X-rays of from 50 to 1500 r over the abdomen, lower limbs or whole body. They were killed 2 hr., or in one group 24 hr., later. In histological preparations of the adrenal cortex, ketosteroids were demonstrated by a staining technique and ascorbic acid with silver nitrate. In comparison with that of normal animals, the ascorbic acid content of the zona fasciculata of the adrenal cortex was hardly affected. The ketosteroid content in all animals irradiated and killed 2 hr. later was reduced in the zona fasciculata and zona reticularis, but not in the zona glomerulosa. In the animals killed 24 hr. after exposure, return to normal was always in progress.—E. M. Hume.

3620

FORBES, J. C. and DUNCAN, G. M. Effect of alcohol intoxication and ACTH on liver ascorbic acid in the guinea pig. *Endocrinology*, 1954, 55, 822-827. [Dept. Biochem., Med. Coll. Virginia, Richmond.]

Intraperitoneal injections for up to 3 consecutive days of an amount of alcohol intoxicating to guinea-pigs gave a significant increase in total liver ascorbic acid after 48 hr. The effect was not observed after 24 hr. but was still apparent after 72 hr. Large amounts of ascorbic acid given before and with the alcohol did not alter the effect, nor did moderate depletion of ascorbic acid, but depletion for 184 hr. before injection abolished the difference between animals given and not given alcohol. Ascorbic acid increased in the liver 24 hr. after the injection of adrenocorticotrophic hormone. The amount and time of decrease in adrenal ascorbic acid produced by the treatments suggested that the rise in the liver was not entirely at the expense of ascorbic acid in the adrenal glands.—A. Hepburn.

3624

SCHRADER, O. L., DE SIQUEIRA, R. and PECHNIK, E. Variedades de goiaba (*Psidium guajava*, L.) genéticamente seleccionadas e vitamina C. [Genetically different varieties of the guava and vitamin C.] *Univ. Brasil Inst. Nutrição Trab. e Pesq.*, 1952, 5, 233-244. English summary.

The 20 varieties of guava compared were obtained from the botanical gardens of São Paulo or from California, and represented the principal types from all over the world. They were grown from seed under identical experimental conditions and fruit was collected from trees 6 or 7 years old.

In 88 samples the ascorbic acid content ranged from 7 to 325 mg. per cent. Several varieties especially selected for size, weight and resistance to pests and disease were also particularly rich in ascorbic acid. Fruit with red or salmon-pink pulp usually contained more than the white or yellow types. The ascorbic acid content rose as the fruit ripened.

In 2 varieties low in ascorbic acid the fruits from branches most exposed to the sun had somewhat higher values.

The results are shown in tables.—D. Duncan.

3625

ANDERSON, E. E., FAGERSON, I. S., HAYES, K. M. and FELLERS, C. R. Ascorbic acid and sodium chloride content of commercially canned tomato juice. *J. Amer. Dietetic Assoc.*, 1954, 30, 1250-1253. [Dept. Food Technol., Univ. Massachusetts, Amherst.]

In 6 samples of each of 40 brands of canned tomato juice, the reduced ascorbic acid value ranged from 1.8 to 29.3 mg. per 100 g., mean 15.6. NaCl values ranged from 0.66 to 1.10 mg. per 100

ml., mean 0.89. The mean NaCl content of 6 samples of canned, unsalted tomato juice prepared in the laboratory was 0.13 mg. per 100 ml.

KYZLINK, V. Antioxydační opatření a ztráty vitamínu C při sterilisaci ovocných konserv. [Anti-oxidative mechanisms and loss of vitamin C during the sterilisation of canned fruit.] *Výživa lids.*, 1954, 9, 139-141. [Fac. Food Tech., Chem. Tech. Univ., Prague.]

Sterilisation of fruit should be accompanied by rapid inactivation of the enzymes. Loss of vitamin C during preservation is considerably reduced by dipping the fruit for several hours in a 30 per cent. solution of sugar saturated with CO_2 .—M. Jančařík (Czechoslovakia).

3627

RUBINO, F. Sul contenuto in acido ascorbico del succo di limone sottoposto alla "flash pasteurisation". [Ascorbic acid content of lemon juice subjected to flash pasteurisation.] *Bol. Soc. ital. Biol. sper.*, 1954, 30, 244. [Ist. Fisiol., Univ. Palermo.]

Flash pasteurisation, in which the juice is exposed for from 5 to 40 sec. to a temperature of 95° C., has recently been applied to the commercial preparation of lemon juice. In 16 samples of juice, the mean ascorbic acid content, in mg. per 100 ml., estimated by the method of Tillmans, was 55 before flash pasteurisation and 50 after it.—E. M. Hume.

3628

MALAKAR, M. C., BANERJEE, S. N. and GUHA, B. C. Studies on the effect of canning and storage on the nutritive value of some common vegetables. 1. Changes in ascorbic acid in cabbage. *Indian J. Med. Res.*, 1955, 43, 23-29. [Nutrit. Res. Unit, Indian Coun. Med. Res., Univ. Coll. Sci. Technol., Calcutta.]

Ascorbic acid was estimated by the 2:6-dichlorophenolindophenol method in samples of cabbage fresh, 5, 30 and 60 min. after blanching for 4 min. at 82-2° C., after canning in 1.5 per cent. salt solution at 10 lb. pressure for 30 min.,

and after storage in cans at Indian temperatures, about 30° to 40° C. for 7 days and 1, 2, 3 and 6 months.

The mean ascorbic acid content of the fresh cabbage was 4.10 mg. per g. on a dry basis. Mean loss on blanching and canning was 92 per cent.; about one-third of this was due to the blanching. Of the remaining ascorbic acid, about one-quarter was lost during the first week's storage; thereafter there was little change until after 2 months; after 6 months only traces were left. Up to 1 month the distribution between solid and liquid was in the ratio of 6:10; thereafter the ascorbic acid content fell more rapidly in the solid than in the liquid. When the cabbage was fortified at the rate of 100 mg. ascorbic acid per 100 g. in the can, about 36 per cent. of the total ascorbic acid was lost during canning, but nearly half remained after 6 months and the ratio of distribution between solid and liquid remained fairly steady, between 3:10 and 4:10.—W. M. Deans.

3629

ROINE, P., WICHMANN, K. and VIHAVAINEN, L. Askorbiinihapon määristä ja säilyvyydestä eri perunalajikkeissa. [Quantity and stability of ascorbic acid in potato varieties in Finland.] *Acta agral. fenn.*, 1955, 83, 71-87. [Dept. Nutrit. Chem., Univ. Helsinki.] English summary.

The vitamin C content of 58 varieties of potato grown in the same field varied widely, the range being from 120 to 49 mg. per 100 g. dry matter. Of 12 varieties grown at the University Experimental Farm at Viik in 3 successive years, Sikkle, Rheingold and Eigenheimer had the highest values each year and Franz and Aquila the lowest, showing that vitamin C content is characteristic of variety. During storage the greatest decrease in vitamin C occurred during the first 3 to 4 months and the loss was most rapid in varieties with the highest vitamin C content; after 6½ months there was no great further loss. About 50 per cent. of the original vitamin C was lost, part of it being converted to dehydroascorbic acid. (From summary.)—J. S. Thomson.

OTHER VITAMINS

3630

LÖVI, M., ÁDOR, V. and GÁBOR, M. Wirkung von Rutin auf die Heilung experimenteller Korneageschwüre. [Effect of rutin on the healing of experimental ulcers of the cornea.] *Acta med. hung.*, 1954, 6, 391-396. [Augenklin., Med. Univ., Szeged.] Russian summary.

Records were made of the healing time, with and without application of rutin, of corneal ulcers produced in rabbits by mechanical injury. In 19 animals in which ulcers were produced simultaneously in both eyes, local treatment with a 5 per cent. rutin salve was without effect on the time of healing. In another series, after the time

N.A. and R., July 1955

of spontaneous healing of the ulcer in one eye had been recorded, a similar ulcer was produced in the other eye, and daily intravenous injections were given of 100 mg. per kg. bodyweight of a 20 per cent. solution of rutin in propylene glycol. For 13 animals the average time of spontaneous healing was 33 days. With intravenous injection of rutin, the average time of healing was 9 days. It is suggested that rutin may act by reducing permeability, and so preventing the complications that arise from iritis in association with corneal ulceration.—M. B. Richards.

3631

KLOSTERMANN, G. F. Über den Einfluss von Rutin auf das Verhalten der Arsenwerte im Blutplasma nach Arsenzufuhr. Tier-experimentelle Untersuchungen mit radioaktivem As⁷⁶. [Influence of rutin on the behaviour of the arsenic values in blood after arsenic administration. Animal experiments with radio-active ⁷⁶As.] *Klin. Wochenschr.*, 1954, 32, 1054-1056. [Klin. Poliklin. Haut- Geschlechtskrankh., Univ. Erlangen.]

From human experiments (*Arch. Dermatol.*, in the press) it had been found that after intravenous administration of rutin, there was increased urinary excretion of arsenic, administered by intramuscular injection 8 hr. previously.

Six rabbits weighing about 2.9 kg. received by intramuscular injection 0.38 mC. ⁷⁶As, equivalent to 3.61 mg. elementary arsenic. One animal died. Blood samples were taken every 4 hr. for the ensuing 24 hr., and 50 mg. rutin was given by intramuscular injection to every animal 8 hr. after the arsenic injection. The supply of radio-active As was insufficient to establish controls. The mean As concentration, ascertained by means of the isotope, for the 6 successive samples of plasma, in µg. per cent., was 101.6, 73.9, 69.7, 70.4, 86.3 and 80.0, so that a definite rise occurred after rutin was given. The effect was shown by all the animals, by some earlier than by others.

It is concluded that the increased excretion of As observed in the human subjects resulted from an increased offer of As by the plasma to the kidneys.—E. M. Hume.

3632

BUKIN, V. N. and EROFEEVA, N. N. Sravnitel'naya P-vitaminnaya aktivnost' katechinov chaya, dubil'nykh veshchestv vinograda i rutina grechikh. [Comparative P vitamin activity of tea catechins, tanning substances from grapes and rutin from buckwheat.] *Dokl. Akad. Nauk. S.S.S.R.*, 1954, 98, 1011-1012. [A.N. Bakh Inst. Biochem., Acad. Sci., U.S.S.R.]

Groups of 20 young rats were given a basal diet

which included, per cent., CaHPO₄ 0.9, MnSO₄·H₂O 0.04, NaCl 0.44 and dried baker's yeast 0.9. Iodised casein, 25 mg. daily, and cod liver oil, 15 ml. per 100 g. diet twice weekly, were given also. The substances being tested were given at the rate of 2 mg. daily [presumably to each rat] and there were 4 groups, rutin being given in 2 forms, as powder or in ampoules. The time of appearance of petechiae under a negative pressure of 200 mm. Hg was measured at the beginning of the experiment and again after 30 days. Each preparation had some vitamin P activity, that of tea catechins being the greatest.—H. Scherbatoff.

3633

MAGIS, N. Nutrition comparée des Tribolium. 3. Action vitaminique de la DL-carnitine et de la DL-dicarnitine chez *Tribolium castaneum* Herbst (insecte, Coléoptère). [Comparative nutrition of *Tribolium*. 3. Vitamin effect of DL-carnitine and of DL-dicarnitine in *Tribolium castaneum* Herbst (insect, Coleoptera).] *Arch. internat. Physiol.*, 1954, 62, 505-511. [Inst. Léon Frédéricq, Univ. Liège.]

For previous parts see Abst. 1052, Vol. 25.

Larvae of *Tribolium castaneum* failed to develop on a purified medium without addition of a growth substance which was present in yeast and yeast extract. The yeast could be replaced by 0.8 µg. DL-carnitine per g. medium. DL-Dicarnitine, added to the medium at the same rate, was as effective as DL-carnitine. Carnitine appeared to be essential for normal metamorphosis and for survival of the nymphs.—A. M. Copping.

3634

BHATTACHARYYA, P. K., FRIEDMAN, S. and FRAENKEL, G. The effect of some derivatives and structural analogs of carnitine on the nutrition of *Tenebrio molitor*. *Arch. Biochem. Biophys.*, 1955, 54, 424-431. [Dept. Entomol., Univ. Illinois, Urbana.]

The effect of certain degradation products, derivatives and analogues of carnitine, on the growth and survival of the larvae of *Tenebrio molitor* was tested. Slight growth-promoting activity was demonstrated in the sulphonic acid and triethyl analogues of carnitine, and activity almost equal to that of carnitine in the O-acetyl derivative and the ethyl ester. Inhibition occurred with γ-butyrobetaine. None of the other compounds tested had any effect on *T. molitor*.—A. M. Copping.

3635

QUATRINI, U. Effetti della vitamina T di Goetsch sull'accrescimento del ratto albino. [Effect of vitamin T Goetsch on the growth of white rats.] *Arch. Fisiol.*, 1954, 54, 166-169. [Ist. Fisiol., Univ. Palermo.]

Seven groups of 5 rats, from 20 to 30 days old, fed on a diet of pasteurised milk, minced meat, bread and greenstuff were given daily for 40 days 0.4 ml. of a preparation of vitamin T received from Professor Goetsch, or 0.4 or 1.2 ml. of a commercial preparation of vitamin T, or 0.4 ml. of the same autoclaved, or 2 µg. folic acid or no treatment (2 groups). Only the preparation from Professor Goetsch had any beneficial effect on growth.—E. M. Hume.

3636

GOETSCH, W. Untersuchungen über Steigerung der Resistenz durch den T-Komplex. [*Increase of resistance by the T-complex.*] *Ztschr. Vitamin-, Hormon-Forsch.*, 1954, 6, 225-233. [Univ. Graz.] English and French summaries.

Of 200 *Drosophila melanogaster* larvae left for 2 hr. in from 30 to 40 per cent. ethanol, the mean percentage that subsequently recovered was 40 when no T-complex had previously been given and 66 when it had been given. Groups of 10 or 12 frog tadpoles, with or without legs, were immersed for 10 min. in 10 per cent. ethanol. When treatment for from 15 to 24 hr. with a solution of from 0.02 to 0.01 per cent. T-complex had previously been given none died, and movement began again in an average time of 38 min. When untreated, 2 died, and recovery of movement required on the average 50 min. Confirmatory experiments of the same type are described. Treatment with T-

complex immediately after treatment with ethanol also promoted recovery. In young frogs, with or without tails, treatment with T-complex accelerated recovery from ether anaesthesia.

3637

HARTMANN, F. and GERTH, H. J. Der Wirkungsmechanismus des meso-Inositol als lipotrope Substanz bei der Bestehen Mangelkonstratte. [*Mode of action of meso-inositol as a lipotropic substance for rats on the Best deficient diet.*] *Arch. exp. Pathol. Pharmacol.*, 1955, 224, 322-326. [Med. Klin., Univ. Göttingen.]

In an experiment with 106 male albino rats weighing from 100 to 120 g., 40 had a normal diet, and 66 had the deficient diet described by Best and his colleagues (*cf. Abst.* 2392, Vol. 21), 36 of them with a supplement of 5 or 10 mg. inositol per 10 g. diet. With the deficient diet the total fat, neutral fat and cholesterol content of the liver were significantly increased and the phosphatide content was decreased. Addition of inositol to the diet reduced the total and neutral fat of the liver, but did not raise the phosphatide. Tests with radio-active ³²P showed a decrease of about 50 per cent. in the rate of phosphatide synthesis in the liver of rats on the deficient diet and only partial restoration in presence of inositol. The mode of action of inositol is discussed and it is considered to be concerned with the liberation of endogenous methionine through increased protein breakdown.

4. PHYSIOLOGY OF NUTRITION

ENZYMES

3638

CARNEVALE, A., COCOZZA, G. and DE ANGELIS, P. Rilievi sulle attività enzimatiche del succo duodenale nel lattante. [*Enzyme activities in the duodenal secretion of infants.*] *Pediatrics*, 1954, 62, 344-362. [Ist. Clin. Pediat., Univ. Naples.] French, English, German and Spanish summaries.

From 2 to 4, usually 3, samples of duodenal juice were withdrawn in the morning after a fast from infants, 7 premature, 8 newborn, and 18 aged from 2 to 12 months. The capacity of enzymes in the juice to split starch, protein and fat was investigated.

All the results for each infant are tabulated and shown in graphs. The amount of starch-splitting enzyme was very small in the premature infants, and in some of the samples taken in the first week of life none was detected. The amount increased with age. It was absent also at first in 2 full-

term infants, but in others was greater than in the premature infants. Above the age of 2 months the values were higher still. Proteolytic activity was never absent and differences between the groups were not great; the values increased somewhat with age, but some high values were found even among premature infants. The fat-splitting enzyme activity was lowest in the premature infants, higher in the newborn infants born at term, and highest in the older babies. The values found are discussed in relation to the infant's natural diet of breast milk.—E. M. Hume.

PRIGMORE, J. R., BOTHWELL, J. W. and WILLIAMS, J. N. (Jr.) Response of liver enzymes and other proteins to amino acid deficient diets. *Proc. Soc. Exp. Biol. Med.*, 1955, 88, 43-46. [Dept. Biochem., Coll. Agric., Univ. Wisconsin, Madison.]

N.A. and R., July 1955

Weanling rats were depleted of protein for 9 days and divided into 4 groups of 8. One group then received the diet of Ramasarma *et al.* (Abst. 3676, Vol. 19), containing 16 per cent. of complete amino-acid mixture, and the other groups received similar diets but without lysine, histidine and methionine, respectively, for 8 days. The rats were then killed for study of liver N and enzymes. Other groups were killed before or after protein depletion for 9 days or after receiving the complete diet for 17 days.

Protein depletion for 9 days reduced bodyweight by 10 per cent. Weights declined slowly on the diets deficient in amino-acids, but on the complete diet the depleted rats gained 50 per cent. in bodyweight in 8 days. During depletion, liver xanthine, succinic and choline oxidases and N all fell. On the histidine-deficient diet xanthine and succinic oxidases and liver N were restored to normal, but choline oxidase was only partly restored. Lysine deficiency prevented restoration of normal levels of all these substances. Succinic oxidase became normal despite methionine deficiency, and N nearly so, but the complete diet was needed to restore choline oxidase to nearly normal. The complete and methionine-deficient diets usually gave results between those obtained with the histidine- and lysine-deficient diets.—D. Duncan.

ALBRECHT, T. W. and JAYNES, H. O. Milk lipase. *J. Dairy Sci.*, 1955, **38**, 137–146. [Dept. Dairying, Tennessee Agric. Exp. Stat., Knoxville.]

Vol. 25, No. 3

Raw skimmed milk contained 2 enzyme systems capable of hydrolysing both tributyrin and ethyl butyrate; each had optima at pH 5.4 and 6.3. Lactic acid was used to adjust pH, since acetic acid, HCl and H₂SO₄ almost completely inhibited lipase activity. The reduced activity with formaldehyde and the substrate specificity indicated that there were 2 enzymes in each system. At pH 5.7 to 6.0 ethyl butyrate was hydrolysed, but tributyrin was not. The esterase was inactivated by formaldehyde.—A. Hepburn.

ILGNER, G. Das Verhalten der alkalischen Darmphosphatase bei den sog. Ernährungsstörungen im Säuglingsalter. [Behaviour of intestinal alkaline phosphatase in the so-called nutritional disorders of infancy.] *Beitr. pathol. Anat.*, 1954, **114**, 398–416. [Kinderklin., Univ. Erlangen.]

Alkaline phosphatase was studied in the intestines of 13 infants, in sections taken 15 to 20 min. after death. In 4 infants who died from perinatal disease, whose intestines were healthy, there was very strong phosphatase activity in the small intestine, but in those with acute or chronic intestinal disease enzyme activity was generally reduced. In 2 infants there was no reaction in the middle and lower part of the small intestine. The reduction of the phosphatase content of the intestinal mucosa is regarded as an indicator of diminished function, because dietary and rachitic influences could be excluded.—M. B. Richards.

3646

DICKIE, N., ROBINSON, M. I. and TUBA, J. The role of alkaline phosphatase in intestinal absorption. 3. The effects of various fatty acids on levels of the enzyme in intestinal mucosa.

TUBA, J. and DICKIE, N. 4. The effects of various proteins on levels of the enzyme in intestinal mucosa. *Canad. J. Biochem. Physiol.*, 1955, **33**, 83–88; 89–92. [Dept. Biochem., Univ. Alberta, Edmonton.]

For part 2 see Abst. 2078, Vol. 25.

3. Alkaline phosphatase was estimated in homogenates of intestine and occasionally in serum from fasted rats fed on fatty acids made palatable with casein. Casein was found to affect intestinal phosphatase and was replaced by wheat gluten,

The increase in intestinal alkaline phosphatase after feeding varied inversely with the chain length of butyric, lauric, palmitic and stearic acids. Oleic acid produced the greatest increase, but this was abolished when choline was included.

4. Alkaline phosphatase in intestinal homogenates from rats was significantly higher 6 hr. after consumption of casein or vitellin than in fasting rats. Lactalbumin, egg albumin, zein, gelatine and wheat gluten had no effect.

A. Hepburn.

MARSH, C. A. A glucuronic-decomposing enzyme from rumen micro-organisms. 3. Mode of

action, specificity and inhibition by acidic sugar derivatives. *Biochem. J.*, 1955, **59**, 375-382. [Rowett Res. Inst., Bucksburn, Aberdeenshire.]

For parts 1 and 2 see Absts. 3097, Vol. 21 and 1659, Vol. 25.

The enzyme was found to be a true β -glucuronidase and was specific for β -D-glucosidopyranuronic acids. Ester glucosiduronic acids and oxycellulose inhibited the enzyme's action on phenolphthalein glucuronide and are considered to be probable substrates. The most powerful inhibitor was D-glucosaccharo-1 \rightarrow 4-lactone.—D. Duncan.

SHAY, H. and SUN, D. C. H. Stress and gastric secretion in man. 1. A study of the mechanisms involved in insulin hypoglycemia. *Amer. J. Med. Sci.*, 1954, **228**, 630-642. [Dept. Clin. Med., Fels Res. Inst., Philadelphia, Pa.]

The intravenous administration of insulin to a fasting patient with chronic duodenal ulcer produced an increase in secretion of total acid, with 2 or more peaks. When Regitine, an adrenolytic and sympathetic drug, was injected just before the insulin the early secretion was unaltered, but later secretion was prevented. The same results were obtained with a similar patient before and after subtotal removal of the stomach and bilateral vagotomy. It is suggested that adrenaline is liberated by the hypoglycaemic action of insulin and is involved in the stimulation of gastric secretion.—A. Hepburn.

HUNT, J. N. and MACDONALD, I. The influence of volume on gastric emptying. *J. Physiol.*, 1954, **126**, 459-474. [Dept. Physiol., Guy's Hosp., London, S.E.1.]

The quantity in the stomach of a test meal of 2 per cent. pectin with 3.5 per cent. sucrose and phenol red was estimated by the recovery of phenol red. Meals of differing volume were given and withdrawn at different times after administration so that for one subject a composite curve of gastric emptying could be constructed. Reproducible patterns of gastric emptying were formed. The initial rate of emptying was more rapid with larger than with smaller meals. This was followed by exponential emptying in which the quantity leaving the stomach decreased with the size of the meal. If 2 successive meals were given the second passed from the stomach more rapidly than the first.—A. T. Phillipson.

TOLCKMITT, W. Studien über die proteolytischen Verhältnisse des Magensaftes bei Ulcus duodeni unter Berücksichtigung neuerer Forschungsergebnisse. [Proteolytic activity of gastric juice in duodenal ulcer with special reference to results of recent research.] *Deutsch. Ztschr. Verdauungs- u. Stoffwechselerkr.*, 1955, **15**, 1-12. [1. Med. Klm., Univ. Hamburg, Eppendorf.]

At pH 0.9 and 3.6 the mean proteolytic activity of gastric juice was higher in 15 patients with duodenal ulcer than in the same number of healthy subjects, but the curves of protein breakdown did not differ enough to have diagnostic significance.

D. Duncan.

3651

WALKER, L., OLSON, W. H. and NACHELES, H. Basal gastric secretion in the dog. *Amer. J. Physiol.*, 1954, **179**, 473-476. [Dept. Gastro-Intestinal Res., Med. Res. Inst., Michael Reese Hosp., Chicago, Ill.]

The preparation of gastro-duodenal and gastro-antral pouches was described earlier (Abst. 131, Vol. 21). The 10 dogs were fed on ground lean beef and milk with added vitamins and Fe. They were fasted for 18 hr. and basal stomach secretion was then collected every 15 min. for 6 or 6½ hr. in quiet conditions.

In 41 tests on the 10 dogs there was no free acid in 7 tests and no secretion at all in 2. Patterns of secretion varied widely, even though the known conditions were apparently constant. There was no relation between volume and acidity of secretion. It is suggested that the fasting dog has no true basal secretion.—D. Duncan.

3652

NASSET, E. S. and DAVENPORT, A. Canine and human gastric digestion of proteins *in vivo*. *J. Appl. Physiol.*, 1955, **7**, 447-450. [Dept.

N.A. and R., July 1955

Physiol., Sch. Med. Dent., Univ. Rochester, N.Y.]

Stomach contents from a dog were obtained free from duodenal contamination by insertion of cannulae, connected externally, at the pylorus and duodenum. Samples of stomach contents were obtained also by stomach tube from 2 human subjects.

At least 15 amino-acids were found in the gastric juice from the dog, whether egg albumin or zein had been eaten or whether secretion had been induced by the sight and smell of food. Lysine and tryptophan, which are almost absent from zein, were always present. Some amino-acids had evidently originated from enzymes and other proteins present in saliva and gastric juice.

After lactalbumin had been given the amino-acids in human gastric juice rose to a maximum in the first hour.—A. Hepburn.

EWERBECK, H. and JAEGER, W. Über den fermentativen Abbau der Proteine und Fette moderner Säuglingsnahrungen in vitro. [Enzymic breakdown of proteins and fats of modern infant foods in vitro.] *Ztschr. Kinderheilk.*, 1954, **75**, 496-511. [Kinderklin., Univ. Cologne.]

Human milk and 7 infant foods including raw and cooked cow's milk were compared. After 1 hr. in pancreatin at pH 7.4 the greatest production of free fatty acid came from homogenised milk and the lowest from human milk, although the total fat contents were 2.5 and 3.7 per cent., respectively. The rate of fat digestion was also high in homogenised milk, but even higher in human milk. Fat digestion was slow in two-thirds cow's milk with Mondamin and in citric acid milk.

The rate and completeness of protein digestion with regard to the 4-hr. total protein level were greatest for human milk, homogenised milk and the mixtures called Correla and Humana. All the foods except citric acid milk had complete protein digestibility, but some of them took longer. Fresh cow's milk protein is as valuable as that of homogenised milk because it remains longer in the stomach.

Homogenisation is considered to be a valuable method of adapting cow's milk for infant feeding. D. Duncan.

MARŠČEK, V. and HERRBYCHOVÁ, A. Průběh enzymatického štěpení bílkovin. [Enzymic splitting of proteins.] *Sborn. pathofysiol. tráv.*, 1954, **8**, 209-214. [Fats and Oils Res. Inst., Prague.]

The digestive activity of trypsin and pancreatin on casein, meat, dried egg white and soya bean

Vol. 25, No. 3

protein was studied. From the beginning of hydrolysis the amino-acids are split off from animal proteins in the same ratio as they have in the protein. Aspartic acid, glutamic acid, serine, glycine and threonine are split off in smaller quantities from plant proteins.—M. Prokšová (Czechoslovakia).

3655

RAYNAUD, P. L'azote total dans les réservoirs gastriques des bovidés. [Total nitrogen in the gastric contents of cattle.] *Arch. Sci. physiol.*, 1955, **9**, 35-50. [Lab. Physiol. Gén., Fac. Sci., Toulouse.]

Total N and dry matter were estimated in samples of contents of rumen, omasum, abomasum and duodenum obtained from cattle at the slaughterhouse, after starvation for about 24 hr.

The mean values in mg. N per 100 g. dry matter were rumen 1705, omasum 2110, abomasum 2404, duodenum 3479. The rising proportion of N depends on absorption of dry matter constituents other than N and on addition of N from secretions or desquamated epithelium. When the abomasum was divided into 2 parts for sampling the trend was found to be reversed in this organ; the mean values in mg. N per 100 g. dry matter were 2575 in the anterior and 2214 in the posterior part. The increase in the anterior part is ascribed to secretion of gastric juice, the fall in the posterior part to absorption of nitrogenous compounds.

The N content in terms of fresh weight of digesta in the different organs was, in mg. per 100 g., rumen 154, omasum 445, anterior abomasum 229, posterior abomasum 240, duodenum 348. All the differences except that between the parts of the abomasum are highly significant. The causes of the changes are discussed.—D. Duncan.

HILL, K. J. Continuous gastric secretion in the ruminant. *Quart. J. Exp. Physiol.*, 1955, **40**,

32-39. [Agric. Res. Coun., Inst. Animal Physiol., Babraham, Cambridge.]

Secretion of gastric juice by innervated pouches in sheep and goats continued during a 48-hr. fast with only small decreases in acidity and volume produced. Emptying the rumen, however, caused cessation of gastric secretion. This and other evidence suggests that the continuous flow of gastric juice into the abomasum is due to the continual entry of food into that organ. In fasting animals onward passage of food is in progress up to 48 hr.—A. T. Phillipson.

KREMEN, A. J., LINNER, J. H. and NELSON, C. H.
An experimental evaluation of the nutritional importance of proximal and distal small intestine. *Ann. Surg.*, 1954, **140**, 439-447 (with discussion 447-448). [Dept. Surg., Univ. Minnesota, Minneapolis.]

Dogs had from 50 to 70 per cent. of the small intestine removed from continuity and established as a Thiry Vella fistula. The segment removed was either distal or proximal, and in some dogs the ileocaecal valve was by-passed. Metabolic studies were later made with different diets.

The dogs which had the proximal 50 or 70 per cent. of the intestine removed maintained their bodyweights after some initial loss, and absorption of protein and fat was not significantly altered. The dogs with the distal part of the intestine removed lost weight, but in those in which the ileocaecal valve was active the weight eventually became stable after falling by from 15 to 50 per cent., whereas in those with the valve by-passed there was no sign of compensation; one dog survived after the flow through the valve was restored, and regained some weight. In all the dogs with the distal part of the intestine removed there was consistent loss of from 80 to 90 per cent. of the food fat in the faeces, and some increased loss of N. The alterations in transit time of barium meals were not closely related to the changes in absorptive capacity.—D. Duncan.

Effects of mixed foods on the blood levels of glucose, amino acids and chylomicrons. *J. Appl. Physiol.*, 1955, **7**, 443-446. [Dept. Gastro-Intestinal Res. Med. Res. Inst., Michael Reese Hosp., Chicago, Ill.]

The blood glucose curves of dogs fed on glucose were depressed when gelatine or cream or both were given also. Glucose, cream or both depressed the blood amino-acid curve when dogs were given gelatine. Gelatine, glucose or both did not affect the plasma chylomicron curves produced by cream.—A. Hepburn.

3661

WISEMAN, G.
Preferential transference of amino-acids from amino-acid mixtures by sacs of everted small intestine of the golden hamster (*Mesocricetus auratus*). *J. Physiol.*, 1955, **127**, 414-422. [Dept. Biochem. Nutrit., Tufts Coll. Med. Sch., Boston, Mass.]

Sacs of everted small intestine were prepared by the method of Wilson and Wiseman (*J. Physiol.*, 1954, **123**, 116). The sac, filled with a known volume of amino-acid solution, was suspended in a flask with 20 ml. of the same solution under an atmosphere of oxygen with 5 per cent. CO₂ and was kept for 1 hr. at 37° C. with continuous agitation. The fluids from inside and outside the sac were then analysed.

With proline solutions the rate of transference of the amino-acid into the sac, in μ l. per mg. dry weight of sac per hour, was 7.31 when the initial concentration was 5 mM and 14.0 at 20 mM. The rates of transference and the concentration gradients developed for L-amino-acids separately and in combination, each at 20 mM initial concentration, are tabulated. Proline and glycine were transferred more rapidly than histidine and methionine, but lysine, ornithine and glutamic acid were not transferred against a concentration gradient. The rate of transference of methionine was not altered by the presence of other amino-acids, but methionine prevented the transference of proline, glycine and histidine. Histidine reduced the transference of proline and glycine, and proline reduced that of glycine. The changes in concentration gradient reflected the rates of transference. The affinity of methionine for the active mechanism was about 20 times that of proline.

It is concluded that only monoaminomono-carboxylic acids are actively transferred by the intestine, and that they compete with one another for the mechanism.—D. Duncan.

BLANKENHORN, D. H. and AHRENS, E. H. (Jr.) Extraction, isolation, and identification of hydrolytic products of triglyceride digestion in man. *J. Biol. Chem.*, 1955, **212**, 69-81. [Hosp. Rockefeller Inst. Med. Res., New York.]

An improved intubation technique for sampling the contents of the human alimentary tract is described. The technique was applied to 2 men aged 27 and 43 years. The samples of digesta from the jejunum were fractionated by counter-current distribution into bile acids, fatty acids and mono-, di- and triglycerides.

After the subjects had received 25 g. maize oil by mouth 1.3 g. mixed lipids were obtained from the upper jejunal contents, which on fractionation yielded 167 mg., 110 mg. and 45 mg., respectively, of mono-, di- and triglycerides, with 710 mg. mixed fatty acids and 34 mg. cholesterol. After 40 g. synthetic triolein, 1.3 g. of mixed non-acidic lipids was isolated from mid-jejunal contents. This mixture gave, on resolution, 532 mg. monoolein, 186 mg. diolein and 186 mg. triolein, with 47 mg. cholesterol and 33 mg. cholesteryl oleate; at least 1.9 g. oleic acid was also isolated from the intestinal sample.

It has been shown for the first time that diglycerides are formed during the normal digestion of triglycerides in man.—G. A. Garton.

BRUNAUD, M. and NAVARRO, J. Action sur la motricité des estomacs du mouton de quelques esters stables de la choline. [Action on the motility of the sheep's stomachs of certain stable esters of choline.] 1. Choline et carbaminoylcholine. [1. Choline and carbaminoylcholine.] 2. Dérivés méthylés de la choline. [2. Methylated derivatives of choline.] *Bull. Acad. vét. France*, 1954, **27**, 213-217; 219-225 (with discussion 225-226). [Lab. Physiol., Ecole Nat. Vét., Toulouse.]

The movements of the rumen, reticulum and abomasum and their neuromuscular reactions were measured by techniques previously described (Titles 4458, Vol. 23; 572, Vol. 24) in sheep anaesthetised with chloralose. The substances tested were injected intravenously. In mg. per kg. bodyweight, the doses given were choline 1 to 50, carbaminoylcholine 0.001 to 0.01, and acetyl- β -methylcholine and carbaminoyl- β -choline 0.001 to 0.1.

All 4 substances increased the tone of the rumen and abomasum, but had no effect on the reticulum; in small doses they sensitised the muscles of the stomachs to vagus impulses. In large doses all except acetyl- β -methylcholine blocked neuromuscular conduction. Only carbaminoylcholine could excite the motor centre of the stomachs.—E. M. Hume.

3667

BLOMSTRAND, R. The intestinal absorption of linoleic-1- 14 C acid. *Acta physiol. scand.*, 1954, **32**, 99-105. [Dept. Physiol. Chem., Univ. Lund.]

Groups of rats with thoracic duct cannulae were given by stomach tube methyl linoleate-1- 14 C, alone or dissolved in olive oil, or fatty acids obtained by saponification of a mixture of labelled linoleate and olive oil. Another group of rats received in the same way olive oil containing 0.2 per cent. palmitic acid-1- 14 C. Lymph was then collected for 24 hr. and the total fat was extracted. Neutral fat and phospholipins were separated on

columns of silicic acid and the radio-activity of each lipid fraction was then measured. Respiratory CO_2 was collected for estimation of its ^{14}C content.

Whatever the form in which it was given, the linoleic acid absorbed was almost all recovered from the neutral fat of the lymph, though some was metabolised, as was shown by detection of $^{14}\text{CO}_2$ in the respiratory CO_2 . Similarly palmitic acid was almost all found in the lymph neutral fat. All lipid mixtures given were absorbed to the extent of 80 to 90 per cent., and up to 95 per cent. was absorbed by some animals.—G. A. Garton.

3668

BLOMSTRAND, R. On the intestinal absorption of phospholipids in the rat. *Acta chem. scand.*, 1954, 8, 1945-1946. [Dept. Physiol. Chem., Univ. Lund, Sweden.]

Rats with thoracic duct cannulae were given labelled phospholipins, dissolved in olive oil, by stomach tube. The phospholipins, prepared biosynthetically, were labelled with ^{14}C in the fatty acids or the glycerol moiety, or with ^{32}P . Lymph was collected for 24 hr. The lymph fat was then chromatographed on silicic acid and the distribution of radio-activity was studied.

With phospholipins containing ^{14}C -labelled fatty acids, 52 to 98 per cent. of the activity was absorbed; and on the average 65 per cent. of the absorbed activity was recovered from the lymph lipids, mostly in the neutral fat and about 16 per cent. in the phospholipins.

When phospholipins labelled in the glycerol part of the molecule were given, more than 60 per cent. of the administered activity was found in the lymph lipids; from 57 to 72 per cent. of the activity appeared in the neutral fat and 28 to 43 per cent. in the phospholipins.

After ^{32}P -labelled phospholipins were given only about 7 per cent. of the activity was recovered from the lymph.—G. A. Garton.

3669

HERNANDEZ, H. H. and CHAIKOFF, I. L. Do soy sterols interfere with absorption of cholesterol? *Proc. Soc. Exp. Biol. Med.*, 1954, 87, 541-544. [Dept. Physiol., Sch. Med., Univ. California, Berkeley.]

Rats with cannulae in the thoracic lymph duct were given 4- ^{14}C -labelled cholesterol dissolved in olive oil with or without added soya bean sterols. Lymph was collected for 24 hr. and analysed for digitonin-precipitable ^{14}C .

The soya bean sterols depressed the absorption of cholesterol whether as little as 4 mg. or as much as 100 mg. of the labelled sterol was given.

3670

BLICKENSTAFF, D. D. Change in the ability of the intestine to absorb isosmotic NaCl solution following distilled water instillation. *Amer. J. Physiol.*, 1954, 179, 467-470. [Dept. Physiol., Med. Sch., Univ. Oregon, Portland.]

Eleven experiments were made on 2 unanaesthetised, trained dogs with upper jejunal ring fistulas (Blickenstaff, *Amer. J. Physiol.*, 1954, 178, 371).

Filling the jejunal loop with distilled water for about 30 min. significantly reduced the amount of water absorbed subsequently from isosmotic NaCl solution, but the rate of chloride absorption was reduced by an amount not reaching significance.

D. Duncan.

3671

BLICKENSTAFF, D. D. Increase in intestinal absorption of water from isosmotic saline following pitressin administration. *Amer. J. Physiol.*, 1954, 179, 471-472. [Dept. Physiol., Med. Sch., Univ. Oregon, Portland.]

Eleven experiments were made on 5 unanaesthetised, trained dogs with Oni fistulas of the upper jejunum (Blickenstaff and Lewis, *Amer. J. Physiol.*, 1952, 170, 17). Absorption from 0.9 per cent. NaCl solutions in 30-min. periods at 15 cm. water pressure was studied before and after injection of 0.005 and 0.01 units Pitressin per kg. bodyweight.

With the smaller dose of Pitressin there was no significant effect on water absorption, but the increase with the larger dose was significant.

D. Duncan.

3672

FIELD, H. (JR.), DAILEY, R. E., BOYD, R. S. and SWELL, L. Effect of restriction of dietary sodium on electrolyte composition of the contents of the terminal ileum. *Amer. J. Physiol.*, 1954, 179, 477-480. [Veterans Admin. Centre, Martinsburg, W. Va.]

After a period on control diet containing about 85 m. equiv. Na and 14 m. equiv. K daily, 3 dogs were fed on a diet containing only 1 m. equiv. Na. Samples were taken by fistula from the terminal ileum and analysed for Na and K.

Na varied greatly from hour to hour and the values reported were for pooled specimens of multiple samples for each day. Na decreased on the low-Na diet, but K increased. Conservation of Na in the upper digestive tract was indicated and possibly a mechanism for selective absorption or secretion, or both, of Na and K in the ileum, to maintain constant osmolarity. Na decreased in the faeces of 1 dog, K to a less extent. The other 2 dogs had unaltered faecal excretion of Na, but K increased. The colon was thought to be able to conserve Na efficiently during the control period, but not K when this was presented in increased amount in the low-Na diet.—A. Hepburn.

MANGOLD, E. and BEHM, G. Der Einfluss des Rohfasergehaltes im Futter auf die Durchgangszeiten beim Schwein. [Effect of crude fibre of feed on time of transit in pigs.] *Arch. Tierernährung*, 1954, No. 5, Beihefte, 10-22. [Inst. Tierernähr., Humboldt Univ., Berlin.]

The 2 crossbred pigs received first a protein-free diet containing 8 per cent. sugar, 3 per cent. mineral mixture and different proportions of potato starch and pure cellulose in the form of ground filter paper. The marker was fuchsin.

The time for total evacuation of the residues of a meal containing 5 per cent. cellulose was 6 days, and when the cellulose content was raised to 10 and 20 per cent. the time fell to 4 and to 3 days.

In the second study the diet consisted of barley meal and fishmeal with different proportions of cooked potatoes and strawmeal. The transit time for such a feed with 5 per cent. strawmeal was 6 days, and as the strawmeal was increased to 10, 15 and 20 per cent. the time fell to 3 days, 48 hr. and 48 hr. The minimum time thus appeared to be 48 hr.—D. Duncan.

COMPOSITION OF BODY FLUIDS AND TISSUES

BLOOD

3674

SCHULMAN, I., SMITH, C. H. and STERN, G. S. (with FORT, E., BENNEM, B. and PRESTWIDGE, J.) Studies on the anemia of prematurity. 1. Fetal and adult hemoglobin in premature infants.

SCHULMAN, I. and SMITH, C. H. 2. The blood volume in premature infants. 3. The mechanism of the anemia. *Amer. J. Dis. Child.*, 1954, 88, 567-568; 568-575; 575-582; 582-595. [Dept. Paediat., New York Hosp.-Cornell Med. Centre.]

1. The percentage of foetal Hb at birth was estimated in 96 term infants and 36 premature infants of birthweight 2100 g. or less. In all, 337 estimations of foetal Hb were made in premature infants during the first year of life.

The results showed that premature infants have a higher percentage of foetal Hb at birth than term infants. Both synthesise foetal Hb after birth, but premature infants tend to lose foetal Hb at an earlier age than term infants. In the premature infant the concentrations of foetal and adult Hb decrease at the same rate during the first 4 to 6 weeks. After this there occurs a sharp increase in the relative concentration of adult Hb and an abrupt decrease in the rate of fall of foetal Hb. These changes appear to be independent of weight gain.

2. Blood volume was estimated by the dye-haematocrit method in 38 premature infants aged 1 to 94 days.

Total blood volume in ml. per kg. bodyweight levelled off by the seventh week of life after a steady fall from relatively high initial levels. Both red cell volume and total blood volume per kg. bodyweight tended to vary directly with venous haematocrit.

3. Estimations of Hb, red cell count, reticulocyte count and percentage of foetal Hb were made on samples of blood taken from 32 premature

infants in the first 24 hr. of life, weekly during their hospital stay and at intervals of 1 to 2 months during the first year of life. Estimates of blood volume were obtained from the observations on a similar group of infants reported in part 2. Changes with age in weight, Hb, reticulocyte count and body Hb content are shown graphically for 4 infants to illustrate the general trend in the group.

In the premature infant there is, apparently, a depression of haemopoietic activity in the early neonatal period with spontaneous recovery beginning at 5 to 7 weeks of age. During the first 3 to 4 months there is more Fe in the body than is used for Hb synthesis. The need for Fe therapy comes after this, to maintain optimum rates of Hb production.—F. C. Aitken.

HERRERA, A. Determinación del volumen plasmático y sanguíneo en niños distroóficos. [Estimation of plasma and blood volume in dystrophic infants.] *Rev. española Pediat.*, 1954, 10, 791-808.

In 20 dystrophic infants, weights were from 12 to 45 per cent. below a standard curve for normal infants, but heights were nearly normal, differing from the standard by from -13 to +9 per cent. Their surface area, Hb, haematocrit, blood volume and plasma volume are tabulated and the volumes are compared with those of normal infants of similar ages. The percentage of difference fell with advancing age up to 2 years, but in dystrophic infants the mean plasma volume was 18 to 41 per cent. and the blood volume 16 to 38 per cent. below normal. There were high positive correlations between blood and plasma volumes and also between bodyweight and blood volume, similar to those in normal infants. The red cell volume showed a lower correlation with physical measurements than in normal infants, so the plasma volume was the most important component. Regression equations are presented, showing a greater

increase of blood volume with weight in dystrophic infants.

Relative to bodyweight, blood volume per kg. was significantly greater in dystrophic infants, without relation to the degree of dystrophy. Red cell volume was low only in severe dystrophy, when it was compensated by higher plasma volume. Relative to height and surface area the blood volume was nearly normal.—D. Duncan.

HERRERA ORTECHO, E. A. La determinación del volumen plasmático y sanguíneo. 2. En lactantes eutróficos y niños mayores. [Estimation of plasma and blood volume. 2. In eutrophic infants and older children.] *Rev. española Pediat.*, 1954, 10, 685-705. [Lima.] French, English and German summaries.

For part 1 see Abst. 1683, Vol. 25.

Height, weight, surface area, blood and plasma volumes, haematocrit and Hb values are tabulated for 20 healthy infants aged from 3 to 26 months and 16 children aged from 3 to 12 years. The relations between the values were examined statistically and the results are shown in tables and graphs. The increase in blood volume in the first year of life is more in haematocrit than in plasma. There is a high positive correlation between increase in blood volume and in body measurements, especially weight and surface area.—D. Duncan.

WILCOX, E. B., MANGELSON, F. L., GALLOWAY, L. S. and WOOD, P. Children with and without rheumatic fever. 4. Hemoglobin, packed red cells, red and white cell count, sedimentation rate, blood glucose, serum iron and copper. *J. Amer. Dietetic Assoc.*, 1955, 31, 45-51. [Dept. Foods Nutrit., Utah State Agric. Coll., Logan.]

For parts 1 and 2 of this survey see Abst. 5090, Vol. 24 and for part 3 Abst. 4090, Vol. 25. Blood constituents were estimated in the same 131 control children and in 131 children with a history of rheumatic fever.

At all ages girls in the rheumatic fever group showed higher values for sedimentation rate than controls. Values for Hb, packed red cells and red cell counts were higher in the control girls and this is attributed to their better diet. Up to about 12 years of age girls in both groups showed higher values than boys for serum Fe, but the reverse was true after that age. Simple and multiple correlations between blood constituents and sex, rheumatic fever history, age and constituents of the diet showed that age had the greatest effect on Hb, volume of packed cells and red cell count. Rheumatic fever had the greatest effect on sedimentation rate.—J. S. Thomson.

3678

RAMAMURTI, K. A note on the haemoglobin levels of normal Indian students in Rajasthan. *Indian J. Med. Res.*, 1955, 43, 57-59. [Biochem. Lab., Birla Coll. Sci., Pilani, Rajasthan.]

Hb in samples of blood from 112 students was estimated by Sahli's method and by those of King and Gilchrist (Abst. 2929, Vol. 17), Collier (Abst. 914, Vol. 14) and Clegg and King (Title 1829, Vol. 12). Mean values were, respectively, 14.30, 17.00, 16.65 and 16.53 g. Hb per 100 ml. blood. The Sahli method is thought to give low values and the high values given by the other methods are taken as indicating the adequacy of Fe intake. D. Harvey.

LIESEGANG, E. and VOGEL, G. Orientierende Versuche über Veränderungen des weissen Blutbildes verschiedener Tierarten in Abhängigkeit von Nahrungsaufnahme und Nahrungsentzug. [Changes in the white blood cells in different species as related to feeding and fasting.] *Arch. Tierernährung*, 1954, No. 5, Beihefte, 50-59. [Vet. Physiol. Inst., Humboldt Univ., Berlin.]

White cell counts were made in a man, a dog, 4 rats, a wether sheep, a goat, 4 rabbits and 3 hens fed in the ordinary way, fasting and re-fed. In all species there was usually a fall in the leucocyte count during 3 to 5 days of fasting, with overcompensation for the first day or two when feeding was resumed. The fall occurred in the ruminants although the digestive tract in these species does not empty as it does in the non-ruminants.

FFAU, P. Die Serumproteine von Feten, Neugeborenen und übertragenen Säuglingen. [Serum proteins of foetuses, newborn infants and postmature infants.] *Arch. Gynäkol.*, 1954-55, 185, 208-220. [Frauenklin., Univ. Heidelberg.]

Paper electrophoresis by the method of Grassmann (see Abst. 3969 Vol. 25) of the cord blood of 16 foetuses and the blood, taken just after birth and in some again later, of 15 premature infants, 35 mature and 35 with signs of postmaturity showed a steady rise in total serum proteins from 2.5 g. per cent. for foetuses of length 20 to 22 cm. to a mean of 5.8 ± 0.10 for term infants and of 6.2 ± 0.12 for postmature infants; the last value is thought to be artificially raised by loss of water. Changes in the proportions of albumin and α -, β - and γ -globulins at different stages are shown in graphs and tables. Weltmann band and nephelogram studies are reported also.—W. M. Deans.

RUSS, E. M., EDER, H. A. and BARR, D. P. (with RAYMUNT, J.) Protein-lipid relationships in human plasma. 3. In pregnancy and the newborn. *J. Clin. Invest.*, 1954, 33, 1662-1669. [Dept. Med., New York Hosp.-Cornell Med. Centre.]

Blood samples were taken immediately after delivery from 27 women in a New York hospital; blood was withdrawn simultaneously from the placental end of the umbilical cord in 25. Plasma was fractionated and analysed for protein, cholesterol and phospholipins; sometimes moving boundary and paper electrophoresis methods were used to confirm the separation of protein components.

The results supported the findings of others. The concentration of albumin, compared with normal plasma, was low in maternal plasma and the concentrations of α - and β -globulins, phospholipins and cholesterol were high. In the plasma from the umbilical cord the concentrations of total protein, α - and β -globulins, cholesterol and phospholipins were lower than in adult plasma.

NYS, A. L'étude combinée des protéines et des lipoprotéines sériques par électrophorèse sur papier, en particulier dans les syndromes hépatiques, néphrotiques et dans l'athérosclérose. [Combined study of serum proteins and lipoproteins by paper electrophoresis, especially in hepatic and nephrotic syndromes and in atherosclerosis.] *Rev. belg. Pathol. Méd. exp.*, 1954, 23, 329-342. [Clin. Med. B, Univ. Louvain.] English summary.

The method of simultaneous electrophoretic estimation of serum proteins and lipoproteins in parallel chromatograms is described.

In 16 normal subjects of both sexes aged from 15 to 48 years the individual variation in lipopro-

teins was much greater than that in proteins. The total lipids were distributed to the extent of about 25 per cent. in α_1 -lipoproteins, 6 per cent. in α_2 -lipoproteins and 70 per cent. in β -lipoproteins.

In 14 subjects with aortic atheromatosis α_1 -lipoproteins were decreased and β -lipoproteins were increased, and there was always a slight reduction in serum albumin. In 17 patients with obstructive jaundice there was a typical disappearance of α_1 - and α_2 -lipoproteins and an increase of β -lipoproteins; in one patient α_1 -lipoproteins reappeared within a week after surgical correction of the biliary obstruction. In this group α_2 -, β -, and γ -globulins were increased.

In 16 patients with non-obstructive lesions of the liver parenchyma, such as hepatitis and cirrhosis, α_1 -lipoproteins were somewhat low and β -lipoproteins were increased. The serum protein showed increases in γ -globulin and, to some extent, in β -globulin.

The clinical value of such examinations is discussed.—D. Duncan.

GOTTFRIED, S. P., POPE, R. H., FRIEDMAN, N. H., AKERSON, I. B. and DIMAURO, S. Lipoprotein studies in atherosclerotic and lipemic individuals by means of paper electrophoresis. *Amer. J. Med. Sci.*, 1955, 229, 34-40. [Dept. Biochem., Bridgeport Hosp., Bridgeport, Conn.]

Total serum lipids, cholesterol and α - and β -lipoproteins were estimated in 39 normal, 8 atherosclerotic and 17 lipaemic patients aged from 20 to 55 years. Age or sex did not affect the α -lipoproteins in the normal patients, but β -lipoproteins tended to be higher in men in their twenties than in women. β -Lipoproteins were elevated in 6 atherosclerotics compared with corresponding normal subjects but tended to drop as the time from the attack of myocardial infarction increased. In the other 2 they were normal, but in 1 they rose later. High β -lipoproteins were found in 5 of 12 men and 2 of 5 women with lipaemia. The atherosclerotics all showed at least one high total serum lipid value, estimations being made at the most twice in each patient. No apparent relation between lipids, cholesterol and β -lipoproteins was established.—A. Hepburn.

MOORE, N. S., YOUNG, C. M. and MAYNARD, L. A. Blood lipid levels as influenced by weight reduction in women. *Amer. J. Med.*, 1954, 17, 348-354. [Sch. Nutr., Cornell Univ., Ithaca, N.Y.]

Each of 36 women kept a record for 1 week of all food eaten and, for 3 typical days, of all her activities. During the week total lipids, phospholipins and cholesterol were estimated in blood. A reducing diet with about 1400 Cal. daily was then taken and in 6 months 24 of the women, aged between 16 and 66 years, lost weight at from 0.6 to 2 lb. weekly. The 12 others, who did not maintain the diet, did not lose weight. Blood analyses were repeated at intervals of 2 or 3 weeks during the period.

There was no detectable linear relation between total lipids in serum and the change in bodyweight. For phospholipins and cholesterol there were small but significant increases of 0.64 and 0.58 mg., respectively, per 100 ml. serum for each pound of bodyweight lost.—D. Harvey.

3688

GEINITZ, W. Über Serumproteine von Tieren die häufig als Versuchstiere oder zur Gewinnung von Heilseren dienen. [Serum proteins of animals commonly used for research or for preparation of antisera.] *Klin. Wochenschr.*, 1954, 32, 1108-1111. [Inst. Physiol. Biochem., Med. Akad., Düsseldorf.]

Quantitative analysis was made by paper electrophoresis of the albumin and the globulin fractions in the serum of 12 mice, 12 rabbits, 10 horses, 12 cattle, 10 sheep and 12 dogs. All were healthy adults of both sexes, except the dogs, which were all male. The results are tabulated in comparison with those obtained by other workers. The considerable differences for the same species are discussed, and it is recognised that the values are affected by the method used, and by the breed and diet of the animals.—E. M. Hume.

RUSS, E. M. and RAYMUNT, J. Protein-lipid relationships in normal dog plasma: application of Cohen method 10. *Circulation Res.*, 1955, 3, 194-198. [Dept. Med., New York Hosp.-Cornell Med. Centre.]

Plasma from 6 normal dogs was separated into 3 protein fractions by the Cohn method. The plasma lipids, in contrast to those in man, were bound almost exclusively to α -globulins. The cholesterol: phospholipin ratios in whole plasma and in the β -lipoprotein fraction were 0.53 and 0.61 for the dog and 0.84 and 1.25 for man.

A. Hepburn.

3691

BARR, D. P., RUSS, E. M., EDER, H. A., KENDALL, F. E. and ABELL, L. L. Protein-lipid relationships in experimental canine atherosclerosis. *Circulation Res.*, 1955, 3, 199-202. [Dept. Med., New York Hosp.-Cornell Med. Centre.]

Three dogs of each sex were used in this study, which comprised 1 control and 4 experimental periods during which the basal ration was a commercial dog food. Blood samples were taken after 2 months on the basal ration alone; after 50 days, during which each animal was given 50 mg. thiouracil daily; after 21 days with thiouracil as before and 1.0 mg. Estinyl (17-ethinyl oestradiol) daily; after 34 days when the thiouracil and Estinyl treatment was continued, but during which the basal diet was supplemented with 5 per cent. cholesterol; and 3 weeks later when the animals had been fed on the cholesterol-rich diet plus thiouracil and Estinyl for a total of 55 days. Serum cholesterol and phospholipins were estimated, and plasma lipoproteins by microfractionation.

The administration of thiouracil, which caused high plasma cholesterol values, but not atherosclerosis, resulted in no marked alteration in the distribution of plasma lipoproteins. No reversal of the thiouracil effect was seen when the oestrogen was given also. The cholesterol-rich diet with thiouracil caused both atherosclerosis and a significant alteration in the distribution of serum lipoproteins. At every stage in the development of atherosclerosis the males developed higher serum cholesterol and phospholipin values and a higher cholesterol: phospholipin ratio than did the females.—G. A. Garton.

STEIN, W. H. and MOORE, S. **The free amino acids of human blood plasma.** *J. Biol. Chem.*, 1954, **211**, 915-926. [Labs. Rockefeller Inst. Med. Res., New York 21.]

Deproteinised plasma contained 28 ninhydrin-positive compounds identifiable by ion-exchange chromatography. Asparagine, glutamine, α -aminobutyric acid, ornithine and citrulline were present in addition to the usual amino-acids. Hydroxyproline was absent. The amounts of aspartic acid and L- and 3-methylhistidine were extremely small. Glutamic acid was also low. Quantitative estimations were possible of all except glutamine. No peptide was found.

A. Hepburn.

3694

KAEDING, A. **Serumfettuntersuchungen bei Stoffwechselgesunden und Diabetikern. [Serum fat studies in healthy subjects and diabetics.]** *Deutsch. Ztschr. Verdauungs- u. Stoffwechselerkr.*, 1955, **15**, 18-26. [Med. Poliklin., Univ. Rostock.]

Total serum lipids were estimated in 46 non-diabetic patients, 11 patients with mild diabetes of whom 5 were obese, and 12 patients with moderate diabetes who required insulin, fasting and at 2-hr. intervals after a meal of 50 g. fat and 25 g. black bread, before and after treatment with a diet restricted in energy and low in fat but not low in carbohydrate (Abst. 2304, Vol. 23), or, for the obese patients, a reducing diet low in fat and carbohydrate and high in protein. The results are shown graphically.

All the diabetics had fasting serum lipid values nearly twice the normal; diet treatment brought them back to normal. High B.M.R. values in non-obese diabetics and low R.Q. values in all diabetics (see Abst. 1837, Vol. 23) were again found. After the diet treatments they approached normal, except that R.Q. remained desirably low in obese diabetics. The abnormal serum lipid curves of diabetics after the fat-rich meal also approached normal after treatment. It is important to maintain normal blood lipid values in diabetics in view of their tendency to vascular complications.—W. M. Deans.

3695

MOODIE, E. W., MARR, A. and ROBERTSON, A. **Serum calcium and magnesium and plasma phosphate levels in normal parturient cows.** *J. Vol. 25, No. 3*

Comp. Pathol., 1955, **65**, 20-36. [Royal (Dick) Sch. Vet. Studies, Univ. Edinburgh.]

Samples of blood were taken from the mammary or jugular veins of 32 cows, serum Ca and Mg and plasma phosphatase were estimated, and the changes at parturition were studied. Differences between 15 cows having their first or second calf and 17 having their third or a later calf were examined. Serum Ca began to fall 2 days before parturition and the lowest value was reached one day after parturition. In the older cows the fall was greater. Serum Mg rose to its highest value about one day after parturition, and in older cows it reached higher values than in younger.

Inorganic, total acid-soluble and total phosphates all fell during the 24 hr. before parturition and the lowest point was reached at calving, with lower values in the older cows. After parturition there was an immediate rise in these values, more rapid in the younger animals. There was little change in lipid phosphate values, and no difference between the 2 age groups.

These results were thought to confirm the opinion that milk fever is an exaggeration of a normal physiological process.—T. D. Bell.

3696

BOOGAERDT, J. **De toestand van het calcium in het bloed bij de grote huisdieren. [The state of calcium in the blood of the large domestic animals.]** *Thesis, Univ. Utrecht*, 1954, pp. 111. English, German, French and Spanish summaries.

FUCHS, A. R. and FUCHS, F. **Investigations on the plasma phosphate. 2. Diffusibility of the inorganic phosphate of guinea pig serum. 3. Adsorption studies on guinea pig blood.** *Acta physiol. scand.*, 1954, **32**, 363-368; 369-373. [Carnegie Inst. Washington, Baltimore, Md.]

2. Guinea pig serum was shown by dialysis against Ringer or Tyrode solution to contain a non-diffusible P compound. The average amount, estimated as inorganic phosphate, was 8 per cent. of the total inorganic plasma phosphate.

3. Radio-active phosphate added to guinea pig serum was adsorbed more quickly when shaken with BaSO_4 than the original serum phosphate. Control experiments with Ringer or Tyrode solution did not show this effect, nor did foetal plasma. Plasma may contain a labile non-diffusible phosphate, chemically estimated as inorganic phosphate but less readily adsorbed on BaSO_4 .—A. Hepburn.

3698

RECHENBERGER, J. and HEVELKE, G. **Tagesrhythmik des Serumeisens und Leberfunktion. [Liver function and diurnal rhythm in serum**

iron.] *Deutsch. Ztschr. Verdauungs- u. Stoffwechselerk.*, 1953, 15, 12-18. [Med. Klin., Univ. Leipzig.]

The diurnal variations in serum Fe are considered to be merely a manifestation of diurnal variations in liver processes, the maximum serum Fe values corresponding to the peak of activity in the liver cell. Evidence for this is provided by a study of serum Fe in 124 patients with hepatitis; in the acute stage of severe cases the diurnal variations were absent, but in convalescence they reappeared.—W. M. Deans.

KRÁL, J. and ŽENÍŠEK, A. Ztráty aminokyselin potem u těžce pracujících a u sportovců. [Loss of amino-acids in sweat by heavy workers and athletes.] *Čas. Lék. čes.*, 1954, 93, 1155-1163. [Fac. Med., Karl's Univ.] French and Russian summaries.

Sweat was examined from 7 students, not in training, after heavy work on the bicycle ergometer, from 22 metal workers, and from 5 men whose work was in a hot moist atmosphere, preparing the mud baths at Piešťany. The total loss of sweat during the job and per hr., respectively, was, in ml., for the students 700 ± 427 and 700 ± 427 , for the metal workers 3764 ± 1780 and 470.5 ± 222 , and for the mud-bath workers 580 ± 444 and 72.5 ± 56 . The average loss of amino-N in the sweat in mg per hr. and the average concentration in mg. per cent., respectively, for the 3 groups in the same order was 254.9 and 31.4, 64.9 and 10.8, and 7.4 and 10.3; the loss was greatest at the beginning of the work. Estimations were made chromatographically of lysine, arginine with citrulline, threonine and histidine. Though the losses were considerable, no special measure for replacement was considered necessary, and it was not thought that losses of amino-acids could account for the feeling of fatigue which follows heavy sweating. (From summary.)

3700

ISAKSSON, B. Bile lipids in calves under different nutritional conditions. *Acta physiol. scand.*, 1954, 32, 281-290. [Dept. Med. Chem., Univ. Gothenburg.]

Bile was collected immediately after death from 5 newborn calves less than 1 week old, 6 weanling calves of average age 7 weeks and 6 calves less than 7 months old. Total bile acids, lecithin, cholesterol and cholic acid were estimated on the bile samples; the lipids in the serum and liver of each animal were examined for comparison.

The weanling calves had a higher percentage of cholesterol and lecithin in the bile than the older calves, possibly because of the forage diet of the older animals. The amount of total solids was low in the bile of the newborn calves, probably because the concentrating power of the gallbladder was undeveloped.—G. A. Garton.

REYNOLDS, E. L. The distribution of subcutaneous fat in childhood and adolescence. *Monogr. Soc. Res. Child Development*, 1950, 15, No. 2, pp. xviii + 189.

This monograph from the Fels Research Institute for the Study of Human Development begins with a review of the literature covering 230 references. In the second part group results are presented and analysed. These data are obtained from over 9000 soft tissue X-ray photographs, taken during 12 years from 176 children from age $6\frac{1}{2}$ to $17\frac{1}{2}$ years, 80 infants and 256 adults. In the third part data relating to 19 children have been selected for special study of individual differences. The X-ray material is supplemented by some body measurements, nude photographs, medical and other reports and records of growth.

JOHNSTON, L. C. and BERNSTEIN, L. M. Body composition and oxygen consumption of overweight, normal, and underweight women. *J. Lab. Clin. Med.*, 1955, 45, 109-118. [Dept. Med., Univ. Illinois, Chicago.]

In 17 healthy women aged from 21 to 59 years and of constant bodyweight the bodyweight ranged from 39.8 to 186.4 kg. or from 60 to 284 per cent. of the standard for height and age. The volume of extracellular water ranged from 7.2 to 25.9 litres and total body water from 24.2 to 71.7 litres. Body fat, calculated from the difference between total bodyweight and lean body mass,

N.A. and R., July 1955

ranged from 6.7 to 88.4 kg., lean body mass from 33.0 to 98.1 kg. and cell mass from 19.7 to 68.4 kg. Basal oxygen consumption ranged from 140 to 357 ml. per min. or from 85 to 136 ml. per sq. m. per min.

Surface area was equally well correlated with cell mass and lean body mass; oxygen consumption was equally well correlated with surface area, lean body mass and cell mass. "Obesity tissue" was calculated to contain 24 per cent. cell mass, 6 per cent. extracellular fluid and over 67 per cent. fat.—G. F. Garton.

SIRI, W. E., REYNATFARJE, C., BERLIN, N. I. and LAWRENCE, J. H. **Body water at sea level and at altitude.** *J. Appl. Physiol.*, 1954, **7**, 333-334. [Donner Lab., Univ. California, Berkeley.]

The data referred to 15 medical students at sea level and to 13 men acclimatised to 16,400 ft. or more above sea level. Mean values for body water as estimated and for body fat as calculated were 55.6 and 23.8, 60.6 and 17.0 for the respective groups. The findings are to provide a basis for further studies of changes during and after acclimatisation.—D. Harvey.

3706

ANNIGERS, J. **Total body water in rats and in mice.** *Proc. Soc. Exp. Biol. Med.*, 1954, **87**, 454-456. [Naval Med. Res. Inst., Bethesda, Md.]

Total body water was almost a constant fraction of the fat-free weight in grown normal mice and rats. Body fat had no independent effect on total body water. Total body water was reduced during severe dehydration. It was significantly higher in the weanling rat than in the adult when expressed as a percentage of the fat-free body weight.

TALLAN, H. H., MOORE, S. and STEIN, W. H. **Studies on the free amino acids and related compounds in the tissues of the cat.** *J. Biol.*

Vol. 25, No. 3

Chem., 1954, **211**, 927-939. [Labs. Rockefeller Inst. Med. Res., New York 21.]

Analyses of protein-free extracts of liver, brain, pancreas, muscle, kidney, bladder, plasma and urine from the cat by ion-exchange chromatography revealed 40 components. These included, besides the common amino-acids, ethanolamine, phosphoethanolamine, glycerophosphoethanolamine, 3-methyl-histidine, taurine, asparagine, sarcosine, α - and γ -amino-*n*-butyric acid, β -aminoisobutyric acid, β -alanine, α -aminoadipic acid, ornithine and glutathione. Felinine, a sulphur amino-acid, occurred in large quantity in the urine. Anserine, carnosine and 1-methylhistidine occurred together, mostly in muscle. Bound forms of aspartic acid, other than asparagine, were shown by hydrolysis, and so were conjugates of serine, threonine, proline and lysine.—A. Hepburn.

3709

SMITH, L. C. and ROSSI, F. M. **Quantitative determination of ethanolamine phosphate and free amino acids of normal and neoplastic tissue.** *Proc. Soc. Exp. Biol. Med.*, 1954, **87**, 643-646. [Res. Div., Veterans Admin. Hosp., Hines, Ill.]

The free amino-acids from normal rat and rabbit thymus and rat testes and from neoplastic tissue were estimated quantitatively by ion exchange chromatography.

The amino-acid pattern of a given tissue was fairly constant, but varied with species. Rabbit lymphocytes had considerably more ethanolamine phosphate, glutamic acid and glycine than rat lymphocytes, which were richer in taurine and aspartic acid. Ehrlich carcinoma cells and sarcoma cells growing as free suspensions in the ascitic fluid of mice had similar amino-acid patterns, with large amounts of taurine, glutamic acid, glycine and alanine. Of solid tumours in rats the Bagg reticulum sarcoma contained 1.6 times the total amount of amino-acids in Walker carcinoma cells. Sarcoma cells contained most alanine and glycine, with smaller amounts of proline and ethanolamine phosphate and little taurine. Of the tumour cells only Walker carcinoma cells contained little alanine. Taurine was the most abundant, except in the lymphosarcoma, being much higher than in the normal tissues. Proline, aspartic acid, serine and threonine occurred in small quantity in all the tissues examined.

LÁSZLÓ, J. and SCHULER, D. The role of lipids in the elastolysis of atherosclerotic vessels. *Acta physiol. hung.*, 1954, **6**, 463-469. [Inst. Pathol. Anat., Med. Sch., Univ. Budapest.] Russian summary.

Twenty-four human aortas showing different degrees of atherosclerosis were examined histologically and analysed for phospholipins and total cholesterol.

In accordance with previously published work, the increased amounts of cholesterol found in the pathological tissue were accompanied by only slightly increased amounts of phospholipins. During the progression of atherosclerosis the elastic fibres became more susceptible to elastolysis; this effect is discussed in relation to the lipid content of the vascular wall.—G. A. Garton.

3712

BUCK, R. C. Distribution of acid mucopolysaccharides and lipids in tissues of cholesterol-fed rabbits. *Arch. Pathol.*, 1954, **58**, 576-587. [Dept. Microscopic Anat., Fac. Med., Univ. W. Ontario, London.]

Eight male rabbits were fed on a stock pellet diet to which was added 1 per cent. of cholesterol. After from 3 to 6 months on the diet animals were killed and sections of tissues were stained for lipids and acid mucopolysaccharides. A group of 8 control animals received stock diet only.

After cholesterol feeding foam cell deposits were observed in many tissues, especially in the intima of the blood vessels, kidney, liver, dermis, spleen, stomach, ciliary body, brain and lung. No relation was found between sites of high concentration of acid mucopolysaccharide in the normal animals and sites of foam cell deposits in those given cholesterol. The cytoplasm of foam cells in all tissues contained acid mucopolysaccharide. In early lesions in arteries and other tissues the acid mucopolysaccharide appeared to be derived from foam cells. In older lesions an atheromatous mass was formed by breakdown of foam cells and liberation of cholesterol and acid mucopolysaccharide.

SCHMIDT, G., GREENBAUM, L. M., FALLOT, P., WALKER, A. C. and THANNHAUSER, S. J. The amounts of glycerophosphoryl esters in some

tissues. *J. Biol. Chem.*, 1955, **212**, 887-895. [Res. Labs., Boston Dispensary, Tufts Coll. Med. Sch., Boston, Mass.]

Details are given of a method based on P estimation for quantitative estimation of glycerophosphoryl esters in tissues.

The glycerophosphoryl ester content of lamb, beef, rabbit and dog liver was high; that of livers of rats and laying hens was negligible. When lamb liver homogenates were allowed to autolyse there was no significant change in the glycerophosphoryl ester content; autolysis of beef pancreas or of the mucosa of rat small intestine resulted in large increases in the amounts of glycerophosphoryl esters in the digests.

SOBEL, H., MARMORSTON, J. and MOORE, F. J. Collagen and hexosamine content of femurs of rats. *Proc. Soc. Exp. Biol. Med.*, 1954, **87**, 346-349. [Dept. Biochem., Inst. Med. Res., Cedars of Lebanon Hosp., Los Angeles, Calif.]

Femurs from 57 male and 28 female rats, 1 to 3 months old, were analysed for collagen and hexosamine. Regression equations showed that the logarithms of these constituents were linearly related to the logarithms of bodyweight and femur length. The rate of deposition of collagen in the femur fell slightly with growth, that of hexosamine sharply. The female femur initially contained more collagen and hexosamine, but with growth the difference disappeared.—A. Hepburn.

BRENNER, H. and WILKINSON, J. F. The nucleic acid content of bone-marrow cells in pernicious

N.A. and R., July 1955

anaemia. *Brit. Med. J.*, 1955, i, 379-382.
[Manchester Royal Infirmary.]

Estimations of nucleic acids were made on suspensions of blood or bone marrow containing a known number of nucleated cells per c.mm., so that mean amounts of nucleic acid per cell could be calculated. Sternal marrow samples were taken from 18 patients with classical pernicious anaemia and these were compared with 9 samples from marrows showing normoblastic hyperplasia, which were thought to afford a better comparison than marrow from normal subjects with a high proportion of mature leucocytes. Seven samples of normal blood were examined.

The mean amounts of deoxyribose nucleic acid phosphorus per cell were similar in normoblastic and megaloblastic marrows and less in normal blood. The mean amount of ribose nucleic acid phosphorus per cell was 18.53×10^{-7} μ g. in pernicious anaemia and 10.69×10^{-7} μ g. in active blood regeneration. Accumulation of RNA is therefore a specific feature of the megaloblastic marrow cell, but accumulation of DNA in the marrow may be due simply to the prevalence of cells preparing to divide.—D. Duncan.

3718

LANDBOE-CHRISTENSEN, E. Occurrence of argent-affin cells in the stomach and duodenum in cases of pernicious anemia. *Acta med. scand.*, 1954, 150, 369-375. [Dept. Anat., Univ. Copenhagen.]

Sections were made of stomach and duodenum from 8 patients who died with typical pernicious anaemia, and were stained by the Masson Hamperl silver technique.

In all the subjects silver-staining cells were found; in 7 they were in the stomach and in 6 in the duodenum. The specimens in which they were few or absent were those showing the greatest post-mortem changes. The silver-staining cells in the stomach occurred in ectopic islands among cells of intestinal type, most commonly in the fundus, and not in the pyloric area. In the duodenum they were distributed normally.

It is concluded that earlier reports of the absence of such silver-staining cells in patients with pernicious anaemia arose from delay in fixing the material, since post-mortem changes affect these cells very rapidly.—D. Duncan.

FARQUHAR, J. W. Control of the blood sugar level in the neonatal period.

STEIN, L. Summary of statistical method. *Arch. Dis. Childhood*, 1954, 29, 519-529; 529-530. [Dept. Child Life and Health, Univ. Edinburgh.]

Serial studies of blood sugar and eosinophil counts during the first 10 days of life of 32 normal infants showed no consistent relation between them in the individual infant. The results, though they gave no confirmation of the hypothesis relating neonatal hypoglycaemia and adrenocortical hypofunction, do not invalidate such a hypothesis. F. C. Aitken.

3721

PESCHEL, E. and RACE, G. J. Studies on the adrenal zona glomerulosa of hypertensive patients and rats, with special reference to the effect of dietary salt restriction. *Amer. J.* Vol. 25, No. 3

Med., 1954, 17, 355-364. [Dept. Med., Sch. Med., Duke Univ., Durham, N.C.]

The width of the zona glomerulosa of adrenal glands was measured in 54 patients after death from diseases causing high blood pressure; all had been on salt-free rice diet and in 10 death was relatively sudden. For comparison measurements of glands were made in 20 cases of accidental death, in 15 with cancer of the intestines causing malnutrition and in 13 patients with high blood pressure, whose salt intake had not been reduced. Five groups of rats, normal or hypertensive on normal or salt-free diets or hypertensive and on the salt-free diet with added salt, were studied also. Histochemical estimations were made of the lipids present in the zone. In general the findings for rats agreed with those on the human subjects.

On normal diets the mean widths of zones did not differ in normal and hypertensive subjects, being 136 ± 39 and 130 ± 21 μ , respectively; for the undernourished subjects the mean was 104 ± 25 μ . For all hypertensive patients it was 181 ± 79 μ , and for the 10 selected ones 168 ± 56 μ . The indications in human subjects on the rice diet were that as the width of the zona glomerulosa increased its fat content decreased.

The findings may be interpreted as evidence of increased hormone production without storage.

TALMAGE, R. V. and KRAINTZ, F. W. **Progressive changes in renal phosphate and calcium excretion in rats following parathyroidectomy or parathyroid administration.** *Proc. Soc. Exp. Biol. Med.*, 1954, 87, 263-267. [Dept. Biol., Rice Inst., Houston, Tex.]

Of 150 male rats of 180 to 225 g. bodyweight some had their parathyroids removed and others had subcutaneous injections of parathyroid extract. The rats were given 7 to 10 μ C. of ^{45}Ca or ^{32}P in water and urine was collected 2, 4, 12 and 27 hr. thereafter. The rats were then killed and the blood was collected for estimation of Ca and P.

After parathyroid removal there was an immediate fall in urine P and a rise in urine Ca. Within 27 hr. the excretory rates of both ions had returned to normal, although P continued to be high and Ca low in the serum. When 100 I.U. parathyroid extract was given to intact rats there was an immediate drop in urine Ca and a rise in urine P, although serum Ca had risen and serum P had fallen. Within 27 hr. the excretory rate for Ca had returned to normal or was even higher, while urine P continued to be high. It is suggested that the kidney is directly involved in the action of the parathyroids on Ca and P metabolism.

MOOKERJEE, S. and SADHU, D. P. **The role of thyroid on the mechanism of cholesterol synthesis in the body.** *Indian J. Physiol. Allied Sci.*, 1954, 8, 121-124. [Dept. Physiol., Univ. Coll. Sci., Calcutta.]

Hypothyroidism was induced in rats with methyl thiouracil. The treatment resulted in production of increased amounts of total cholesterol, volatile fatty acids, including acetic acid, and acetone bodies in blood, kidneys, liver, intestine and adrenals. Dehydrogenase activity in the tissues was depressed.

It is concluded that the thyroid regulates oxidation of acetate and acetoacetate through the cyclophorase system and that in hypothyroidism oxidation of these compounds is diminished and they are converted to cholesterol.—G. A. Garton.

3726

VAN DER VEEN, H. E. and HART, P. C. **Onderzoek naar het voorkomen van strumogene stoffen in melk.** [Occurrence of goitrogens in milk.] *Voeding*, 1955, 16, 12-22. [Inst. Vee- teeltk. Onderzoek, T.N.O., Utrecht.] English summary.

Two experiments are described with North Holland Blue cocks as test animals. In the first experiment with 50 cocks, 12 weeks old, in 5 equal groups there were 3 experimental groups given a meal ration with 15.5 per cent. protein and 2.2 times the weight of pooled milk, or of milk from one of a pair of identical twins, one fed on turnips (*Brassica rapa*, var. *rapa*) known to contain goitrogens, and the other fed on fodder beet known not to contain goitrogens. Full details are given of the rations. One control group had the same meal mixture and water only; the other a mixture with 18 per cent. protein and water. Histological examination of the thyroids after 3 weeks showed no evidence of goitrogenic action from about 300 ml. milk daily.

In the second test the cocks were 6 weeks old at the start, there were 3 milk groups as before and 3 control groups, of which 2 were given 50 or 10 mg. methylthiouracil daily for 10 days before slaughter. After 6 weeks there was no evidence of goitrogenic effect. The turnips contained about 10 mg. 1:5-vinyl-2-thioxazolidone per kg., the fodder beet none. The milk groups had about 50 μ g. I daily; the water groups about 36 μ g. If the requirement of young cocks is 100 μ g. I daily the amount supplied could have had no part in preventing goitre.—I. Leitch.

3727

SILBERBERG, R. and SILBERBERG, M. **Skeletal effects of radio-iodine induced thyroid deficiency in mice as influenced by sex, age and strain.** *Amer. J. Anat.*, 1954, 95, 263-289. [Sodgrass Lab., Hosp. Div., St. Louis, Mo.]

Mice of 2 strains, DBA and C57BL, were injected intraperitoneally with 200 μ C. of ^{131}I at one month or with 400 μ C. at 6 months of age. Untreated mice of the same strains acted as controls. Mice were killed at selected dates and the tibiae were examined histologically.

The destruction of the thyroids by the ^{131}I delayed growth and development of the skeleton. There was a decline in susceptibility to loss of the thyroid with advancing age in both strains. Mice of strain C57BL were less susceptible than mice of

N.A. and R., July 1955

DBA strain. The thyroids of the untreated DBA mice were hyperactive, those of the untreated C57 BL mice relatively inactive. The loss of thyroid in the latter strain had not, therefore, such a great effect as in the DBA strain. Since thyroid and oestrogenic hormones have antagonistic effects on bone resorption, the removal of the active thyroids of the females of the DBA strain eliminated a more powerful inhibitor of the oestrogenic hormones than the removal of the comparatively inactive thyroids of the females of the C57 BL strain. Experiments on ovariectomised mice are in progress.

The study is illustrated with photomicrographs showing the delayed growth and ossification of the epiphyseal cartilage of the tibiae and the inhibition of resorption of both cartilage and bone in thyroid deficiency.—B. W. Simpson.

3728

RYAN, E. J. and KIRKWOOD, S. Explanation of the effect of feeding desiccated thyroid on the incidence of dental caries in the rat. *Science*, 1955, 121, 175-176. [Evanston, Ill.]

Reference is made to the work of Muhler and Shafer (Absts. 1047, 1048, Vol. 25), in which reduction of salivary flow by desalination increased the incidence of caries and consumption of dried thyroid reduced it. Evidence is also quoted showing that hyperthyroidism is associated with increased function of the salivary glands and hypothyroidism with low function. It is suggested that the preventive action of dried thyroid may result from an increased flow of saliva or an increase in the concentration of I in saliva, a concept which may both explain the predisposition of some individuals to caries and provide a new method for its control.—D. Harvey.

GARN, S. M. and CLARK, L. C. (Jr.) (with HARPER, R. V.) The sex difference in the basal metabolic rate. *Child Development*, 1953, **24**, 215-224. [Fels Res. Inst., Yellow Springs, Ohio.]

Height, weight, leg muscle diameter (from lateral X-ray photographs) and B.M.R. were recorded for 76 boys and 69 girls aged from 6 to 17 years.

Basal oxygen consumption by age was higher in boys than in girls at all ages, though in the youngest groups the difference was not large. When computed as Cal. per kg. bodyweight the difference was less, but at 13 to 15 years old the boys consumed about 3 Cal. per kg. or 10 per cent. more than the girls. In 27 pairs of boys and girls matched in terms of diameter of calf muscle [not corrected for fat], two-thirds of the figures for boys still exceeded those for the girls. After puberty all the boys consumed more oxygen on each basis than the girls paired with them by age and muscle size.

It is suggested that ketosteroids may produce the higher B.M.R. in boys, which is most marked after puberty.—D. Duncan.

3738

EICHORN, D. H. A comparison of laboratory determinations and Wetzel Grid estimates of basal metabolism among adolescents. *J. Pediat.*, 1955, **46**, 146-154. [Inst. Child Welfare, Univ. California, Berkeley.]

Metabolic and anthropometric measurements were made at intervals of about 6 months from 11.5 to 17.5 years of age in 52 boys and 52 girls. Cross-sectional measurements were made also on the control group for basal metabolism studies, 80 boys and 77 girls from 9.0 to 17.5 years old, of whom more than half were between 15 and 16 years old. The estimated basal metabolic rate

from the Wetzel grid was compared with the average of 6 measurements by the Tissot open-circuit technique, made on 2 consecutive days on each subject.

Of 522 measurements on boys and 475 on girls, 33 and 28 per cent. deviated from the grid estimate by at least 10 per cent. In the longitudinal study 22 of the 52 boys and 12 of the girls showed deviations of this order consistently, for one-third or more of their tests. The average difference from the grid estimate was 130 Cal. for boys and 100 Cal. for girls. In the control group the values were 125 and 107. In boys the grid estimates were consistently below the measured values and the difference increased with age, becoming significant at 12 years. In girls the grid underestimated B.M.R. at ages below 14 years and overestimated it thereafter, and the differences were significant except at 14.5 years, where the curves crossed.

Precautions to be taken in the use of grid estimates of B.M.R. are discussed.—D. Duncan.

3739

EICHORN, D. H. and MCKEE, J. P. Oral temperature and subcutaneous fat during adolescence. *Child Development*, 1953, **24**, 235-247. [Univ. California, Berkeley.]

Mouth temperature was recorded when B.M.R. measurements were being made and subcutaneous fat was measured on the anterior surface of the arm, on the abdomen and over the iliac crest. Fifty-three boys and 52 girls were examined at 6-month intervals from about 11 years of age. In boys the temperature declined steadily from 12½ to 17½ years of age, the relation being linear. In girls a rise occurred after 12½ and continued until 15 years; beyond that age there was a steady fall. At all ages above 13 years the girls' temperatures were higher than the boys'.

An attempt was made by correlation techniques to relate temperature to the amount of subcutaneous fat, to B.M.R. and to menarche in girls, but none of the relationships was clear and no single variable studied would account for the trends and sex differences in mouth temperature.

D. Harvey.

McKee, J. P. and Eichorn, D. H. **Seasonal variations in physiological functions during adolescence.** *Child Development*, 1953, **24**, 225-234. [Univ. California, Berkeley.]

The subjects were those described in the preceding Abst. Records were made on 2 successive days of B.M.R., respiratory and pulse rates, blood pressure and mouth temperature. The data were grouped according to months, regardless of the year, and corrections were applied for age and for individual differences. Mouth temperature in boys tended to rise in spring and decline in autumn. B.M.R. and pulse rate in both sexes declined in spring and rose in autumn. No seasonal variation was seen in respiratory rate or systolic pressure.

Passmore, R., Meiklejohn, A. P., Dewar, A. D. and Thow, R. K. **Energy utilization in overfed thin young men.** *Brit. J. Nutrition*, 1955, **9**, 20-27. [Dept. Physiol., Univ. Edinburgh.]

Three healthy but constitutionally thin young men resident in the metabolic ward of a hospital were given diets containing from 1300 to 1600 Cal. in excess of their requirements for 10 to 14 days. During this time a standard routine of physical activity was followed; oxygen consumption was measured at intervals of 4 hr. day and night and food samples, urine and faeces were collected for analysis.

During excess energy intake, daily energy expenditure rose by 85, 150 and 225 Cal. for the 3 subjects; protein intake rose from 79 to 131 g. daily for one subject and from 77 to 124 g. daily for the other 2. Metabolism reached basal levels by late evening and there was no evidence to suggest that the thinness of the men was due to any inherent ability to oxidise surplus food, apart from a small rise in metabolism attributable to the specific dynamic action of the extra protein ingested. From faecal analyses 90 per cent. of the excess food was shown to have been digested.

3742

Passmore, R., Meiklejohn, A. P., Dewar, A. D. and Thow, R. K. **An analysis of the gain in weight of overfed thin young men.** *Brit. J. Nutrition*, 1955, **9**, 27-37. [Dept. Physiol., Univ. Edinburgh.]

In the experiment described in the previous Abst. the balances of energy, N, water, Na and K were measured to investigate the nature of the material responsible for the weight gain which occurred. This gain was only about 70 per cent. of that expected for deposition of "obese tissue" of the composition 62 per cent. fat, 24 per cent. cell mass and 14 per cent. extracellular fluid as

described by Keys and Brožek (Title 624, Vol. 24). In the 3 subjects the weight gain was found to be entirely due to deposition of fat and protein; there was no evidence of gain of body water.

Terzioğlu, M. and Aykut, R. **Variations in basal metabolic rate at 1.85 km altitude.** *J. Appl. Physiol.*, 1954, **7**, 329-332. [Inst. Physiol., Univ. Istanbul.]

Estimations of B.M.R. were made on 12 subjects at sea level before their ascent to altitude 1.85 km. (6069 ft.), after residence there for 1 to 2, 5 to 6 and 10 to 11 days, and again at intervals after their descent. The average values in Cal. per 24 hr. per sq. m. per hr., respectively, were 7.4 and 7.6, 12.1 and 14.4, 13.6 and 16.0 per cent. above sea-level values at the end of the periods. After return to sea level the time taken for B.M.R. to return to pre-ascent value was 4 to 5 days for 5 subjects, 10 days for 2, 16 to 18 days for 4 and 33 days for 1 subject.

The findings contradict those of earlier workers, e.g., Liljestrand and Magnus, *Pflügers Arch.*, 1922, **193**, 527 and Loewy, *ibid.*, 1925, **207**, 632.

D. Harvey.

3744

Fraser, R. and Nordin, B. E. C. **The basal metabolic rate during sleep.** *Lancet*, 1955, **268**, 532-533. [Dept. Med., Post-grad. Med. Sch., London.]

The B.M.R. was estimated in 73 patients without sedation and then during sleep induced with intravenous pentobarbitone sodium, and in 53 patients during sleep induced with amylbarbitone sodium given by mouth.

In euthyroid patients the B.M.R. during sleep was in the normal range, or between 85 and 115 per cent. on the standard of Robertson and Reid (Abst. 2278, Vol. 22). In "nervous" patients the B.M.R. was above the normal range when they were awake, but fell to normal during sleep. The B.M.R. during sleep was high in thyrotoxic patients and low in myxoedema.

It is suggested that heavy sedation helps to reduce error associated with B.M.R. estimations for assessment of thyroid function.—D. Duncan.

3745

Vivanco, F. and Ramos, F. **Correlation between B.M.R. and protein-bound iodine in serum in normal subjects and in patients with thyroid disease.** *Bull. Inst. Med. Res., Univ. Madrid*, 1954, **7**, 63-68.

3746

De Langen, C. D. **Basal metabolism and sodium chloride.** *Acta med. scand.*, 1954, **150**, 257-261. [Utrecht.]

Basal metabolism estimated in 8 patients with Addison's disease ranged from -9 to -32 per cent. The administration of NaCl either by infusion or by mouth to 5 of the patients raised B.M.R. to normal, with a range of -2 to $+14$ per cent. The further addition of deoxycorticosterone acetate (DOCA) or cortisone had no appreciable effect. The B.M.R. of the other 3 patients rose to normal after administration of NaCl plus DOCA and remained normal after the withdrawal of DOCA except in one subject. A fall in B.M.R. followed the withdrawal of NaCl from 3 patients in balance with it.

Three normal subjects given a salt-free diet for 10 days had no change in B.M.R., but after Turkish baths for several days B.M.R. fell considerably. NaCl restored it to normal. NaCl is considered to affect oxygen consumption by its influence on capillary activity.—A. Hepburn.

PATRICK, R. M., RICHARDSON, P. S. and MOSCHETTE, D. S. Metabolic studies with pre-adolescent girls. 2. Energy absorption. *J. Amer. Dietetic Assoc.*, 1955, 31, 138-143. [Dept. Home Econ., Louisiana Agric. Exp. Stat., Baton Rouge.]

For part 1 see Abst. 4094, Vol. 25.

The subjects were 5 girls aged 8 and 9 and a girl aged 11 years whose diets were controlled for 56 days. Energy values of food and faeces were measured in the Emerson fuel calorimeter and for each subject data obtained in 8 periods are reported. Mean daily intake and mean daily absorption, in Cal. per kg. bodyweight, were 77.7 and 75.4, respectively. There was a direct relation between these values which was statistically highly significant. The percentage of energy absorbed by the 6 subjects was fairly constant, 96.6 to 97.8, mean 97.1.—F. C. Aitken.

DILL, D. B., SEED, J. C. and MARZULLI, F. N. Energy expenditure in bicycle riding. *J. Appl. Physiol.*, 1954, 7, 320-324. [Chem. Corps Med. Labs., Army Chem. Centre, Md.]

A comparison is made between bicycles with balloon tyres of American type of diameter $2\frac{1}{2}$ to $2\frac{3}{4}$ in., 22 to 28 lb. per sq. in. pressure, and those with narrow tyres of standard European type, of diameter $1\frac{1}{2}$ in., 50 to 60 lb. per sq. in. pressure. Experiments to measure the force required to hold the bicycle stationary on a treadmill at 15 m.p.h. showed that on level ground with the wind blowing from behind at the same rate as the bicycle it should be more than twice as easy to pedal the bicycle with narrow tyres as the one with balloon tyres. Road tests were made to compare the oxygen consumption required on each bicycle under the same conditions, and this was also found to be appreciably less for the narrow-tyred bicycle. It is concluded that for transport with minimum energy expenditure tyres of narrow diameter are preferable to balloon tyres.—I. McDonald.

SERAPHIN, R. Zur Frage der Wärmeregulation der Säuglinge und Frühgeborenen. [Heat regulation of infants and premature infants.] *Ztschr. Kinderheilk.*, 1955, 75, 664-670. [Kinderklin., Univ. Heidelberg.]

The temperature regulation of the inner surface of the hand was studied by means of a circulation calorimeter. The infants 6 to 10 weeks old were in a room temperature of 22° to 24° C., the pre-matures, 6 to 14 days old and weighing 1000 to 2000 g., at 27° to 29° C. A warm stimulus was obtained by an electric pad over the abdomen and legs, a cool one by directing a draught from a fan on to the head.

Vasomotor temperature regulation in these infants was quite as prompt and extensive as in adults. The so-called thermolability of infants is not due to lack of vasomotor regulation, but mainly to their unfavourable surface: volume ratio and other causes such as thin skin and fat insulation and lack of mobility.—D. Duncan.

ZÖLLNER, G., THAUER, R. and KAUFMANN, W. Der insensible Gewichtsverlust als Funktion der Umweltbedingungen. Die Abhängigkeit der Hautwasserabgabe von der Hauttemperatur bei verschiedenen Temperaturen und Wasserdampfdrücken der umgebenden Luft. [Insensible weight loss as a function of environment. Relation of water loss through the skin to skin temperature at different temperatures and vapour pressures of the surrounding

N.A. and R., July 1955

air.] *Pflügers Arch.*, 1955, **260**, 261-273. [William G. Kerkhoff-Just., Max-Planck-Gesellschaft., Bad Nauheim.]

Insensible weight loss and water loss through the skin were studied in 3 unclothed adults, 2 men and a woman, in 169 three-hour periods at different environmental temperatures and humidities. In the indifferent temperature zone and at constant relative humidity the insensible water loss and loss from the skin increased very gradually with rising body and skin temperatures, but after a critical body or skin temperature was reached the increase in water loss became steep, introducing a temperature-regulation mechanism.

Water loss through the skin fell with increasing relative humidity at constant skin temperature, and was a function of the saturation pressure at the skin temperature and the vapour pressure of the air.—D. Duncan.

DOBOS, F., HAMAR, N., PREDMERSZKY, T. and TARJÁN, S. Zahlenmäßige Kennzeichnung der Hitze-arbeitsverhältnisse in den Betrieben der Eisen- und Stahlindustrie mit einem "Hitze-arbeitsindex". Zusammenhang zwischen Hitze-arbeitsindex und dem Schwitzen des Hitzearbeiters. [Numerical characterisation of conditions of hot work in the workshops of the iron and steel industry with a "hot work index". Relation between the hot work index and sweating of workers in heat.] *Acta med. hung.*, 1954, **6**, 453-461. [Staatliches Inst. Arbeitshyg., Budapest.] Russian summary.

A "hot work index", which makes it possible to characterise by a single figure the conditions of working in heat, is computed from the amount of bodily work done at different periods of the day and from components of the surrounding atmospheric conditions, i.e., radiation, air temperature and humidity, air currents and the length of time the worker is exposed to these. The relation between the hot work index and loss of fluid by the worker in heat was estimated empirically and is represented graphically. The limits of its application are discussed. The hot work index appears to be suitable for characterising the working conditions in the iron and steel industries. From it numerous conclusions can be drawn about the average loss of fluid of workers engaged on different jobs.—M. B. Richards.

BEAKLEY, W. R. and FINDLAY, J. D. The effect of environmental temperature and humidity on the rectal temperature of calves. The effect of environmental temperature and humidity on the skin temperature of Ayrshire calves. The effect of environmental temperature and

humidity on the temperature of the skin of the scrotum in Ayrshire calves. The effect of environmental temperature and humidity on the ear temperatures of Ayrshire calves. *J. Agric. Sci.*, 1955, **45**, 339-352; 353-364; 365-372; 373-379. [Hannah Dairy Res. Inst., Kirkhill, Ayr.]

Rectal temperature of calves rose with increasing environmental temperatures from 15° to 40° C. and increasing humidity, the change from low to high humidity being equivalent to 4° C. at 30° C. environmental temperature and 9° C. at 35° C.

The skin temperatures of the calves at 8 sites on the trunk rose with increasing temperature, humidity and time of exposure. There was no difference between the sites in any one animal.

Skin temperatures of the scrotum behaved in general as those of the trunk. The difference between scrotal and rectal temperatures became less as environmental temperature increased.

Skin temperatures of the ears also behaved as those of the trunk, but were lower, and there was a critical environmental temperature between 15° and 20° C. at which a sudden increase in ear temperature took place.—T. D. Bell.

IRVING, L. and KROG, J. Temperature of skin in the Arctic as a regulator of heat. *J. Appl. Physiol.*, 1955, **7**, 355-364. [Arctic Health Res. Centre, Anchorage, Alaska.]

The skin beneath the fur or feathers of well adapted Arctic mammals or birds was not more than 10° C. colder than the body temperature, which varied little. Bare extremities such as the feet or nose were often near 0° C., but blood circulation was active. Cooling of the extremities serves for the dissipation of body heat. The sharp temperature gradients in the insulated parts of the extremities supported the view that heat is conserved by transfer from arterial to venous blood.

A. Hepburn.

3758

KROG, H., MONSON, M. and IRVING, L. Influence of cold upon the metabolism and body temperature of wild rats, albino rats and albino rats conditioned to cold. *J. Appl. Physiol.*, 1955, **7**, 349-354. [Arctic Health Res. Centre, Anchorage, Alaska.]

The first group, of 6 white rats, was kept in the warm room at 30° C. \pm 2 before the experiment, which began when the rats were 11 weeks old.

The second group consisted of 5 rats transferred at 4 weeks of age to a cold room at 20° C., and the temperature was reduced gradually to 5° C., at which level it remained for 6 weeks before the experiment. The third group was made up of 4 wild rats (*Rattus norvegicus*) captured in Alaska when the mean temperature was -23° C. and kept outside at the research station in a mean temperature of -14° C.

The respiratory quotient, measured at environmental temperatures between -40° and 30° C., showed no significant modification with temperature. The metabolic rate was higher in all groups at 20° than at 30°, and the critical temperature was calculated to be about 23°. The basal metabolic rate (B.M.R.) in white rats conditioned to cold was 60 per cent. above the empirical standard, but that of the other 2 groups did not differ significantly from the standard. The conditioned rats responded to cold by maintaining a metabolic rate consistently above that of white rats from the warm room. The former could withstand -30° for 2½ hr. before their metabolic rate declined, the latter only -10° for 2½ hr. The metabolic rate of wild rats rose in cold along the straight line which in conformity with Newton's law defines the metabolic maintenance of body temperature in animals adjusted to cold. At -40° the metabolic rate in some of this group was 6 times the B.M.R. The body temperatures of conditioned white rats did not fall appreciably after 2½ hr. at -10° C., but rats from the warm room could not maintain their body temperature in environments below 10°. No measurement was made on wild rats.

It is concluded that in domesticated white rats the metabolic response to cold is not as efficient as that in animals living naturally in a cold climate.
D. Duncan.

BARGETON, D., EON, M., KRUMM-HELLER, C., LIBERMANN, C. and MASSON, J. Influence de l'adaptation sur les réactions thermorégulatrices au froid chez le rat. [Effect of adaptation on heat-regulating reaction to cold in the rat.] *J. Physiol., Paris*, 1954, 46, 845-860. [Serv. Recherches, Soc. Theraplix, Paris.]

Rats kept out of doors from 4 days of age in the region of Paris in a mean winter temperature of 8.5° C. were compared with rats bred and main-

tained at 29.5 ± 0.5°. Their thermoregulation was studied under fasting conditions; after 20 hr. at thermal neutrality, 29.5 ± 0.5° C., they were exposed to cold at 20°, 15° and 10° for 35 min. and then returned to thermal neutrality.

The rats accustomed to cold showed some elevation of colon temperature at 10° C., produced less heat with a negligible decline, and controlled their heat loss more efficiently.—D. Duncan.

GARREN, H. W. and SHAFFNER, C. S. Factors concerned in the response of young New Hampshires to muscular fatigue. *Poultry Sci.*, 1954, 33, 1095-1104. [Poultry Dept., Univ. Maryland, College Park.]

Chicks about a month old were forced to exercise in a treadmill cage 3 ft. in circumference, turning at from 4 to 22 revolutions per min. Birds showed great variability in the time they would continue to exercise, and there was some evidence that those which continued longest had the heaviest adrenals. After 10 days of severe exercise chicks were killed; the mean weights of their hearts, pituitaries and adrenals were greater than those of non-exercised controls. In general males resisted exhaustion better than did females.

Supplementation of the diet of the chicks with 0.2 per cent. thiouracil for 2 weeks resulted in their becoming exhausted more rapidly. The use of 0.03 per cent. iodinated casein increased the resistance to fatigue of birds which had previously shown a poor performance in the cages.

A group that received an implant in the neck of 4 mg. testosterone showed a tendency to increased resistance after several periods of severe exercising. This effect was very variable, so that the range of performance in this group was even greater than in the controls.

Daily injections of either 2.5 or 5.0 mg. cortisone per kg. bodyweight had no significant effect on the resistance of the birds. The higher dose slightly depressed growth.—K. J. Carpenter.

BAKER, N., SHREEVE, W. W., SHIPLEY, R. A., INCEPY, G. E. and MILLER, M. **C¹⁴ studies in carbohydrate metabolism. 1. The oxidation of glucose in normal human subjects.** *J. Biol. Chem.*, 1954, **211**, 575-592. [Radioisotope Unit, Veterans Admin. Hosp., Cleveland, Ohio.]

From the specific activities of blood glucose and respiratory CO₂ in 4 normal subjects after a single injection of glucose uniformly labelled with ¹⁴C, the mean size of the glucose pool was calculated to be 0.15 g. per kg. bodyweight, distributed in a volume equivalent to 17 percent. of the bodyweight. The average turnover of the pool was 0.60 per cent. per min. The mean relative contribution of glucose to CO₂ was 21 per cent. and the amount of glucose oxidised accounted for about 60 per cent. of that removed from the pool in a given time. The change in specific activity of CO₂ after injection of labelled fructose, acetate and bicarbonate was compatible with the transfer of ¹⁴C from glucose to CO₂ through pools with rapid turnover.

HENNEMAN, D. H., ALTSCHULE, M. D. and GONCZ, R. M. **4. Effect of hydrocortisone and corticotropin (ACTH) on the metabolic effects of administered glucose in patients with chronic schizophrenic and manic-depressive psychoses.** *Arch. Int. Med.*, 1955, **95**, 241-246. [Lab. Clin. Physiol., McLean Hosp., Waverley, Mass.]

1. The 6 subjects with active multiple sclerosis were 38 to 56 years old and free of intercurrent disease; 4 were men. There were 20 normal controls of comparable age.

Fasting blood glucose, pyruvic acid and citric acid were normal, but lactic acid and α -ketoglutaric acid were high. After 100 g. glucose was taken by mouth there was a prolonged rise in blood glucose, excessive accumulation of lactic acid, and a rise, instead of the normal fall, in citric acid and α -ketoglutaric acid. The rise in citric acid was especially striking.

For part 2 see Abst. 2202, Vol. 25.

3. The methods and subjects were those described in part 2, but fructose was given by mouth or intravenously instead of glucose.

Vol. 25, No. 3

When fructose was given by mouth there was no significant difference in response between the psychotic patients and the normal controls, except a rise instead of a fall in blood glucose in the former. When the fructose was injected the chief difference was a rise in plasma citric acid in the patients, but not in the controls.

4. The subjects were 2 men and 2 women with chronic psychoses and a normal man. All had high-carbohydrate diets for 3 to 5 days before tests. In all subjects the glucose tolerance before and after administration of hydrocortisone or ACTH was within the normal range. The hormones produced in all 5 an increased rise in blood lactic acid after glucose administration; blood pyruvic acid behaved similarly in 2 of the patients. The normal subject showed after glucose alone or with hydrocortisone no change in blood citric acid; all 4 patients showed increases in blood citric acid after glucose in the control period, which changed to falls after hormones. In 2 of 3 patients blood α -ketoglutaric acid rose abnormally after glucose alone, but not after hormones. The third patient and the control showed high α -ketoglutaric acid levels only after hormones.

The changes observed in these 4 patients were typical of chronic psychoses in the control period, but after hormones the changes resembled those seen in psychoses of recent onset.—D. Duncan.

CHRISTOPHE, J. Détermination d'un coefficient d'assimilation glucidique chez le rat normal. Étude de l'influence de la dose de glucose sur l'assimilation. [Estimation of a glucose assimilation coefficient in the normal rat. Effect of the test dose of glucose on assimilation.] *C.R. Soc. Biol.*, 1955, **148**, 1886-1889. [Clin. Méd., Hôp. Brugmann, Univ. Brussels.]

Adult rats of the same strain and receiving a stock diet received after an 18-hr. fast a single intravenous injection of glucose. The dose per kg. bodyweight was 0.25 g. for 17 rats, 0.5 g. for 42 and 1.0 g. for 18, and the experiment was made under light nembutal narcosis.

The rate of assimilation of glucose was independent of the dose; it was quicker than in man and similar to that in the dog. A coefficient of assimilation is given.—D. Duncan.

3771

SCOW, R. O. and CORNFIELD, J. Quantitative relations between the oral and intravenous glucose tolerance curves. *Amer. J. Physiol.*, 1954, **179**, 435-438. [Lab. Biochem. Nutrit., Nat. Inst. Arthritis and Metabol. Dis., Bethesda, Md.]

Rats about 10 weeks old had oral and intravenous glucose tolerance tests, receiving 300 mg. glucose per 100 g. bodyweight by mouth or 125 mg. per 100 g. by vein. The rate of absorption of the same dose of glucose given by mouth was studied in other rats killed at different times after the meal.

The normal oral glucose tolerance curve could not be deduced only from knowledge of the rate of removal of glucose given by vein and the rate of intestinal absorption of glucose. The blood sugar values calculated from those rates exceed the actual values by a factor of 3, so glucose given by mouth must be removed considerably more quickly than glucose given by vein. If it is as-

sumed that only 37 per cent. of the glucose leaving the intestines enters the general circulation and 63 per cent. is removed by the liver, the calculated curve closely agrees with the actual curve. Glycogen formation in the liver, however, could not alone account for such an uptake of glucose.

D. Duncan.

3772

GARNER, R. J. and ROBERTS, R. The influence of previous diet on the fasting blood-sugar level and on glucose utilization in the rat and hamster. *Biochem. J.*, 1955, **59**, 224-228. [Vet. Lab., Univ. Bristol.]

After fasting for 17 hr., rats fed on a high-fat diet from weaning had lower blood glucose values at 7 and 10 weeks than similar animals on a control high-carbohydrate diet. By reversing the diets at 7 weeks the blood sugar of the fat-fed animals was restored to the control level at 10 weeks. Hamsters showed a fall in blood sugar with age, but, as with rats, the values at 7 and 10 weeks were lower on the high-fat than on the high-carbohydrate diet. Rats on the high-fat diet showed the reduced tolerance to intravenously injected glucose that has been recorded by others. Glucose uptake and glycogen synthesis by isolated rat diaphragm were both depressed when the carbohydrate intake was restricted by diets with excess fat or protein. The hexokinase activity of kidney homogenates from rats and hamsters was reduced by high-fat diets.—M. B. Richards.

ROY, S. N. and SADHU, D. P. On the mechanism of glycosuria in skim milk fed rats. *Indian J. Physiol. Allied Sci.*, 1954, **8**, 117-120. [Dept. Physiol. Animal Nutrit., Bengal Vet. Coll., Calcutta.]

One group of rats was given mineralised skimmed milk and pair-fed with another group given isocaloric whole milk. Galactose appeared in the urine of the skimmed milk group from the second day of experiment; when milk intake and

galactosuria were constant injections were given of enterogastrone, atropine sulphate, glucose, acid histamine phosphate or prostigmine. Liver and muscle glycogen, liver fat and blood and urine sugar were estimated.

Galactosuria was less after enterogastrone, atropine and glucose, and more after acid histamine phosphate and prostigmine. In the skimmed milk group there was a higher blood sugar, lower liver and muscle glycogen and liver neutral fat and higher liver phospholipin levels than in the group given whole milk. The mechanism of the galactosuria which occurs in rats on a skimmed milk diet is discussed.—G. F. Garton.

WICK, A. N., MORITA, T. N. and BARNET, H. N. Sorbitol metabolism in alloxan-diabetic animals as compared with fructose and glucose. *Food*

Res., 1955, 20, 66-70. [Scripps Metabol. Clin., La Jolla, Calif.]

About half the amount of radio-activity given as sorbitol or fructose uniformly labelled with ^{14}C was recovered as $^{14}\text{CO}_2$ from diabetic rats on a diet containing 68 per cent. sucrose; only 26 per cent. was recovered from glucose. With a diet containing 68 per cent. fructose, the oxidation of sorbitol was unaffected, but fructose was not oxidised better than glucose after 7 days. Rats given sorbitol excreted glucose in the urine. Rats given fructose excreted less than 5 per cent. of the carbohydrate as fructose. It is suggested that there are 2 oxidative pathways for sorbitol or fructose.—A. Hepburn.

DAUGHADAY, W. H., LARNER, J. and HARTNETT, C. The synthesis of inositol in the immature rat and chick embryo. *J. Biol. Chem.*, 1955, 212, 869-875. [Dept. Med., Sch. Med., Washington Univ., St. Louis, Mo.]

Radio-active inositol was isolated from the liver and carcass of immature rats after intraperitoneal injection of radio-active glucose. Activity was higher in rats with a low intake of inositol. Radio-active inositol was found in chick embryos after application of labelled glucose to the chorio-allantoic membrane.—A. Hepburn.

PEREIRA, M. D., HICKS, W. P., RILEY, J. D. and ELMAN, R. The effect on nitrogen balance of varying the proportion of infused protein hydrolysate and glucose. *Ann. Surg.*, 1954, 140, 349-353. [Surg. Metabol. Div., Homer G. Phillips Hosp., St. Louis, Mo.]

The subjects were 29 adults in hospital, 11 with advanced cancer and the others without acute disorders. Each received 2 litres of solution daily by intravenous injection for 7 days as sole source of food, with water as desired by mouth. The first and last 2 days were control periods when the solution was 10 per cent. glucose or fructose, and in the 3 experimental days a proportion of the sugar was replaced by amino-acids (Amigen) to provide the same energy intake, 800 Cal.

The highest positive N balance, 60 to 85 per cent. of that injected, was obtained when amino-acids provided 75 per cent. of the energy intake. In 7 subjects who received only amino-acids, without sugar, the N balance was from -3.7 to +3.1 g. daily, with a mean of -0.6 g.; in control periods on sugar alone the mean loss was 8.0 g. in

the first period and 7.3 g. in the second. Differences between subjects receiving glucose and fructose were not significant.

It is concluded that in malnourished patients with a low energy intake N retention increases as the proportion of protein given intravenously is increased from 25 to 75 per cent.—D. Duncan.

3781

CHRISTENSEN, H. N., WILBER, P. B., COYNE, B. A. and FISHER, J. H. Effects of simultaneous or prior infusion of sugars on the fate of infused protein hydrolysates. *J. Clin. Invest.*, 1955, **34**, 86-94. [Dept. Biochem. Nutrit., Med. Sch., Tufts Coll., Boston, Mass.]

Evidence is presented that there is wastage in the urine of free and bound amino-acids when commercial protein hydrolysates, autoclaved with 10 per cent. fructose or 5 or 10 per cent. glucose, are infused intravenously. Addition of the sugar to the hydrolysate immediately before infusion prevents peptide wastage, but not wastage of free amino-acids. Separate infusion of the sugar, which prevents amino-acid and peptide wastage, substantially reduces the immediate N catabolism.

NIKLAS, A. and POLIWODA, H. Zur Frage der biologischen Halbwertszeit menschlicher Albumine und Globuline. [Biological half-life of human albumin and globulin.] *Biochem. Ztschr.*, 1954, **326**, 97-106. [Med. Klin., Univ. Cologne.]

The curves of radio-activity in total serum and in its protein fractions were followed in 10 subjects, 9 normal and 1 with chronic nephritis, who each received a single injection of 20 or 30 μ g. methionine containing 200 μ C. of 35 S.

Total serum protein gave curves suggesting a half-life of 22 to 40 days. Albumin gave straight lines with half-life values of 55 to 65 days. Globulin did not give a straight line. From the curves it is calculated that new serum protein formation in the 9 normal subjects was about 9.2 ± 0.3 g. daily.—D. Duncan.

3783

RAMAMURTI, K. Studies on the nitrogen partition in the urine of Rajasthanis. *Indian J. Med. Res.*, 1955, **43**, 61-69. [Biochem. Lab., Birla Coll. Sci., Pilani, Rajasthan.]

The nitrogenous constituents were estimated in 24-hr. samples of urine from 24 Rajasthanis, 12 manual workers and 12 sedentary workers, living on typical low-N diets supplying 42.6 and 50.4 g. total protein daily. The average values for the 2 groups in g. were total N 5.2 and 10.9, urea 6.1 and 17.1, ammonia 0.37 and 0.48, uric acid 0.41 and 0.26, creatinine 0.81 and 1.23 and undeter-

mined N 1.30 and 1.81. Total N and urea were much lower than figures quoted for western standards, NH_3 , uric acid and creatinine were slightly less and undetermined N was appreciably higher.—A. Hepburn.

TRÉMOLIÈRES, J. and JACQUOT, R. Protéinogénèse et bilan azoté. [Protein formation and nitrogen balance.] *C.R. Acad. Sci.*, 1955, **240**, 235-236.

The increased excretion of N by the rat after treatment with cortisone is accompanied by a considerable increase in liver weight, of which about two-thirds is due to protein. The pregnant rat retains N, but in a quantity insufficient for growth of the foetus, whose demands are met from maternal tissue. These examples are taken to show that N balance is not a state of total catabolism or anabolism, but a summation of both.

CRAMPTON, E. W. and RUTHERFORD, B. E. Apparent digestibility of dietary protein as a function of protein level. *J. Nutrition*, 1954, **54**, 445-451. [Dept. Nutrit., Macdonald Coll., McGill Univ., Que.]

Rats were fed on diets consisting partly or entirely of whole egg powder or dry cheese with mineral and vitamin supplements, the balance being shredded wheat mixed with methyl cellulose. The apparent digestibility of the dietary protein

N.A. and R., July 1955

rose from about 65 per cent. when it was 6 per cent. of the diet to 95 per cent. when it was half the diet. Faecal protein per unit dry matter intake increased with increasing dietary protein; since a protein of low apparent digestibility was being replaced by a protein of high apparent digestibility the increase was not thought to be due to an increase in dietary protein residue, but rather to increased growth of alimentary microflora. It is postulated that the true digestibility of the proteins of egg, cheese and wheat is 100 per cent. and that differences in the apparent digestibility of protein foods are due to differences in the concentration of protein in them.—C. Warner.

SRINIVASAN, P. R. and PATWARDHAN, V. N. The effect of protein deficiency on (a) some liver constituents, and (b) enzymes in liver, pancreas and blood plasma in albino rats. *Indian J. Med. Res.*, 1955, 43, 1-13. [Nutrit. Res. Labs. Indian Counc. Med. Res., Coonoor.]

Groups of 30 rats, 15 of each sex, received from 3 months of age 3 different diets. The control diet contained 20 per cent. casein and the experimental diets contained 2 per cent. casein and 2 per cent. protein provided by 26 per cent. rice, respectively. Each diet contained 10 per cent. lard, 4 per cent. salt mixture and starch to 100 parts. Intake was restricted to 10 g. daily. Rats from each group were killed each month for 3 months, then the remaining protein-depleted rats were divided into 2 groups and continued on the low-protein diet or were given the control diet for another month. In a second experiment young rats, initially 21 to 28 days old, received the control or 2 per cent. casein diet for 1 month, then 12 deficient rats were killed and 6 were given the control diet for another month.

In adult rats liver fat showed a temporary increase after the second month of depletion, but there was no histological fatty infiltration. Glutathione fell in the first month and remained low. Succinic acid and butyric acid dehydrogenases were low from the first month onwards. Alkaline phosphatase activity rose progressively until the third month in adult rats. Acid phosphatase increased only after 3 months. Transaminase

activity fell in the first month, D-amino-acid oxidase and esterase in the second month. Oxygen consumption by liver slices fell in the first month and remained low. Re-alimentation restored all the liver constituents to normal.

Pancreatic lipase was reduced in the third month, especially on the rice diet. Plasma lipase was reduced only in the fourth month, when plasma esterase was also low.

In the young rats all the enzyme changes seen in adults in 3 months were already established after one month.—D. Duncan.

LUCAS, C. C. and RIDOUT, J. H. The lipotropic activity of protein. *Canad. J. Biochem. Physiol.*, 1955, 33, 25-30. [Banting and Best Dept. Med. Res., Univ. Toronto, Ont.]

Groups of 6 individually housed rats were fed to appetite on one of 4 diets for 3 weeks. The diets contained 3, 6, 9 and 18 per cent. vitamin-free casein; the total methionine content was kept uniform at 0.54 per cent. by addition of appropriate amounts of DL-methionine. The rest of the diet was made up with sucrose, salts, cellulose flour, maize oil and adequate amounts of vitamins; thus all diets contained equal amounts of choline and its known precursors. At the end of the experiment liver lipids were estimated.

More fat was found in the livers of the animals given the diets low in protein than in those on more adequate rations. It appears that protein exerts a lipotropic effect which does not directly involve choline or its known precursors. Histologically the fatty livers which were produced were different from those in choline deficiency.

KUZOVLEVA, O. B. Ob izmeneniyakh soderzhaniya aminokislot v pecheni belykh kry, nakhodyashchikhsya na diete, nedostatochnoi v otnoshenii belka. [Changes in free amino-acid content of the liver of white rats on a protein-deficient diet.] *Vop. Pitan.*, 1955, 14, No. 1, 30-34.

White rats of 120 to 160 g. were divided into 2 groups and given a normal mixed diet or an artificial diet containing 3 per cent. protein. The animals were killed after different periods and the amino-N of liver homogenates was estimated.

In normal rats, the average amino-N was 78.9 mg. per cent., but in deficient animals killed after 3 to 7, 9 to 15 and 24 to 52 days the values were 67.1, 73.2 and 85.9 mg. It is argued that, since on a protein-deficient diet liver protein falls and is accompanied at first by a fall and not a rise in amino-N, and since the protein content of other organs does not fall and may even rise, either amino-acids from breakdown of liver protein must

be at once utilised in the synthesis of protein for other tissues, or large quantities of amino-acid are not formed in the liver, re-synthesis of protein for other tissues taking place without preliminary complete splitting-up of liver protein.

HARADA, M. and HORIGUCHI, G. **Bone and nutrition (primary report). Experimental studies on changes of bone and bone-marrow in hypoproteinemia.** *Wakayama Med. Rep.*, 1954, 2, No. 1, 7-14. [Dept. Orthopaedic Surg., Wakayama Med. Sch.]

Rabbits received fresh vegetables, bean curd residues, and a basal or low-protein diet, the latter containing, per cent., starch 85.5, agar 5, sugar 5, butter 2, McCollum's salt mixture 2 and vitamin B complex components 0.5.

Five rabbits on the basal diet were subjected to plasmapheresis; 20 to 50 ml. blood was taken daily or every other day for 8 to 30 days. Body-weight and serum protein fell in proportion to the severity of plasmapheresis. All the rabbits showed thinning of epiphyseal cartilage and reduction of bone trabeculae, and 4 showed lacunar resorption of bone. There was reduction and hyaline degeneration of cartilage at the costochondral junctions.

Twelve rabbits received the low-protein diet, 30 or 40 g. daily for from 10 to 57 days. The bodyweight and serum protein fell for 2 weeks, but then remained fairly constant or fell slightly. The bone changes were similar to those seen in the first group but more pronounced.

The last 3 rabbits served as controls and received the basal diet for 14 to 28 days. Active bone formation was found at the end of the experiment.

It is suggested that bone formation is dependent on protein metabolism.—D. Duncan.

3793

KASAMATSU, S. **Histologische Untersuchungen des Kaninchen-Wurmfortsatzes unter einschiger Fütterung. [Histological experiments on the vermiform appendix of the rabbit during unbalanced feeding.]** *Wakayama Med. Rep.*, 1954, 2, No. 1, 35-42. [Anat. Inst., Med. Univ., Wakayama.]

In rabbits fed for 4 months on bean curd residues (*okara*) the wall of the appendix became thin, with great reduction in the amount of lymphoid tissue and changes in the epithelial cells, which are illustrated. The changes were not greater after 8 months than after 4. The changes were not prevented by supplements of carbohydrate, "vitamin powder" or injection of vitamins A and D. A supplement of coarse particles of filter paper, one part to 10 of diet, prevented the changes, but when half the diet was powdered filter paper the

appendix became thin. Once the wall had been affected by 4 months of *okara*, addition of coarse filter paper for another 4 months did not reverse the changes.

The results are considered to indicate a local effect of fibre on the structure of the appendix.

CAMPBELL, R. M., SHARP, G., BOYNE, A. W. and CUTHBERTSON, D. P. **Cortisone and the metabolic response to injury.** *Brit. J. Exp. Pathol.*, 1954, 35, 566-576. [Rowett Res. Inst., Bucksburn, Aberdeenshire.]

The excess urinary N excretion of rats after fracture of the femur was of magnitude similar to that after the implantation of a tablet containing 25 mg. cortisone acetate. Adrenalectomy with maintenance of the animals on 0.9 per cent. saline abolished the response to injury; adrenalectomy with maintenance on cortisone had little effect. Animals with low basal urinary N excretion responded more to trauma than those with high, especially when food intake was also low.

RUFF, J. J., PASCHKIS, K. E. and CANTAROW, A. **Role of potassium in the protein-catabolic effect of cortisone and ACTH.** *Endocrinology*, 1955, 56, 21-23. [Div. Endocrine Cancer Res., Jefferson Med. Coll., Philadelphia, Pa.]

The increased excretion of urinary N and the loss of weight caused by cortisone or adrenocorticotrophic hormone in rats was not altered by large doses of KCl.—A. Hepburn.

3796

KELEMEN, E., TANOS, B., HAJDU, L. and FORGÁCS, P. **Long-term suppression of a permeability response of the rat's hind-paw by cortisone, by hypophysectomy and by protein-deficient diet.** *Nature*, 1955, 175, 122-123. [I. Belgyógyászati Clin., Szeged, Hungary.]

Local injections of crude testicular extract containing hyaluronidase greatly increase the permeability of the rat's hind paw (Kelemen *et al.*, *Acta med. hung.*, 1951, 2, 201). Large doses of cortisone given subcutaneously suppressed the oedema thus produced; so did removal of the pituitary. In young rats maintained on a diet containing less than 2 per cent. protein the response disappeared, to return within 24 to 72 hr. after they were given a protein-rich diet.

It is suggested that one of the effects of a protein-deficient diet may be a shift of water into the extracellular compartment, with dehydration of connective tissues, and that cortisone and hypophysectomy also exert their influence on this phenomenon through changes in protein metabolism.—D. Duncan.

3797

GLASSER, S. R. Influence of an adequate dietary protein on the immediate and latent effects of stilbestrol. *Amer. J. Physiol.*, 1954, **179**, 421-428. [Bur. Biol. Res., Rutgers Univ., New Brunswick, N.J.]

Adult rats were given for 21 days a synthetic basal diet containing 18 per cent. casein with vitamin supplements; 0.1 mg. stilbestrol was injected daily into some and others were kept as pair-fed controls. At the end of the period both groups were divided equally; half of each group continued on the basal diet and half were given a similar diet without protein. Nitrogen balances were measured.

In both groups there was loss of weight, greater in the treated than in the untreated rats, and after injections were stopped the difference persisted on both the basal and the protein-free diet. Rats on the basal diet did gain weight, but those on the protein-free diet did not. The hormone caused an immediate increase in N excretion over that of the untreated rats but, by the twentieth day, both groups had recovered and were nearly in equilibrium. Continuation on the basal diet led to positive balances in both treated and untreated animals, greater in the former than in the latter; on the protein-free diet balances were negative.

In similar experiments the effect of vitamin B₁₂ on the influence of the hormone was studied, but none was found. Loss of liver weight occurred in groups with and without the hormone. Total protein in liver was greater in injected than in control animals, the difference resulting from differences in liver weight, not from differences in protein concentration. In recovery on the basal diet the groups did not differ and there was immediate restoration of N in liver; rats on the protein-free diet had less protein in their livers than had those on the basal diet.

The hormone had no immediate effect on liver fat. During recovery on the basal diet treated and untreated rats did not differ; those on the protein-free diet had more liver fat than did those recovering on the basal diet and the level in the treated was higher than in the untreated rats.

BEHM, G. Über den Einfluss der Rohfaser im Futter auf die Menge des Darmverlust-Stickstoffs, nach Versuchen an Ratten, Kaninchen und Schweinen. [Effect of crude fibre in feed on the faecal loss of nitrogen in experiments on rats, rabbits and pigs.] *Arch. Tierernährung*, 1954, **4**, 197-218. [Inst. Tierernähr., Humboldt Univ., Berlin.]

Rats, rabbits and pigs were fed on an N-free diet with different amounts of crude fibre in the

form of pure cellulose (shredded filter paper) or sawdust. In rats sawdust, but not cellulose, increased the faecal loss of N. With 5 per cent. or less of cellulose in the food, the faecal loss of N remained almost constant at 0.29 g. per 100 g. dry food. When the cellulose content rose to 20 per cent. the faecal loss of N fell to 0.22 g., with a change in the consistency of the faeces. With percentages of 10, 15 and 20 of sawdust in the feed, the faecal losses of N were respectively 0.27, 0.29 and 0.35 g. In rabbits, with a mixture of cellulose and sawdust no conclusion could be drawn about the faecal loss of N, but with sawdust alone, as in rats, the loss was increased. Experiments on pigs confirmed the reported value of 0.095 g. per 100 g. dry feed for faecal loss of N, provided the cellulose content of the feed did not exceed 5 per cent. With increase of cellulose the loss increased considerably, the values obtained for 5, 10 and 20 per cent. cellulose being 0.099, 0.129 and 0.199 g. Increasing amounts of sawdust acted in the same way, but the values reached for faecal loss of N were not so high as for the same amounts of cellulose.—M. B. Richards.

3799

ENGEL, R. W., LINKOUS, W. N. and BELL, W. B. Effect of protein on the toxicity of hexachloronaphthalene. *J. Nutrition*, 1955, **55**, 119-128. [Virginia Agric. Exp. Stat., Blacksburg.]

A total of 3 to 4 mg. hexachloronaphthalene given over 1 or 2 weeks produced liver enlargement with accumulation of fat in rats on a diet containing 9 per cent. casein. Significant protection against fat accumulation was achieved with 18 or 27 per cent. casein; liver fat increased much more gradually than in the rats on the 9 per cent. casein diet.—A. Hepburn.

SCHREIER, K. Some peculiarities of amino acid metabolism in infancy and early childhood. *J. Pediat.*, 1955, **46**, 86-106. [Kinderklin., Univ. Heidelberg.]

A review.

3802

DUSTIN, J. P., MOORE, S. and BIGWOOD, E. J. **Chromatographic studies on the excretion of amino acids in early infancy.** *Metabolism*, 1955, 4, 75-79. [Lab. Biochem., Fac. Med., Univ. Brussels.]

Urine from a premature infant at 38 days and 18 weeks old, a 25-day-old normal infant and an adult were analysed for amino-acids by ion exchange chromatography. Expressed as a percentage of total urinary N, the total values were 4.3 and 3.6, 2.9 and 1.1. Threonine, glycine, serine plus asparagine plus glutamine (not separated), alanine, cystine, glutamic acid and proline were very much higher in infant than in adult urine. The first 3 and tyrosine were much higher in the premature than in the normal infant. Basic amino-acids were excreted at about the same rate in the two infants and the adult.

ROSE, W. C., LAMBERT, G. F. and COON, M. J. **The amino acid requirements of man. 7. General procedures; the tryptophan requirement.**

ROSE, W. C., COON, M. J., LAMBERT, G. F. and HOWE, E. E. **8. The metabolic availability of the optical isomers of acetyltryptophan.** *J. Biol. Chem.*, 1954, 211, 815-827; 1955, 212, 201-205. [Div. Biochem., Noyes Lab. Chem., Univ. Illinois, Urbana.]

For part 6 see Abst. 2224, Vol. 25.

7. With purified diets containing the known essential amino-acids, glycine and sometimes urea, and in which just over 1 per cent. of the N was of unknown origin, the amount of L-tryptophan needed to maintain N balance in young men was studied.

In 3 experiments, accurately measured, it was 0.15, 0.15 and 0.25 g. daily; in 15 it was less than 0.20 g. daily. No correlation was found between the tryptophan requirements of the subjects and their bodyweights, surface areas or creatinine outputs. Little, if any, of the D-isomer was utilised. It is suggested that 0.50 g. tryptophan daily is a safe intake.—C. Warner.

8. N balance experiments with young men showed that acetyl-D-tryptophan, like free D-tryptophan, was not utilised significantly. Acetylation did not reduce the availability of L-tryptophan or increase that of DL-tryptophan.

SUMIYOSHI, T. [Experimental studies on the skeletal growth, especially on the changes of the epiphyseal cartilage of albino rats receiving amino-acid deficient diet. 2. Influence of corn diet on the skeletal growth, especially on the epiphyseal cartilage. 3. Influence of lysine deficient diet on the skeletal growth, especially on the epiphyseal cartilage.] *Shikoku Acta Med.*, 1954, 5, No. 4, 60-71; 72-81. [Dept. Int. Med., Sch. Med., Tokushima Univ.] In Japanese: English summary.

2. Sixteen rats were given 3 diets in which maize flour was the sole source of protein; for 14 others there were 3 similar diets with wheat flour, casein and dried milk, wheat flour and casein, or casein and starch replacing the maize flour. All diets contained salt and vitamin mixtures. The experiments lasted for from 21 to 191 days.

Among those receiving the maize flour diets growth was slower and long bones were shorter than in corresponding control rats. These changes were greater in male than in female rats. In the epiphyseal cartilages in which closure normally occurs by the age of 6 months ossification was later in the experimental than in the control group. In the cartilages which normally ossify later in life ossification did not occur but [presumably in the experimental group] there was impaired osteogenic activity or a retardation of normal ageing. In further experiments with rats on restricted feeding with the control diet these changes were not reproduced.

3. A diet without lysine consisted of, per cent., starch 58, lard 5, simsim oil 10, vitamin mixture 2, salt mixture 5, the remaining 20 per cent. being a mixture of 9 essential amino-acids; a control diet had the same proportions of lard, simsim oil and vitamin and salt mixtures, 25 per cent. casein and 53 per cent. starch. These diets were given to comparable rats, and a third set were restricted to an amount of the control diet maintaining the same rate of growth as in the lysine-deficient rats.

In the experimental animals there was atrophy of the epiphyseal cartilage and epiphyseal growth ceased; the changes were more severe in lysine-deficient than in restricted rats. They confirmed that, of the amino-acids, lysine is essential for skeletal growth.—D. Harvey.

SHILS, M. E. and STEWART, W. B. **Preventive influence of certain amino acids on experimental fatty liver of portal type.** *Proc. Soc. Exp. Biol. Med.*, 1954, **87**, 629-631. [Sch. Pub. Health, Coll. Phys. Surg., Columbia Univ., New York.]

Rats given a diet with 74 per cent. vegetable protein, either maize meal, white rice or cassava flour, developed a portal type of fatty liver which was partly or completely prevented by lysine or tryptophan. Methionine and threonine had little or no additional effect, but threonine produced a gain in weight in the rats fed on rice.

CAVALLINI, D. and TENTORI, L. **Aminoaciduria da arginina. [Amino-aciduria produced by arginine.]** *Rend. Ist. Super. Sanità, Rome*, 1954, **17**, 85-87. [Ist. Clin. Biol., Univ. Rome.] French, English and German summaries.

The method was the same as that described in Abst. 3331, Vol. 24.

In rats on normal diet the urine gave 3 ninhydrin-positive spots, identified as glutamic acid, glycine and alanine. Administration of arginine increased the number of such spots to 11, the extra amino-acids being aspartic acid, glutamine, arginine, lysine, γ -aminobutyric acid, valine, leucine and tyrosine. Not all these amino-acids can be considered as metabolites of arginine. Fewer amino-acids appeared after ornithine or glutamic acid was given.—D. Duncan.

ROTHSTEIN, M. and MILLER, L. L. **The conversion of lysine to pipecolic acid in the rat.** *J. Biol.*

Vol. 25, No. 3

Chem., 1954, **211**, 851-858. [Dept. Radiat. Biol., Sch. Med. Dent., Univ. Rochester, N.Y.]

When rats were injected with L-lysine-6- 14 C and L-pipecolic acid, the pipecolic acid isolated from the urine was strongly radio-active. When 15 N-labelled lysine was used, the pipecolic acid in the urine acquired the label of the ϵ - but not of the α -N. With L- α -aminoadipic acid the label of the α -N of lysine was taken up, the α -N giving a slight enrichment thought to be due to transamination. It is suggested that lysine is deaminated to ϵ -amino- α -ketocaproic acid, followed by cyclisation and reduction to form pipecolic acid, which is then converted to α -aminoadipic acid.

When 14 C-labelled aminoadipic acid was injected with pipecolic acid, no radio-activity was found in the pipecolic acid isolated, and it is suggested that the conversion of pipecolic acid to aminoadipic acid was irreversible.—C. Warner.

3811

BOTHWELL, J. W., PRIGMORE, J. R. and WILLIAMS, J. N. (Jr.) **A study of the nitrogen metabolism of lysine-deficient rats.** *J. Nutrition*, 1954, **54**, 469-478. [Dept. Biochem., Univ. Wisconsin, Madison.]

Weanling rats forcibly fed on a lysine-deficient diet remained in positive N balance until death (see Abst. 609, Vol. 23). In a similar experiment urinary N was found to be increased, mainly owing to increased urea concentration, but blood N remained normal despite a slight increase in blood urea. The continued positive N balance was therefore not due to kidney damage and retention of N in the blood.—C. Warner.

HABERLAND, G. L., BRUNS, F. and ALTMAN, K. I. **Ein neuer Stoffwechselweg von Phenylalanin und verwandten Substanzen im Organismus der Ratte. Ein Beitrag zur endogenen Entstehung der Benzoesäure. [New metabolic pathway of phenylalanine and related substances in the rat organism. Endogenous origin of benzoic acid.]** *Biochem. Ztschr.*, 1954, **326**, 107-109. [Biochem. Lab., Div. Exp. Radiol., Dept. Radiol., Univ. Rochester, N.Y.]

The excretion of hippuric acid and the relative isotope concentration in rats was studied after intraperitoneal injection of 3-6 mg. carboxyl- 14 C-benzoic acid and 500 mg. phenylalanine or a related substance. Injection of phenylserine caused a significant increase in hippuric acid excretion and a fall in the relative isotope concentration. Phenylalanine and phenylpyruvic acid caused no increase in hippuric acid excretion, but a distinct fall of the relative isotope concentration, showing that these substances also must be regarded as forerunners of benzoic acid formed endogenously.

It is conceivable that these compounds are broken down to benzaldehyde and then oxidised to benzoic acid by an aldehyde oxidase. Tyrosine and tryptophan were without effect. When 3-¹⁴C-DL-phenylalanine was injected intraperitoneally into rats, a relatively large part of the ¹⁴C activity, after separation by paper chromatography, was found in the hippuric acid spot.—M. B. Richards.

VENNART, G. P. and MCKEE, F. W. **The role of homocystine in protecting protein-depleted dogs exposed to fatal doses of chloroform.** *J. Exp. Med.*, 1955, **101**, 197-204. [Dept. Pathol., Sch. Med. Dent., Univ. Rochester, N.Y.]

Adult dogs which had had their protein reserves depleted by diet and bleeding in several weeks to 4.0 to 5.0 g. per cent. were protected from the lethal action of chloroform by 2 g. homocystine given by mouth either 2 hr. before or 2 hr. after anaesthesia. Without the protection of homocystine there was a constant post-anaesthesia fall in fibrinogen and rise in the icteric index, and death occurred in 30 to 48 hr., with severe central liver necrosis. In the protected animals changes in fibrinogen and icteric indices were not constant. No evidence was obtained that methyl groups are necessary for the protection of the liver by homocystine.

SCHWEIGERT, B. S. and GUTHNECK, B. T. **Utilization of amino acids from foods by the rat. 3. Methionine.** *J. Nutrition*, 1954, **54**, 333-343. [Div. Biochem. Nutrit., Amer. Meat Inst. Found., Chicago, Ill.]

Weanling or protein-depleted adult rats were fed on a basal ration deficient in methionine, in which most of the N came from casein treated with H₂O₂ and formic acid. Supplements of 13 methionine-containing foods were compared with L-methionine for their capacity to support weight gain. In most tests the results with weanling and adult rats were similar, but the methionine of soya bean products, sesame meal and pork ham was better utilised by the weanling rats, and that of beef rib was better utilised by the adult depleted rats. The methionine of unheated soya bean flakes was only 44 per cent. as efficient as pure L-methionine for supporting weight gain; other figures were lactalbumin 52 per cent., skimmed milk, wheat germ, rolled oats, split peas, sesame meal, pork luncheon meat and beef rib between 60 and 70, soya bean meal, soya bean grits, pork ham, canned pork and beef and beef rib between 70 and 80, and casein 83 per cent. Only part of the inefficiency of these foodstuffs was due to increased excretion of methionine in the faeces; the sum of the percentage

of ingested methionine excreted and the percentage utilised for weight gain varied from 55 per cent. for lactalbumin to 89 per cent. for rolled oats. There was no difference between DL- and L-methionine in capacity to support weight gain.

WILLIAMSON, M. B. and FROMM, H. J. **Excretion of sulfur during healing of experimental wounds.** *Proc. Soc. Exp. Biol. Med.*, 1954, **87**, 366-368. [Dept. Biochem., Sch. Med., Loyola Univ., Chicago, Ill.]

Female rats weighing 200 ± 20 g. were given for 5 days a protein-free diet containing, per cent., sucrose 83, lard 10, maize oil 2 and salt mixture 5, with a vitamin supplement. They received 8 g. daily. Wounds were then made in the backs of experimental rats but not of controls. Faeces and urine were collected thereafter.

In 30 wounded rats kept on the basal diet N excretion for 2 weeks was greater than that of unwounded controls. Total S excretion was about the same in both groups, but wounded rats excreted about 40 per cent. more sulphate S, which may mean that their metabolism of sulphur amino-acids was increased.

When wounded and unwounded rats after 4 days on the basal diet received ³⁵S-cystine by intraperitoneal injection they excreted more ³⁵S than rats which similarly received ³⁵S-methionine. After both labelled amino-acids the wounded rats excreted more ³⁵S as sulphate than did controls.

WILLIAMSON, M. B. and FROMM, H. J. **The incorporation of sulfur amino acids into the proteins of regenerating wound tissue.** *J. Biol. Chem.*, 1955, **212**, 705-712. [Dept. Biochem., Stritch Sch. Med., Loyola Univ., Chicago, Ill.]

The protein hydrolysates of regenerating wound tissue in rats contained more sulphur amino-acids than normal tissue. The methionine content was

N.A. and R., July 1955

greater than that of cysteine plus cystine at first, but this was soon reversed. Two proteins were therefore considered to be synthesised. Injection of ^{35}S -cysteine after wounding resulted in rapid uptake and loss of activity in wound tissue, skin, muscle and liver. As the amount of cysteine plus cystine in the tissues remained constant the decrease of activity was attributed to protein turnover and label dilution. Liver methionine decreased considerably.

Methionine and cysteine plus cystine were separated and their activities were estimated in the tissues after the injection of labelled methionine. The activity of methionine decreased in the wound tissue, but the activity of cysteine plus cystine remained almost constant, owing presumably to transfer of label from methionine. The uptake and loss of labelled methionine and cystine by the livers of wounded rats were significantly greater than in normal rats. An increased rate of S metabolism during wound regeneration is evident, and liver methionine supplies a large part of the cystine required.—A. Hepburn.

REGISTER, U. D. and BARTLETT, R. G. (Jr.) **Effect of cold and restraint on tissue non-protein sulphydryl compounds in methionine-deficient rats.** *J. Biol. Chem.*, 1955, **212**, 741-745. [Dept. Biochem., Sch. Med., Coll. Med. Evangelists, Loma Linda, Calif.]

Rats deficient in methionine and exposed to cold in cages which restricted movement had increased amounts of non-protein sulphydryl compounds in the liver, but in non-deficient rats similarly exposed these compounds decreased. Both groups of rats had decreased amounts in the kidneys. Deficiency of methionine increased amounts of sulphydryl compounds in the blood, but cold and restraint did not affect them. Adrenaline produced changes in the liver and kidney similar to those caused by exposure to cold and restraint.—A. Hepburn.

LEVY, H. M., MONTAÑEZ, G. and DUNN, M. S. **Effect of ethionine and fasting on the free amino acids of rat liver.** *J. Biol. Chem.*, 1955, **212**, 985-990. [Chem. Lab., Univ. California, Los Angeles.]

The concentrations of methionine, glycine, lysine, aspartic acid and glutamic acid in the livers of fasted rats increased after injection of 200 mg. DL-ethionine. Serine decreased. Similar trends were obtained in fed rats given 100 mg. ethionine, but the increases in lysine, aspartic acid and glutamic acid were larger and occurred sooner; lysine and methionine fell and serine increased after 16 hr.—A. Hepburn.

ORD, M. G. and STOCKEN, L. A. **Creatine and carbohydrate metabolism.** *Biochem. J.*, 1955, **59**, 272-279. [Dept. Biochem., Univ. Oxford.]

In guineapigs the creatine content of the liver, which was less than 12 mg. per 100 g. liver in the fed animal, rose to 2 or 3 times as much within 24 hr. after withdrawal of food, with a proportional rise in phosphocreatine. In rats also there was a rise, though a smaller one, in liver creatine, but urinary creatine was much increased, while blood glucose fell to 60 or 70 mg. per 100 ml. Tissue analyses did not reveal the origin of the creatine, but perfusion experiments showed a reversible dependence of muscle creatine on the blood glucose level. The relation between creatine distribution, carbohydrate metabolism and electrolyte balance is discussed.—M. B. Richards.

BENEDICT, J. D., KALINSKY, H. J., SCARRONE, L. A., WERTHEIM, A. R. and STETTEN, DEW. (Jr.) **The origin of urinary creatine in progressive muscular dystrophy.** *J. Clin. Invest.*, 1955, **34**, 141-145. [Div. Nutrit. Physiol., Pub. Health Res. Inst. City of New York, Inc.]

The study described in Abst. 2348, Vol. 22 was extended to 2 more subjects with progressive muscular dystrophy. They were maintained on a creatine-free diet low in purines and each received by mouth 100 mg. glycine labelled with ^{15}N per kg. bodyweight. They later received several intravenous injections of sodium benzoate. Urine was collected for 14 days.

Initially urinary creatine contained much more ^{15}N than did creatinine, but by the eighth or tenth day the isotope level in the creatine had fallen to about that in the creatinine. The results are taken as confirmation that the urinary creatine did not leak out of muscle, but was newly formed in the liver and not taken up by the muscle. The isotope concentrations in creatinine were higher than those found earlier in normal subjects, though creatinine output was less.

At all times there was 2 or 3 times as much ^{15}N in the sarcosine moiety of creatine as in the hippurate. The significance of this is discussed.

PAL, R. K. and MITRA, B. N. **Studies in uric acid metabolism.** *Indian J. Physiol. Allied Sci.*,

1954, 8, 89-97. [Dept. Physiol., R.G. Kar Med. Coll., Calcutta.]

The average uric acid content of blood from dogs was 0.45 and 0.65 mg. per 100 ml., on low- and high-purine diets, respectively. Tea or coffee produced an initial increase in uric acid, but the level then fell despite further doses. Tea or coffee given with a fish and chapati diet which alone had no effect gave a persistent increase in blood uric acid.

When the diet contained the large fish rohu (*Labeo rohita*) there was normal blood uric acid, but with the small fish puti (*Barbus ticto*), tenger (*Mystus carasius*) and khalse (*Colisa fasciatus*), uric acid was doubled after 3 days.

When the blood uric acid was raised by injection of uric acid the concentration of allantoin in the urine gradually fell. Blood was seen in some stools and 2 deaths occurred. Post-mortem examination showed haemorrhage in the digestive tract. These effects could be reversed and more normal levels of uric acid and allantoin restored by administration of colchicum, salicylates or cinchophen.

MANNING, P. R. and WALFORD, R. L. Lack of effect of fat ingestion on blood coagulation. *Amer. J. Med. Sci.*, 1954, 228, 652-655. [Med. Serv., U.S. Air Force Hosp., Chanute Air Force Base, Ill.]

Lipæmia was induced in 3 groups each of 4 patients, by administration of 240 ml. of 12, 20 and 40 per cent. cream, respectively, corresponding to 29, 48 and 96 g. fat. A meal of butter, bacon and egg containing 85 g. fat was given to 18 patients. After 1, 2, 3 and 4 hr. blood samples were taken for study of clot retraction, coagulation time and prothrombin consumption.

No statistically significant difference was found in any of the blood properties under examination.

KARSTEN, G. and BECKER, M. Versuche mit langfristiger fettfreier Ernährung an Wiederkäuern. [Experiments in prolonged feeding of ruminants on a fat-free diet.] *Arch. Tierernährung*, 1954, No. 5, Beihefte, 95-102. [Inst. Tierernährung, Völknerode, Brunswick.]

The aim of the experiments was to estimate the amount of endogenous fat excreted in the faeces. Three nearly fullgrown wethers were kept for 5 to 6 months on a diet almost without fat. The feeds used, hay, potato flakes and soya bean meal, were extracted in a specially constructed giant Soxhlet apparatus, first with methanol and then with trichloroethylene, and freed from solvent in a vacuum drying cupboard at 100° C. The extracted

mixed feed contained less than 0.1 per cent. ether extract. Vitamins A, D, E, K and choline in pure form were added.

The feed was not palatable and molasses did not improve palatability, but salt (NaCl) solution did. It was continued for 162 days without sign of deficiency and, at the end, weight, structure and quality of wool were normal. Three metabolism studies were made at intervals. With a daily intake of 0.697 g. crude fat, of which 0.174 g. was unsaponifiable matter and 0.328 g. fatty acids, saturated and lower unsaturated, average excretion was usually 2 to 3 g. crude fat, occasionally only 1 to 2 g. Of this 20 to 45 per cent. was unsaponifiable matter, the rest mostly saturated fatty acids with a little oleic acid.

At the end of the experiment, the sheep were slaughtered and fat was estimated in stomach and intestinal contents, and in samples of body fat, with special reference to highly unsaturated fatty acids. The rumen contents had a fat content 10 times that of the feed and of similar composition; higher unsaturated acids were not found. The high content is attributed to "mechanical accumulation". Synthesis of linoleic acid is not probable, and the linoleic acid content of depot fat had fallen almost to zero. The lipids of organs and especially hair, on the other hand, still had considerable amounts of highly unsaturated fatty acids.—I. Leitch.

PANOS, T. C. and FINERTY, J. C. Effects of fat-free diet on growing male rats with special reference to the endocrine system. *J. Nutrition*, 1954, 54, 315-331. [Dept. Paediat., Univ. Texas Med. Branch, Galveston.]

Twenty male rats were given from weaning a diet of Purina chow; 35 similar rats were given a fat-free diet of vitamin-free casein 18, sucrose 76, salts 4 and cellulose 2 per cent. with added vitamins

N.A. and R., July 1955

A, D₂, E and those of the B group. After 20 weeks during which weight gains and oxygen consumption were measured at intervals, the animals were killed and organs were removed for macroscopic and microscopic examination. Two other groups of rats were given identical treatment in a study of organ : bodyweight ratios after 2 and 5 weeks, respectively, on the fat-free diet.

In all rats given the fat-free diet growth was impaired, bodyweight being only 66 per cent. of that of controls. Typical skin lesions on tail, feet and back began to appear after 9 weeks on the deficient diet and oxygen consumption increased as early as 2 weeks. On a bodyweight basis the brain, adrenals, liver, heart and kidneys were significantly heavier than in the controls, but the thyroid was smaller. Microscopic studies showed intertubular accumulations of blood in the kidneys and thickening of the epidermis as found previously (Abst. 4834, Vol. 23) in female rats, and accumulation of fatty droplets round hepatic veins. There was increased vascularity of the myocardium. Non-relative weight changes of the testes, prostate and seminal vesicles were not significant, but the seminiferous tubules of all fat-deficient rats showed signs of degeneration, intercellular and intracellular vacuolation and reduction of spermatids and mature spermatozoa. The rats given the fat-free diet for 2 or 5 weeks showed similar differences from controls in bodyweight and weight of brain, liver, heart, kidney and thyroid.—G. F. Garton.

NARAYANA RAO, M. **The relationship of glyceride structure to fat digestibility.** *Indian J. Med. Res.*, 1955, **43**, 51–56. [Food Technol. Lab., Indian Inst. Sci., Bangalore 3.]

Groups of 6 individually-caged adult rats were fed to appetite for 10 to 12 days on diets which contained 10 per cent. coconut oil, groundnut oil or butterfat or glyceride fractions of these oils prepared by low-temperature crystallisation from acetone. The rest of the diet consisted of casein 12, maize starch 60, sucrose 10, "vitaminised" starch 4 and salts 4 per cent. During the last 6 days food consumption was recorded and the faeces were collected for analysis.

All the oils and their glyceride fractions, which varied in I value from 2.7 to 122.0, were almost completely digested. All the fats had melting-points above 50° C. The I value and saponification value of the faecal lipids of the rats were almost the same and had similar fatty acid composition. G. A. Garton.

3830

NORCIA, L. N. and LUNDBERG, W. O. **Fat excretion. The influence of dietary fat on fecal fat**

Vol. 25, No. 3

excretion. *J. Nutrition*, 1954, **54**, 491–508. [Dept. Physiol. Chem., Univ. Minnesota, Minneapolis.]

Two groups of rats were fed on diets containing 15 per cent. olive oil or tripalmitin for 30 days. The 2 groups of animals were then divided into sub-groups, each of which was given one of 4 test diets for 10 days; during the last 7 days faeces were collected. The test diets contained tripalmitin, triolein, a mixture of tripalmitin and trilinolenin, or no fat.

Faecal fat was unaffected in quantity or composition by any of the dietary fats used. Although the depot fats varied considerably in composition (see next Abst.) they did not influence the composition of the endogenous faecal fat. The results therefore support the view that endogenous faecal fat is of bacterial origin.—G. A. Garton.

3831

NORCIA, L. N. and LUNDBERG, W. O. **Body fat deposition. The influence of lard, olive oil and some simple triglycerides on rat body fats.** *J. Nutrition*, 1954, **54**, 509–522. [Dept. Physiol. Chem., Univ. Minnesota, Minneapolis.]

Groups of rats were fed on the diets described (see preceding Abst.); when they were killed total fatty acids, unsaponifiable matter, neutralisation equivalent, I value, peroxide value and fatty acid composition were estimated in body fat.

The diet containing tripalmitin as the only source of fat caused depletion of body fat reserves and reduced the I value of body fat, which was attributable to decrease of di- and tetra-ethenoid fatty acids and increase of monoethenoid unsaturation. All the body fats of animals fed on the olive oil diet and then on that containing tripalmitin and trilinolenin showed an increase in diethenoid fatty acid. Similar increases in diethenoid fatty acid were found in the perirenal and mesenteric depot fats of the animals which received the diet containing tripalmitin and trilinolenin after the conditioning diet containing tripalmitin. The liver fat of these animals showed a substantial increase in tetraethenoid fatty acids when trilinolenin was included in the diet.—G. A. Garton.

3832

AAES-JØRGENSEN, E., ENGEL, P. F., FUNCH, J. P. and DAM, H. **The role of fat in the diet of rats. 7. The influence on growth of diets supplemented with raw skim milk, linoleic acid or both; and of raw casein compared with alcohol-extracted casein.** *Brit. J. Nutrition*, 1955, **9**, 42–49. [Dept. Biochem. Nutrit., Polytech. Inst. Copenhagen.]

For previous work in this series see Abst. 806, Vol. 25 and Aaes-Jørgensen, "The role of fat in the diet of rats. 6. Influence of various fats in

ordinary refined state and after hydrogenation or polymerisation" (Copenhagen, Store Nordiske Videnskabsboghhandel, 1954).

Twenty groups, each of 6 weanling female rats, were given food and drinking fluid to appetite for 26 weeks. Growth, energy and fluid intake and urine output were measured and histological studies were made of the kidneys. The basic diet contained lard 28, sucrose 46, casein (crude or alcohol-extracted) 20, McCollum's salt mixture 5 and vitamin mixture 1 per cent. For different groups hydrogenated groundnut oil was substituted for lard or fat was omitted, raw skimmed milk was given as drinking fluid and the diets were supplemented with 20 or 100 mg. linoleic acid per rat daily.

With diets containing 28 per cent. hydrogenated groundnut oil growth was improved by substitution of crude for alcohol-extracted casein, or of skimmed milk for water, or by supplementation with linoleic acid, which gave the greatest effect. The effects of linoleic acid and of skimmed milk appeared to be additive. With diets containing 28 per cent. lard, growth was again increased by crude casein or skimmed milk.

Growth of the rats receiving 28 per cent. hydrogenated groundnut oil and water to drink was significantly slower than that of rats given a fat-free diet and water; when skimmed milk was given instead of water, growth on both diets improved, though the fat-free diet was still better.

Calculi in the cortico-medullary border of the kidneys were more numerous in rats which had been fed on diets containing 28 per cent. lard than in those which had received 28 per cent. hydrogenated groundnut oil.—G. A. Garton.

3833

DEUEL, H. J. (Jr.), ALFON-SLATER, R. B., WELLS, A. F., KRYDER, G. D. and ARTERGOOD, L. The effect of fat level of the diet on general nutrition. 14. Further studies of the effect of hydrogenated coconut oil on essential fatty acid deficiency in the rat. *J. Nutrition*, 1955, 55, 337-346. [Dept. Biochem. Nutrit., Sch. Med., Univ. S. California, Los Angeles.]

For previous parts see Absts. 2277, 2278, Vol. 25.

Weanling rats were fed on otherwise fat-free diets containing 5, 15 or 30 per cent. of hydrogenated coconut oil or none, until signs of essential fatty acid deficiency were apparent, i.e., failure of weight increase and lesions of the tail skin. Animals which had received 30 per cent. hydrogenated coconut oil were then given a daily supplement of 20, 40 or 80 mg. linoleate or none for 8 weeks and the effects on growth rate and recovery from the fatty acid deficiency were studied. At the end of the experiment free and total cholesterol were estimated in extracts of plasma and livers. Three

groups of weanling rats were fed on a fat-free diet, a diet containing 15 per cent. cottonseed oil and one containing 15 per cent. hydrogenated coconut oil. Animals in all groups were killed at intervals of up to 13 weeks for estimation of free and total cholesterol in plasma and liver.

The addition of hydrogenated coconut oil to an otherwise fat-free diet resulted in more rapid depletion of essential fatty acids than in animals on the fat-free diet alone. The subsequent response to linoleate was not impaired by the continued intake of hydrogenated oil. The diets without linoleate produced also an increase in liver cholesterol and a fall in plasma cholesterol. When diets containing hydrogenated coconut oil were continued with added linoleate, there was a return to normal of liver and plasma cholesterol, possibly owing to the availability of short-chain fatty acids contained in the hydrogenated oil for esterification of cholesterol.—G. A. Garton.

ERSHOFF, B. H. and GREENBERG, S. M. Comparative effects of dietary fat and dextrin on mineral oil toxicity in the mouse. *Amer. J. Digest. Dis.*, 1954, 21, 363-365. [Dept. Biochem. Nutrit., Univ. S. California, Los Angeles.]

Groups of young mice were fed to appetite on a low-fat diet supplemented with mineral oil at 5, 7.5 and 10 per cent. The 2 higher proportions resulted in retardation of growth and development of alopecia. When the diet containing 7.5 per cent. mineral oil was supplemented with 10 per cent. cottonseed oil or hydrogenated coconut oil, the rate of growth was improved, but alopecia was not completely prevented. When white dextrin, containing 0.6 per cent. bound fat, was substituted for glucose in the low-fat ration, both the growth-retarding effect of mineral oil and the attendant alopecia were prevented. It is therefore suggested that the effects of mineral oil cannot be wholly due to deficiency of essential fatty acids.

REISER, R. and DIECKERT, J. W. The influence of dietary fat on the glyceride structure of animal fat. *J. Amer. Oil Chem. Soc.*, 1954, 31, 625-628. [Dept. Biochem. Nutrit., Texas Agric. Exp. Stat., Texas Agric. and Mech. Coll. System, College Station.]

Groups of rats and chickens were reared on an almost fat-free basal diet. Body fat was then isolated from these animals and given at the 20 per cent. level with the same basal diet to other groups of rats and chickens; still other groups were given similar diets containing 20 per cent. cottonseed oil, and a fourth lot of chickens was given the same basal diet with 10 per cent. cottonseed oil. After several weeks on these diets the

animals were killed and their carcase fats were extracted and analysed for oleic, linoleic and linolenic acids and for saturated triglycerides.

Fat produced endogenously by the rat is formed with a random distribution of fatty acids, and in this species ingested fat appears to be digested and re-synthesised in a manner which tends to distribute the fatty acids selectively; thus, after ingestion of rat fat or cottonseed oil the percentage of saturated triglycerides in body fat was only 75 to 80 per cent. of that which would be expected from a random distribution of the component fatty acids of the dietary fat.

The results with chickens differed from those obtained with rats. After the diets containing 20 per cent. chicken fat or 10 per cent. cottonseed oil, the amounts of saturated triglycerides in the carcase fats were 150 per cent. greater than would have been expected from a random redistribution of ingested fatty acids; 235 per cent. more saturated triglycerides were found after the diet containing 20 per cent. cottonseed oil.

Possible mechanisms to explain these different observations in the 2 species are discussed, among others the higher body temperature of the chicken.

THOMAS, K., WEITZEL, G., SCHÖN, H. and GEY, F.
Beziehungen zwischen Fettsäuren mittlerer Kettenlänge und Hautfett. [Relation between fatty acids of medium chain length and skin fat.] *Arch. Tierernährung*, 1954, No. 5, Beihefte, 103-109. [Med. Forschungsanst., Max Planck Gesellsch., Göttingen.]

For 21 days 10 young rats of 60 to 80 g. body-weight received a normal diet, 5 rats a diet containing 37 per cent. lard and 10 rats a similar diet with 37 per cent. mixed glycerides of C_8 , C_{10} and C_{12} fatty acids. The last diet increased the saponification number and decreased the iodine number of cutaneous and subcutaneous fat. The steam-volatile fatty acid content of 10 g. skin fat was 100 mg. on the normal diet, 150 mg. after lard and 450 mg. after glyceride diet.

In a second similar experiment 5 rats received a normal diet and 3 groups of 10 received the same with 10 per cent., respectively, of C_8 or C_{10} triglycerides or C_{16} ethyl ester. In all 3 experimental groups the amounts of skin fat and subcutaneous fat after 21 days considerably exceeded those of controls, and this was so especially in the C_{16} group. The C_{10} group showed significant increases in the saponification number of fat from both sources; the C_8 group a smaller increase in the skin fat only, and both C_{10} and C_{16} groups had reduced iodine numbers. The steam-volatile fatty acids per 10 g. skin fat rose from 100 mg. on normal diet to 610 mg. with C_8 triglycerides, to 760 mg.

Vol. 25, No. 3

with C_{10} , but only to 180 mg. with C_{16} ethyl ester. The corresponding values for subcutaneous fat were 90, 160, 770 and 140 mg.

It is concluded that the subcutaneous fat can store up fatty acids from C_{10} upwards, but little C_8 acid, while the skin can accumulate significant amounts of C_8 acids.—D. Duncan.

GROSSMAN, M. I., PALM, L., BECKER, G. H. and MOELLER, H. C. Effect of lipemia and heparin on free fatty acid content of rat plasma. *Proc. Soc. Exp. Biol. Med.*, 1954, 87, 312-315. [Med. Nutrit. Lab., Fitzsimons Army Hosp., Denver, Colo.]

Heparin was injected intravenously into rats, some of which were fasting; others had been given maize oil by stomach tube. Blood was withdrawn at intervals and free fatty acid was estimated by the method of Davis (Abst. 73, Vol. 18).

The injection of heparin produced a moderate increase in the free fatty acid content of the plasma of fasting animals and a greater increase in those with free blood fat; in the latter a definite decrease in the total fatty acid content of plasma was found. In rats not given heparin, but with free blood fat, a moderate rise in plasma free fatty acid values was found.—G. A. Garton.

3838

GARNER, R. J. and ROBERTS, R. Effect of acetate on the fasting blood-sugar level of the rat. *Nature*, 1954, 174, 1194-1195. [Vet. Lab., Univ. Bristol.]

Rats were fasted for 17 hr. and then anaesthetised with Nembutal. Blood samples were taken by heart puncture before and 30, 60, 120 and 180 min. after intraperitoneal injection of sodium acetate, 100 or 200 mg. per 100 g. bodyweight, or the same amount of Na as saline. The acetate produced a transient rise of blood sugar, without a subsequent fall.

Weanling rats tolerated acetate in the diet at levels up to 13 per cent., but at higher levels growth was depressed. Acetate at 13 per cent. of the diet had no effect on the blood sugar estimated after a 17-hr. fast.—D. Duncan.

3839

WEINMAN, E. O., LOSSOW, W. J., CHAIKOFF, I. L. and DAUBEN, W. G. Conversion of 15th carbon of palmitic acid to CO_2 by the intact rat. *Proc. Soc. Exp. Biol. Med.*, 1954, 87, 414-417. [Dept. Physiol., Sch. Med., Univ. California, Berkeley.]

Fasting rats received an intravenous injection of 1 ml. of an emulsion containing tripalmitin- ^{14}C 2, olive oil 2, glycerylmonostearate 1, glucose 5, and water 90 per cent. Respiratory CO_2 was

collected continuously for 24 hr., during which time 16 separate samples were taken for estimation of the $^{14}\text{CO}_2$ content.

The amounts of $^{14}\text{CO}_2$ expired and the specific activity-time relations of the $^{14}\text{CO}_2$ corresponded closely with results obtained earlier (Weinman *et al.*, *J. Biol. Chem.*, 1950, **184**, 735) with tripalmitin- ^{14}C , tripalmitin-6- ^{14}C and tripalmitin-11- ^{14}C . On the average 66 per cent. of the injected ^{14}C was expired as $^{14}\text{CO}_2$. The present findings support the postulate that all the C atoms of palmitic acid are converted to CO_2 at almost identical rates.

G. A. Garton.

COLWELL, A. R. (Jr.) **Occurrence of accumulation of fat in the liver and its relation to excess weight gain in patients convalescing from viral hepatitis.** *Ann. Int. Med.*, 1954, **41**, 963-979. [U.S. Army Hosp., Kyoto, Japan.]

In biopsy material from 144 soldiers with infective hepatitis an accumulation of liver fat was found in about half, in whom the disease was in the sub-acute, 6 weeks' duration, or in the chronic, 13 weeks' duration, phases; none was seen in the early acute phase. In patients in both of those phases the gain of bodyweight was more than twice that in patients without liver fat. Liver function as measured by the bromosulphalein test was not impaired. The fat deposition is attributed to diets high in energy, protein and fat while the patients were relatively inactive. Vitamin B_{12} had no lipotropic effect.—D. Harvey.

3841

ARATA, D., HARPER, A. E., SVENNEBY, G., WILLIAMS, J. N. (Jr.) and ELVEHJEM, C. A. **Some effects of dietary threonine, tryptophan, and choline on liver enzymes and fat.** *Proc. Soc. Exp. Biol. Med.*, 1954, **87**, 544-549. [Dept. Biochem., Coll. Agric., Univ. Wisconsin, Madison.]

A basal diet including 9 per cent. casein, choline, methionine, and tryptophan produced deposition of liver fat in rats. The addition of threonine reduced liver fat and increased endogenous oxidation and carboxylation and the activity of the soluble enzymes xanthine oxidase and tyrosine oxidase in liver homogenates. The activity of the mitochondrial enzyme systems choline oxidase, succinic oxidase and pyruvic oxidase appeared to vary inversely with the rate of endogenous oxidation. Both threonine and tryptophan were necessary for growth. When choline was omitted threonine increased endogenous oxidation and carboxylation and the activity of the 2 soluble enzymes, but did not reduce liver fat. When tryptophan was omitted threonine reduced liver fat, but did not affect endogenous metabolism or enzyme activities.

It was concluded that the accumulation of liver fat was not associated with the change in enzyme activity.—A. Hepburn.

3842

BUCKLEY, G. F. and HARTROFT, W. S. **Pathology of choline deficiency in the mouse: observations with special reference to liver.** *Arch. Pathol.*, 1955, **59**, 185-197. [Banting and Best Dept. Med. Res., Univ. Toronto.]

Ninety mice were fed from 3 weeks old on a choline-deficient basal diet, but half received 0.5 per cent. choline chloride. Animals were killed after from 3 to 25 weeks for histological study of the liver. Another 20 mice given the same diets at weaning were killed after from 2 to 24 days.

In choline-deficient mice the livers became much enlarged, but "hobnail liver" was never seen. Surface irregularity was due to fatty cysts below the capsule. The lobules were easily seen because they were distended with fat. Even after 2 days of deficiency there was stainable fat in nearly every parenchymal cell, and the deposits rapidly increased. A fatty cyst was seen as early as the eighth day in one mouse, and cysts were present in all by the end of a month. They became as large as $150\ \mu$, or more in diameter. Fibrosis was never appreciable. Ruptured cysts were rare. Bile-duct hyperplasia was seen from the 24th day onwards, and was accompanied by adenomatous change in 11 of the 51 choline-deficient animals. Ceroid deposits were common. The kidneys often contained stainable fat deposits in the proximal convoluted tubules.

The lesions are compared with those seen in rats.—D. Duncan.

3843

LACHAZE, A. and LÉVY, M. **Influence du froid sur la stéatose hépatique produite par des régimes hypoprotéiques-hyperlipidiques. Variations de l'oxydase des acides gras dans le foie. [Effect of cold on fatty liver produced by low-protein, high-fat diets. Variations in fatty acid oxidase of the liver.]** *Arch. Sci. physiol.*, 1955, **9**, 63-70. [Lab. Physiol. Gén., Sorbonne.]

Groups of rats were fed for 14 days on a diet of lard 40, sucrose 48, casein 5, agar 2 and salts 5 per cent., supplemented with vitamins A, D and those of the B group. Control animals received a diet of lard 10, sucrose 58, casein 25, agar 2 and salts 5 per cent., with the same vitamin supplement. The rats were housed at environmental temperatures of 5° , 12° or 24°C . At the end of the experiment the animals were killed and their livers were removed for estimation of total lipids and fatty acid oxidase activity. The experiments were repeated with thyroidectomised rats housed at 12° and 24°C .

Deposition of fat in the liver was much less at 5° than at 12° or 24° C. The fatty acid oxidase activity of the livers of the animals on the high-fat diet at 5° C. was slightly less than that in the rats similarly housed at 5° C. but given a normal diet. The activity of the livers of animals given the high-fat diets at 12° and 24° C. was very low compared with the oxidase activity of the livers of rats given the normal diet, or there was none. Under similar conditions, the amount of fat deposited and the reduction of fatty acid oxidase activity in thyroidectomized rats given the high-fat diet were less than in normal rats.—G. A. Garton.

3844

FENTON, P. F., DOWLING, M. T. and MERSHON, J. S. Relation of dietary fat level to fatty livers in several strains of mice. *J. Nat. Cancer Inst.*, 1954, 15, 429-432. [Dept. Biol., Brown Univ., Providence, R.I.]

Groups of weanling male mice of 5 strains were fed for 4 to 7 months on a high-fat diet containing maize oil 5 and Crisco 45 per cent., or for 8 to 17 months on a stock diet containing about 5 per cent. fat. When the animals were killed total body fat and liver fat and liver choline oxidase were studied.

The mice of 4 of the strains developed fatty livers on the diet with 50 per cent. fat; this was due neither to low liver choline oxidase activity nor to deficiency of choline. One strain of mice could not be made obese and did not develop fatty livers.—G. A. Garton.

BARATTA, P. F., ANGELI, G., LUSIANI, G. B. and CAVAZZUTI, F. Azione dell'eparina sulla steatosi epatica da dieta iperlipidica-ipoproteica. [Effect of heparin on fatty liver induced with a diet high in fat and low in protein.] Azione dell'eparina sulla steatosi epatica da dieta ipercolesterolica. [Effect of heparin on fatty

Vol. 25, No. 3

liver induced with a diet high in cholesterol.] *Bol. Soc. ital. Biol. sper.*, 1954, 30, 161-164; 164-166. [Ist. Clin. Med., Univ. Modena.]

Of 20 rats maintained on a complete diet with 42 per cent. fat and 7 per cent. casein 10 were given an intraperitoneal injection of 2.5 mg. heparin every other day. After 18 days, all were killed and fat in the liver was estimated. For those not given heparin, the mean fat content, in g. per 100 g. fresh liver, was 9.98, range 7.10 to 18.00, and for those given heparin 6.71, range 5.30 to 7.50. The value for normal rats ranged from 4.76 to 5.75.

Twenty-seven rats were maintained on a stock diet to which 4 per cent. cholesterol had been added; 2 groups of 8 received in addition an intraperitoneal injection of heparin every 3 days for 15 or 25 days. At the end of the experiment fat was estimated in the liver as before. The mean fat content, in g. per 100 g. fresh liver, for those given and not given heparin, respectively, was after 15 days, 6.55, range 5.75 to 8.25, and 9.05, range 7.50 to 11.50, and after 25 days, 9.59, range 6.25 to 14.25, and 14.12, range 10.00 to 18.50.

CLÉMENT, J. Variations des teneurs en esters phosphoriques accompagnant les phosphatides du foie et du sérum de rat sous l'influence de divers régimes déséquilibrés. [Variations in the phosphoric esters accompanying the phosphatides of the liver and serum of the rat as affected by different unbalanced diets.] *Arch. Sci. physiol.*, 1955, 9, 51-61. [Lab. Physiol., Inst. Recherches Cancer, C.N.R.S., Paris.]

The basal diet, A, contained, per 100 g., casein 17, lactalbumin 3, lard 10, salts 5, agar 2.5, yeast 2.5, sucrose 55 and cholesterol 5 g., with all the known vitamins and 0.2 per cent. choline. Modifications were: diet B contained also 0.6 per 1000 of butter yellow; C, 0.6 per 1000 butter yellow, no choline; D, no cholesterol, no choline; E, 20 per cent. lard, 30 per cent. sucrose, 15 per cent.

lactose, no choline, no cholesterol, 0.6 per 1000 butter yellow. Groups of 40 rats received the first 4 diets from the age of 2 months; a fifth group received diet E when they were 6 months old. Analyses were made of liver and blood after from 7 to 22 months.

In control rats on stock diet there was no phosphoric ester P in the liver phosphatide fraction. Diet A produced fatty livers in which phosphoric esters accounted for from 18.4 to 26.2 per cent. of the total phosphatide P. In diet B the butter yellow produced no tumour even after 2 years, but it reduced the amount of fat stored, and the phosphoric ester was 8.6 to 16 per cent. Diet C produced after 6 or 7 months much deposition of lipid, and P distribution in 3 rats killed at that time was variable. Tumours appeared in survivors after 9 to 12 months and the fat then disappeared. In tumour-free liver tissue phosphatide P was low and phosphoric ester P varied from 0 to 41 per cent. The hepatoma was rich in ester P. With diet D there was no tumour, little or no fat deposition, and ester P varied from 4 to 17 per cent. Diet E gave results similar to those with diet C.

In the 2 groups which developed tumours, C and E, there was a considerable rise in total lipid P in the serum, but no phosphoric ester P.

D. Duncan.

3849

REISER, R. and DIECKERT, J. W. **Synthesis of mucosa and lymph phospholipide during fat absorption.** *Proc. Soc. Exp. Biol. Med.*, 1954, **87**, 622-626. [Dept. Biochem. Nutrit., Texas Agric. Exp. Stat., Agric. and Mech. Coll. System, College Station.]

Fasting rats were given either trilinolein labelled with ^{14}C in the α - and α^1 -positions of the glycerol and containing conjugated linoleic acid, or tripalmitin labelled with ^{14}C in both the α -position of the glycerol and the carboxyl group of the fatty acid. The triglycerides were incorporated in a fat-free basal mixture and the animals were killed 3 hr. after the test meal. The small intestines were removed, washed and extracted with ethanol-ether. Phospholipins were prepared from the extract and the component fatty acids were examined spectrophotometrically for conjugated linoleic acid or assayed for ^{14}C activity.

From a consideration of the results obtained and those reported earlier (Abst. 863, Vol. 22) it is concluded that, in the rat, phospholipins of the intestinal mucosa and lymph are derived from re-synthesised triglycerides.—G. A. Garton.

3850

HELLMAN, L., ROSENFELD, R. S., ELDINOFF, M. L., FUKUSHIMA, D. K., GALLACHER, T. F., WANG,

C. I. and ADLERSBERG, D. **Isotopic studies of plasma cholesterol of endogenous and exogenous origins.** *J. Clin. Invest.*, 1955, **34**, 48-60. [Div. Phys., Sloan-Kettering Inst. Cancer Res., New York.]

Cholesterol labelled with ^{14}C or tritium was given by mouth to subjects with normal and high plasma sterol values and its incorporation into plasma cholesterol was studied for a long time. Endogenous and exogenous cholesterol metabolism were studied in some instances by administration of isotopically-labelled acetate and cholesterol.

From 4 to 27 per cent. of a 10-mg. dose of cholesterol appeared in the plasma; 14 to 43 per cent. was recovered from the faeces during the first 4 days and about 1 per cent. appeared in the urine. Traces were found in the plasma within 1 hr. and the radio-activity of free and ester cholesterol was maximum after 2 to 3 days. In contrast, labelled plasma cholesterol formed from acetate showed its maximum specific activity within 8 hr. No difference in the pattern of incorporation was found in 2 patients with raised plasma cholesterol associated with *xanthoma tendinosum*, though differences in the proportions of free and ester cholesterol were found in subjects with high blood cholesterol associated with *xanthoma tuberosum* and nephrosis.

It is concluded that dietary cholesterol mixes indistinguishably with cholesterol formed in the body.—G. A. Garton.

3851

FROBLICH, A. L., WACHSMUTH, H., BUYSSENS, N. and VAN KOEKHOVEN, L. **Les altérations du métabolisme des phosphatides et des stéroïdes au cours de l'anémie pernicieuse. [Changes in the metabolism of phosphatides and sterols in pernicious anaemia.]** *Acta gastro-enterol. belg.*, 1954, **17**, 761-775. [Lab. Biochim., Inst. Bunge, Antwerp.] Dutch, English, German, and Spanish summaries.

In 10 patients with pernicious anaemia the total blood fat was low, from 292 to 740 mg. per 100 ml., mainly because of low levels of phospholipins and cholesterol. The phospholipin content was related to the red cell count. Free cholesterol was at the lower limit of normal, but esterified cholesterol was usually about half the normal amount. Cholesterolase activity in serum was normal.

All the subjects responded with the reticulocyte crisis after parenteral administration of 30 μg . vitamin B_{12} . The blood cholesterol began to rise slowly after the reticulocyte response, and reached a peak between the 30th and 45th days after treatment, then gradually returned to normal. The phospholipin level rose much more rapidly before the end of the reticulocyte crisis, and reached its

maximum in the fourth or fifth week, when the red cell count became normal. The neutral fat varied irregularly, but when the red cell count became normal it was usually somewhat lower than before treatment.

Bile obtained by duodenal intubation from 8 patients with pernicious anaemia was low in choline and bile acids and sometimes in cholesterol also. All these responded after treatment with vitamin B₁₂. Liver biopsies revealed no steatosis during anaemia, though haemosiderin and lipofuchsin were constantly found. Post-mortem examination of tissues from 2 patients showed normal phospholipin and lecithin contents.—D. Duncan.

3852

BLOCH, K., CLARK, L. C. and HARARY, I. Utilization of branched chain acids in cholesterol synthesis. *J. Biol. Chem.*, 1954, **211**, 687-699. [Dept. Biochem., Univ. Chicago, Ill.]

The branched-chain acids 3-¹⁴C- β -hydroxy- β -methylglutaric acid, 3-¹⁴C-*cis*- β -methylglutaconic acid, 3-¹⁴C- β -hydroxyisovaleric acid and 3-¹⁴C- β -dimethylacrylic acid were given to rats. Cholesterol and fatty acids were subsequently isolated from the livers of the animals for study of their radioactivity. Cholesterol from liver and other organs was also partly degraded for estimation of ¹⁴C concentration in carbon atoms 10 and 25.

The branched-chain acids were converted to cholesterol without first being metabolised to acetate or acetoacetate. In experiments with liver homogenates limited conversion of branched-chain acids to cholesterol was found.

G. A. Garton.

3853

FRIEDMAN, M. and BYERS, S. O. (with OMOTO, C., HAYASHI, W. and GUNNING, B.) Pathogenesis of dietary-induced hypercholesteremia in the rabbit. *Amer. J. Physiol.*, 1954, **179**, 201-215. [Harold Brunn Inst., Mount Zion Hosp., San Francisco, Calif.]

The rate of cholesterol formation, the rate of intestinal absorption and excretion of cholesterol and the rate of its disappearance from plasma were studied with many groups of rabbits, in which high plasma values of cholesterol can readily be induced by high-cholesterol diet, and rats, in which high values of plasma cholesterol cannot be similarly induced.

It was concluded that the species difference was primarily due to a much slower clearance of absorbed dietary cholesterol from the plasma in the rabbit, because the hepatic reticulo-endothelial system is slower to remove cholesterol-containing chylomicrons. In addition, rabbits absorbed a greater proportion of dietary cholesterol than did rats.—G. A. Garton.

HEPTINSTALL, R. H. and BRONTE-STEWART, B. Visceral and plasma changes in cholesterol-fed rabbits with raised blood-pressure. *J. Pathol. Bacteriol.*, 1954, **68**, 395-405. [Dept. Pathol., St. Mary's Hosp., London.]

Groups of rabbits, 11 and 9 in number, in which blood pressure was raised after nephrectomy, were given Bruce and Parkes' diet 18 (Abst. 3677, Vol. 16) with between 0.5 and 0.6 g. added cholesterol daily or without; 12 and 16 normal rabbits were given the same diet. Total plasma cholesterol was estimated at 2-week intervals and most of the rabbits were killed after 72 days; 1 from each group was killed after only 35 days and 1 retained for 100 days. The pathological changes were studied.

In rabbits given no cholesterol its level in plasma did not increase; in most of those given cholesterol its level in plasma rose, but operative treatment had no effect on the level reached. The ratio of adrenal weight to carcase weight was higher in those given cholesterol, but hypertension was without effect. The ratio of heart weight to carcase weight was greater in those with hypertension, but cholesterol was without effect.

BRONTE-STEWART, B. and HEPTINSTALL, R. H. The relationship between experimental hypertension and cholesterol-induced atheroma in rabbits. *J. Pathol. Bacteriol.*, 1954, **68**, 407-417. [Med. Unit, St. Mary's Hosp., London.]

The rabbits with hypertension were those mentioned in the preceding Abst. The findings after cholesterol feeding for 72 days in terms of range of blood pressure, number of rabbits and extent of atheroma as average percentage of aorta involved, were: 80 to 89, 5, 12.8; 90 to 99, 5, 15.1; 100 to 109, 4, 61.2, and 110 and over, 3, 50.3. There was some indication that cholesterol caused a slight but significant rise in blood pressure in both treated and normal rabbits.—D. Harvey.

3856

CHAKRAVARTY, R. N., DEY, U. N. and MUKERJI, B. Preliminary observation on experimental cholesterol atherosclerosis in rabbits with special reference to the reticular structure of the arterial wall. *Indian J. Med. Res.*, 1955, **43**, 79-87. [Central Drug Res. Inst., Lucknow.]

Groups of rabbits were fed on a stock diet containing gram, bran and fresh vegetables supplemented with 5 ml. cottonseed oil or 5 ml. cottonseed oil containing from 0.5 mg. to 1.0 g. cholesterol per head daily. After about 3 weeks

the cholesterol-fed animals began to show proliferation of the reticular connective tissue of the aortic intima and pulmonary artery, followed by deposition of esterified cholesterol. Atheromatous changes were found in one animal given cottonseed oil alone.—G. A. Garton.

3857

LOEWE, L., GOLDNER, M. G., RAPOPORT, S. M. and STERN, I. Failure of protein to protect against cholesterol atherogenesis in underfed rabbits. *Proc. Soc. Exp. Biol. Med.*, 1954, **87**, 360-362. [Jacques Loewe Res. Found. Labs., Jewish Hosp., Brooklyn, N.Y.]

One group of adult rabbits was given a restricted diet containing 35 per cent. protein and supplementary choline and methionine, the other group an isocaloric diet containing 16 per cent. protein. The animals were given also 2 g. cholesterol daily for 9 weeks. At intervals blood samples were analysed for total cholesterol, phospholipids, fatty acids and lipoproteins. Finally the animals were killed and the aortas were examined for arteriosclerotic lesions.

Marked atherosclerosis and increased concentrations of blood lipids and lipoproteins were found in all animals.—G. A. Garton.

3858

GOLDBERG, L. and SMITH, J. P. The influence of aureomycin on the response of the rabbit to cholesterol feeding. *J. Pathol. Bacteriol.*, 1954, **68**, 475-493. [Dept. Pathol., Univ. Manchester.]

Aureomycin and cholesterol, alone or in combination, were added to 2 basal diets given to adult rabbits. One was low in fat, the other had cottonseed oil in final concentration of 12.4 per cent. In the low-fat experiments the doses of cholesterol and aureomycin were 500 and 25 mg., respectively, per kg. bodyweight daily. In the high-fat experiments cholesterol was given as 1.4 per cent. of the diet and aureomycin at the same rate as in the low-fat experiments. Feeding continued for 8 weeks.

The rabbits given aureomycin alone or the low-fat diet with cholesterol and aureomycin lost weight; control animals, those on the high-fat diet with aureomycin and cholesterol or cholesterol alone and those on the low-fat diet with cholesterol maintained their weight. On the low-fat diet the incidence and severity of liver cirrhosis were lower in the group given both aureomycin and cholesterol than in that given cholesterol alone; on the high-fat diet with these same additions the incidence was similar in the 2 groups. On both low- and high-fat diets aureomycin reduced the total lipid content of liver.

Histologically 2 types of cirrhosis are described. In the first, found in 15 of 18 rabbits given the low-fat diet with cholesterol and in only 3 of 11 given the same treatment with aureomycin in addition, there was an increase in reticulin and collagen fibres without gross structural alteration other than fatty change; in the second, fibrosis occurred generally round deformed liver cells laden with fat and cholesterol and on its incidence aureomycin had no beneficial effect.

It is suggested that the effects of aureomycin may result from its action on tissue enzymes.

LINDSAY, S., NICHOLS, C. W. (Jr.) and CHAIKOFF, I. L. Aortic lesions induced in the bird by diethylstilbestrol injections and cholesterol feeding: a study of their development and regression. *Arch. Pathol.*, 1955, **59**, 173-184. [Dept. Pathol., Univ. California Sch. Med., San Francisco.]

Cockerels in 3 groups were fed on Purina broiler chow with 5 per cent. cottonseed oil; one group received 24 mg. diethylstilbestrol implanted subcutaneously each month for 1 to 10 months, another 2 per cent. cholesterol in the diet for 1 to 11 months. Birds were killed at intervals during these treatments and for up to 12 months after the last hormone implant or 8 months after withdrawal of cholesterol.

Both treatments produced high plasma lipid values, which fell when treatment stopped. Two of the control birds showed intimal thickening of the thoracic aorta as a result of lipid infiltration; some lipid infiltration was found in the thoracic aorta of about half the group, but cholesterol in none. All but one of the group showed intimal thickening of the abdominal aorta, but this was primarily fibrous and lipid substances appeared later. Traces of refractile substance, probably cholesterol, were seen in 3. The lesions in the experimental groups were similar, but more severe because there was more lipid infiltration. Thoracic lesions regressed when stilbestrol or cholesterol was withdrawn, but the abdominal lesions showed little or no regression. Cholesterol and calcified material continued to accumulate in the abdominal aorta after the blood lipid levels fell.

It is suggested that in man, too, diets designed to reduce plasma lipids and cholesterol will produce little regression once severe arteriosclerotic lesions have been established.—D. Duncan.

WELLS, W. W. and BAUMANN, C. A. Skin sterols
7. Removal of Δ^7 -cholesterol from blood
of rats. *Proc. Soc. Exp. Biol. Med.*, 1954, **87**,
519-521. [Dept. Biochem., Coll. Agric., Univ.
Wisconsin, Madison.]

An emulsion containing Δ^7 -cholesterol or its
acetate was injected into the heart of anaesthetised
adult rats, in amounts ranging from 5 to 14.7 mg.
per 200 g. rat. Blood samples and organs were
removed at intervals and analysed for Δ^7 -chole-
sterol.

Less than half the injected sterol or its acetate
remained in the blood after 2 hr.; at this time 34
per cent. of the amount was accounted for in the
lungs, spleen and liver. These organs still con-
tained 26 per cent. of the amount injected after
24 hr.; most was in esterified form. Injected
 Δ^7 -cholesterol acetate was metabolised without
any corresponding accumulation of free sterol.
Transient increases in the cholesterol content of
liver, spleen and lungs were observed after injection
of free Δ^7 -cholesterol.—G. A. Garton.

VAN PUTTEN, L. M., VAN BEKKUM, D. W. and
QUERIDO, A. Influence of hypothalamic
lesions producing hyperphagia, and of feeding

regimens on carcass composition in the rat.
Metabolism, 1955, **4**, 68-74. [Dept. Endo-
crinol., Hosp. Univ. Leyden.]

Bilateral hypothalamic lesions in rats were so
placed as to produce increased appetite for food.
Controls had a sham operation. The rats with
lesions were paired with controls and allowed the
quantity of food voluntarily consumed by the
controls. In a second, similar experiment all the
rats were trained to eat their daily ration in 2
periods of 1 hr. each, to eliminate differences in the
rate of eating.

There was no difference in bodyweight increase
between rats with and without lesions, but in the
first experiment the mean body fat contents were
 30.5 ± 9.1 and 15.3 ± 3.3 per cent., respectively.
Differences in N and glycogen content were
negligible, so the difference in fat content was
thought to be due to lower energy expenditure by
the rats with lesions. In the second experiment
all the rats except 6 pairs had to be eliminated
for one reason or another, but the difference in fat
content appeared to have been reduced or pre-
vented by restriction of the time spent in eating.

ORTIZ DE LANDAZURI, E. La respuesta a la
hipercalcemia provocada en el metabolismo
Ca/P en el hipoparatiroidismo. [The response
of the metabolism of calcium and phosphorus

Vol. 25, No. 3

to induced hypercalcaemia in hypopara-
thyroidism.] *Rev. clín. española*, 1954, **55**,
72-80. [Clín. Med. Univ., Secc. C.S.I.C.,
Granada.] English, German and French
summaries.

The "normal" subject had a diagnosis of hys-
teria and a tendency to high serum Ca levels, and
the experimental subject had idiopathic para-
thyroid insufficiency. Each received 15 mg. Ca
per kg. bodyweight by intravenous infusion lasting
4 hr., with 1 litre of saline.

In the normal subject serum Ca rose in 6 hr.
from 14.7 to 17.7 mg. per 100 ml. and serum inor-
ganic P rose in the same time from 2.75 to 3.6
mg. per 100 ml. Phosphate excretion in the urine
fell from 703 and 709 mg. on the 2 control days to
320 mg. on the day of injection, but rose again
the next day to 798. Ca in the urine was 40.7
and 79.4 mg. on the control days, 466.7, 223.2 and
189 mg. on the day of injection and the next 2
days, i.e., 61, 21 and 17 per cent. of the dose
injected was recovered in 3 days. In the hypo-
parathyroid subject serum Ca rose in 6 hr. from
5.1 to 8.6 mg. per 100 ml., but inorganic P remained
constant, 6.8 and 6.75 mg. Phosphate excretion
rose from 580 and 632.5 mg. on the control days to
1117 mg. on the day of injection. Ca in the urine

rose only from 114 and 55.2 mg. to 231, and fell on the subsequent days to 41.3 and 81.5 mg. Thus only 25 per cent. of the dose injected was recovered on the first day.

It is concluded that in the normal subject the rise of serum Ca provoked mobilisation of tissue P and inhibition of the parathyroid, which reduced the loss of P in the urine and thus resulted in higher serum P. In parathyroid insufficiency the first effect takes place but not the second, and increased loss of P prevents a rise of the serum level. It is suggested that the lower recovery of Ca indicates an increased deposition of Ca and P in the skeleton.

BRONNER, F., HARRIS, R. S., MALETSKOS, C. J. and BENDA, C. E. Studies in calcium metabolism. Effect of food phytates on calcium ⁴⁵ uptake in children on low-calcium breakfasts. *J. Nutrition*, 1954, **54**, 523-542. [Dept. Food Technol., Massachusetts Inst. Technol., Cambridge.]

Nineteen adolescent boys of poor intelligence but otherwise normal, who lived in a state school under uniform nutritional and environmental conditions, were given daily for one month a quart of milk and one multivitamin tablet. The subjects then received one of 3 different breakfasts, consisting of oatmeal, farina or farina with added sodium phytate; the 3 meals also included, respectively,

55, 60 and 60 ml. milk, 91, 83 and 83 mg. Ca, 116, 0 and 78 mg. phytin P and 0.85, 0.85 and 0.85 μ C. radio-active Ca. Ca uptake was estimated from the ⁴⁵Ca content of serum, urine and faeces during the 5 days after the test meal. Each subject received 2 of the breakfasts with 30 days between. Results are analysed statistically.

The uptake of ⁴⁵Ca by boys given the oatmeal breakfast was 74 per cent. of that shown by boys given the farina breakfast; the uptake of ⁴⁵Ca by boys on the farina meal with phytate was 45 per cent. of that of farina alone. The differences were significant at the 5 per cent. probability level. Significantly less ⁴⁵Ca was taken up in the presence of sodium phytate than in the presence of an equivalent quantity of phytates P supplied by oatmeal.—G. F. Garton.

BLAU, M., SPENCER, H., SWERNOV, J. and LASZLO, D. Utilization and intestinal excretion of calcium in man. *Science*, 1954, **120**, 1029-1031. [Div. Neoplastic Dis., Montefiore Hosp., New York.]

Two subjects on a diet low in Ca were given single doses by mouth of 50 μ C. of ⁴⁵Ca with 30 mg. Ca as carrier. Serum, urine and faeces were analysed for Ca and ⁴⁵Ca, balances being measured for four 6-day periods. Radio-activity appeared in blood 15 min. after ingestion of ⁴⁵Ca. Specific activities of serum and urine soon became equal and fell exponentially with a half-time of 8 or 9 days. On the assumption that the ratio of the specific activity of the faeces to that of the plasma or urine represents the fraction of endogenous Ca in faeces, utilisation by the subjects was calculated to be 44 and 67 per cent. of ingested Ca. Good agreement with these findings was obtained when the calculation was made from the total excretion of ⁴⁵Ca in faeces less an amount of endogenous origin arrived at by extrapolation of the graph for specific activity of the faeces.

An extension of the technique to the study of the calcium compartments of the body is being investigated.—D. Harvey.

DAUM, K., TUTTLE, W. W., WEBER, A., SCHUMACHER, M. T. and SALZANO, J. Calcium and phosphorus utilization in older men. *J. Amer. Dietetic Assoc.*, 1955, **31**, 149-151. [Dept. Nutrit., State Univ. Iowa, Iowa City.]

Results are presented of Ca and P balance studies of 7 men aged from 53 to 83 years who were the subjects of an investigation of the physiological effects of different breakfasts (*Abst.* 771, Vol. 22). On the basis of group means the daily intake and balances of Ca and P were not significantly influenced by the type of breakfast. Ca retentions

were slightly less than in a group of younger men, subjects of a similar experiment (Abst. 3705, Vol. 21), but the differences were not significant. Urine Ca values for the older men tended to be low. Urine P values were about 50 per cent. of intake.—F. C. Aitken.

MOORE, J. H. and TYLER, C. Studies on the intestinal absorption and excretion of calcium and phosphorus in the pig. 1. A critical study of the Bergeim technique for investigating the intestinal absorption and excretion of calcium and phosphorus. 2. The intestinal absorption and excretion of radioactive calcium and phosphorus. *Brit. J. Nutrition*, 1955, 9, 63-80; 81-93. [Dept. Agric. Chem., Univ. Reading.]

1. Six pigs 9 to 10 weeks old were fed for 7 days on a diet containing 1.67 per cent. Ca, mostly as carbonate, and 0.78 per cent. P. On the following day pairs of pigs were killed 2, 4 and 6 hr. after the morning feed. The digestive tract was divided into 12 sections and the contents of each were analysed for pH, dry matter, soluble Ca and P, insoluble ash, total Ca and P and phytate P.

The contents of the stomach, particularly in the pyloric region, became increasingly acid with increasing time after feeding, but the pH values of the contents of all sections of the small intestine were relatively constant.

Absorption of Ca and P was most active in the upper parts of the small intestine. There was no evidence of excretion of either Ca or P into the large intestine. Hydrolysis of phytate apparently took place in the stomach until the pH was sufficiently low to inhibit phytase, which happened between 2 and 4 hr. after feeding.

2. Two pigs 9 to 10 weeks old were fed for 10 days on a diet containing 2 per cent. calcium phosphate. On the 11th day the morning feed contained radio-active Ca and P as calcium phosphate and the animals were killed 4 hr. after feeding. A similar pair of pigs were fed on the diet with the labelled Ca and P for 10 days, then on the inactive diet for 4 days, and were killed next day 4 hr. after the morning feed. The contents of the digestive tract were analysed as in the previous experiment. In addition, radio-active Ca and P were estimated as well as total and radio-active

Ca and P in the wall of each section of the digestive tract.

The most active absorption of Ca and P was again in the upper parts of the small intestine, in which the solubilities of Ca and P were greatest. P and, to a small degree, Ca was secreted into the upper part of the small intestine, but much was re-absorbed in the lower parts. There was little evidence that Ca and P were excreted into the large intestine.

The contents of the large intestine were slightly more acid in pigs fed on calcium phosphate than in those fed on calcium carbonate. The difference was apparently responsible for the greater degree of phytate hydrolysis in the large intestine of phosphate-fed pigs.—R. Hill.

3873

ARRINGTON, L. R. and DAVIS, G. K. Metabolism of phosphorus³² and molybdenum⁹⁹ in rats receiving high calcium diets. *J. Nutrition*, 1955, 55, 185-192. [Florida Agric. Exp. Stat., Gainesville.]

Of 2 groups of 24 mature rats one received a diet containing, in g., powdered whole milk 3415, sucrose 3380, NaCl 34, FeSO₄.7H₂O 0.136, MnSO₄.2H₂O 0.06, CuSO₄.5H₂O 0.1, thiamine hydrochloride 0.023 and pyridoxine hydrochloride 0.033; the Ca : P ratio was 1.3 : 1. The second group received a diet in which the Ca : P ratio was 3 : 1, prepared by adding CaCO₃ to the basal diet. The diets were given to appetite and caliciferol was given weekly. After 5 weeks the rats were given, by mouth, either 5 μ C. ³²P or 15 μ C. ⁹⁹Mo; collections were made of urine and faeces and at the end of the metabolism period the animals were killed.

When Ca intake was high there was less excretion in the urine and more tissue deposition of ³²P. The metabolism of ⁹⁹Mo was not affected by the high Ca intake; the ⁹⁹Mo was excreted extremely rapidly, 50 per cent. being recovered in the urine within 12 hr.—G. F. Garton.

3874

RANDOIN, L., LE GALLIC, P. and FOURNIER, P. Conceptions nouvelles du besoin en calcium dans ses rapports avec l'équilibre fonctionnel. [New views on calcium requirement in relation to functional equilibrium.] *C.R. Acad. Sci.*, 1955, 240, 230-232.

Rats received a low-protein diet with 4 per cent. casein, either to appetite, about 8 g. daily, or restricted to 5 g. After 10 days they received stock diet for 2 days and the experiment was then repeated with the groups reversed. The amount of Ca retained was closely related to the food intake. When the intake of Ca was reduced because of low food intake the coefficient of utilisation did not

rise. It is concluded that there is a functional equilibrium between utilisation of Ca and energy intake, and this relation is to be studied.

PATRICK, H. and SCHWEITZER, G. K. Factors associated with the movement of calcium from the food to the bones of chicks. *Poultry Sci.*, 1954, **33**, 1199-1201. [Univ. Tennessee, Knoxville.]

Chicks were fed for 5 days after hatching on ground wheat, and thereafter on a soya bean basal diet containing different quantities of added Ca. Radio-active Ca as chloride was injected on the thirteenth day after hatching and 36 hr. later the birds were killed. The amount of radio-active Ca in the tibia was inversely related to the amount of Ca in the diet.

The addition of casein or milk albumin to a groundnut basal diet containing large amounts of Ca and P increased the proportion of radio active Ca in the tibia. The ash of casein did not give this effect.

The substance affecting the retention of Ca in the tibia apparently operated directly on bone and not by any effect on absorption.—R. Hill.

NAKAJIMA, T., OMORI, S. and OTSUKA, J. [On the influence of the feed upon bones. 9. Skeletal calcium turnover in rats reared with cereals.] *Bull. Nat. Inst. Agric. Sci., Japan* [G], 1954, No. 9, 81-87. In Japanese: English summary.

Three groups of young rats were given a complete diet, polished rice only or rye only for 40 days, at the end of which each animal was given by mouth a dose of $^{45}\text{CaCl}_2$. They were killed after 1, 2, 5 or 10 days and by examination of the radio-activity of humerus, distal epiphysis and diaphysis of femurs it was found that the turnover of Ca in those given rye, which had developed osteoporosis, differed from that in the animals given unpolished rice, in which a rickets-like condition occurred.

In osteoporosis there was more ^{45}Ca in the shafts of the long bones than in normal rats or in those with the rickets-like disease; for the distal epiphysis of the femur the opposite was true. (From summary.)—D. Harvey.

DARROW, D. C., COOKE, R. E. and SEGAR, W. E. Water and electrolyte metabolism in infants fed cow's milk mixture during heat stress. *Pediatrics*, 1954, **14**, 602-617. [Med. Centre, Univ. Kansas, Kansas City 3.]

Complete balance studies of water, fat, N, Cl, Na, K and Ca were made on healthy male infants aged less than 1 year while exposed to a hot and a cool environment. Eight milk mixtures were tested as feeds during these studies; 6 consisted of evaporated milk with or without added carbohydrate and diluted with water to different extents. One of the 6 had skimmed milk added as well as carbohydrate. Two mixtures, of high and low electrolyte content, were made from dialysed milk solids, water, added carbohydrate and the required amounts of Na, K and Cl.

The results confirmed previous observations that water, Na and Cl were retained during exposure to a hot environment. At water intakes of 150 ml. per 100 Cal. the usual cow's milk mixtures with or without added carbohydrate did not lead to concentration of urine approaching the physiological limits in the hot environment. Protein or electrolyte concentrations greater than in the usual evaporated milk mixtures produced more concentrated urines. Limitation of water to 100

N.A. and B., July 1955

ml. per 100 Cal. of evaporated milk mixture induced maximum urinary concentration at the high temperature, with signs of impending heat prostration.—F. C. Aitken.

ZETTERSTRÖM, R. and ÅBERG, B. Infants of diabetic mothers. 2. Studies on the electrolyte metabolism and the effects of starvation during the first days of life. *Acta paediat.*, 1955, **44**, 1-16. [Paediat. Clin., Karolinska Sjukhuset, Stockholm.] French, German and Spanish summaries.

In the 10 infants studied food and water were withheld for the first few days of life because of generalised oedema. During this time there was no tendency to pathologically low blood sugar, blood N.P.N. was not abnormally high and serum electrolytes were within normal limits.

Cumulative electrolyte balance was studied in 5 of the infants. During starvation there was continued loss of Na, K and Cl. When milk was given there was considerable retention of K, but at first the loss of Na continued and was greater than the loss of Cl in relation to the composition of extracellular fluid.—F. C. Aitken.

ANDERSSON, B. Observations on the water and electrolyte metabolism in the goat. *Acta physiol. scand.*, 1955, **33**, 50-65. [Dept. Physiol., Kgl. Veterinärhögsk., Stockholm.]

The experiments were made on fullgrown goats weighing from 35 to 40 kg., some with free access to salt and others having had none for more than 3 months. Large volumes of water, up to 20 per cent. of bodyweight, could be introduced through a rumen fistula without producing intoxication; after such treatment the rate of excretion rose from the normal of 50 ml. to as much as 1200 ml. hourly. Diuresis persisted for up to 6 hr. and the return to normal required as long as 7 hr. more. Pituitrin given after diuresis was established caused an immediate but temporary reduction in it.

Some goats developed polyuria spontaneously on undergoing preparation for the experiments. This was most frequent in animals without access to salt and in its response to pituitrin this form resembled water diuresis. Injections of 0.5 mg. adrenaline or 50 mg. ephedrine by vein generally produced polyuria with increase of excretion in urine of Na and Cl and of inulin clearance in goats with and without access to salt. The concentrations of Na and Cl in urine differed; in those with access to salt and in which they were already high, concentrations fell towards plasma levels after injection, but in those without access to salt and in which they were low, concentrations rose.

MEYER, J. H., WEIR, W. C. and SMITH, J. D. A study of sheep during starvation and water deprivation. *J. Animal Sci.*, 1955, **14**, 160-172. [Dept. Animal Husband., Univ. California, Davis.]

Two pairs of sheep in metabolism crates were starved and deprived of water for 36 hr., followed by 9 hr. on water only before restoration to full feed. One pair had a ration calculated to satisfy TDN requirements and the other had the same plus 11 per cent. NaCl. Both got water to appetite.

27

Before starvation the pair receiving extra salt drank 3 times as much as the other pair, and after starvation did not return to this level until feed was given again. During the early period when feed was given again, all sheep refused one or more feeds. Before starvation the pair getting NaCl had a much greater flow of urine, but in both pairs urine was reduced during starvation, especially in the NaCl pair. In both pairs the Na, Cl and K excreted in the urine followed the same pattern as the volume of urine. With the sheep on NaCl there was a marked decrease in urine N, but in the other pair the decrease was very slight. Plasma albumin and haematocrit rose during starvation in the pair getting NaCl. The pair on the basal ration lost 5 per cent., and the other pair 7.5 per cent. of bodyweight during starvation. N and extracellular fluid were lost by both pairs during starvation.—T. D. Bell.

KEMPNER, W., PESCHEL, E. and BLACK-SCHAFER, B. Effect of diet on experimental hypertension and on the development of polyarteritis nodosa in rats. *Circulation Res.*, 1955, 3, 73-78. [Dept. Med., Sch. Med., Duke Univ., Durham, N.C.]

High blood pressure was produced in female rats by removing one kidney and enclosing the other in a latex capsule; both operations were completed by the time the rats were 45 to 50 days old. Until high blood pressure was established the rats were fed on dog chow and tap water, and then 5 groups with comparable ranges of systolic pressure received different diets, with 4 sub-groups on each diet. The diets, in order of decreasing Na intake, were dog chow, bread, meat, peas and rice. The sub-groups received no extra salt, 50 mg. KCl, 100 mg. NaCl, or 50 mg. KCl plus 100 mg. NaCl daily, given in 5 ml. solution before tap water was supplied *ad libitum*. Vitamin supplements were given.

Control, unoperated rats had systolic pressures between 90 and 120 mm. Hg, which were independent of diet and salt intake. In operated rats the systolic pressures after from 4 to 7 days were between 160 and 200 mm. Hg. There was always some degree of damage to the remaining kidney, and renal insufficiency with rising blood urea concentration was common.

There was no difference between the sub-groups receiving KCl and those receiving no salt, or between those given NaCl plus KCl and those given NaCl only, so the groups are considered as 2 instead of 4. There was no significant difference in blood pressure between any diet sub-groups except that in the sub-group on rice diet without NaCl, a lower average systolic pressure of 170 mm. Hg in 24 rats included the pressures of the only

10 rats of the whole series which returned to normal. In this group even the rats with persistently high systolic pressure survived longer than those of other groups and on the average survival was about 6 times as long as in rats fed on chow, bread or meat without NaCl supplement. Rats on peas without NaCl lived half as long as those on rice. Additional NaCl reduced the survival time significantly only in rats fed on peas or rice.

Of 132 rats examined histologically, 31 showed typical *polyarteritis nodosa*. The incidence was highest in the rats on dog chow and bread, with or without NaCl; in these groups taken together 15 out of 31 rats had lesions. On unsupplemented meat, peas or rice only 2 of 52 animals had lesions, but on these diets with added NaCl the incidence was 14 out of 49. The one rat fed on peas alone and the one on rice alone which did develop lesions nevertheless survived 364 and 344 days after operation, and the last-mentioned rat had most of its remaining kidney tissue replaced by a sarcoma.

It is concluded that the rice diet greatly increased survival and reduced the risk of *polyarteritis nodosa* in experimental high blood pressure.—D. Duncan.

BAUER, G. C. H. Metabolism of bone sodium in rats investigated with Na^{22} . *Acta physiol. scand.*, 1954, 31, 334-350. [Orthopaedic Clin., Malmö, Sweden.]

Rats of 2 series each received a single subcutaneous injection of about 90 μCi of ^{22}Na . Rats of the adult series were killed after 1 to 120 hr., rats injected at 6 weeks of age were killed after 1 to 64 days. Bones and teeth were analysed.

Blood serum Na showed a steady fall in specific activity. In the mature rats, specific activity of bone samples rose rapidly in the first 8 hr. and then remained constant until the end of the 120-hr. experiment. Specific activity was highest in growing ends of bone and lowest in the shafts of tibias and femurs. Activity of incisor teeth rose rapidly at first, but continued to rise more slowly until the end of the experiment. If the amount of Na ascribable to the amount of water in bone and tooth samples was supposed to have the same specific activity as the serum Na, the specific activity ratio of the excess bone Na: serum Na was almost identical in all the samples. The excess bone Na estimated in this way suggested Na:Ca ratios by weight of between 1:35 and 1:60.

In the young rats the serum specific activity, high at the end of the first day, fell more rapidly and to lower values than the initially lower specific activity of bone. The bone values fell more rapidly in the growing ends than in the shafts of long bones. At 25 days after the injection there was 10 times as much specific activity in bone as

in serum; at 64 days the specific activity in the shafts had not fallen, but that of the serum was zero. The labelled Na incorporated into the growing bone or tooth was thus partly fixed in a stable form, estimated to represent 60 to 70 per cent. of the excess bone Na and half the excess Na in the teeth.

Deductions are made about the rate of incorporation of Na into the stable fractions.

CHEROUX, R. Les déficiences potassiques en clinique humaine. [Potassium deficiencies in the human clinic.] *Bull. Soc. sci. Hyg. aliment.*, 1954, **42**, 139-151.

A review.

3892

MCCALLEN, P. M. Myocardial changes occurring in potassium deficiency. *Brit. Heart J.*, 1955, **17**, 5-14. [W. Middlesex Hosp.]

Clinical, biochemical and post-mortem findings in 2 patients with well-established prolonged potassium deficiency are presented. In each extensive myocardial lesions were present, yet the coronary arteries were patent and free from disease. There was close resemblance between the myocardial changes and those constantly found in experimental K deficiency. The cardiac lesions are considered to be the direct result of K deficiency, and the findings indicate that a low K state should be corrected as quickly and completely as possible, in order to avoid permanent cardiac injury.

LENKEIT, W. and STAHN-TAUPITZ, E. Zu dem Einfluss steigender Kaliungaben, nach Versuchen an Hühnern. [Effect of increasing amounts of potassium in feed, in experiments with poultry.] *Arch. Tierernährung*, 1954, No. 5, Beihefte, 197-209. [Inst. Tierphysiol., Univ. Göttingen.]

The subjects were 4 hens initially 6 months old, weighing 1481 to 1781 g. and at the beginning of the laying period. The basal ration consisted, in g. per hen daily, of wheatmeal 66, fishmeal 4, yeast 5, casein 3, cellulose 2 and calcium phosphate 4; it supplied 0.27 to 0.31 g. K daily, and 0.145 g. Na. Distilled water was supplied and was used also for mixing the diet. Extra K was given as chemically pure KHCO_3 in aqueous solution twice daily by stomach tube. In successive periods of about a month the total daily intake in g. was 0.31, 1.29, 1.84, 1.84, 2.65, 3.43 and 4.99, or from 190 to 4340 mg. per kg. bodyweight.

With intakes up to 2.65 g. (60 m. equiv.) of K daily, appetite and egg production were not impaired, but with higher amounts both were

adversely affected. When the dose was increased above 5 g. the hens died in 36 hr. One hen given 2.65 g. without a gradual increase in intake died within 36 hr. The volume of excreta increased progressively, but although there was an initial increase in dry matter excretion normal levels were regained after about the first month. K excretion rose with K intake and the K content of the eggs was not affected. Blood K was affected only by the highest dose of K. Up to 1.84 g. K did not affect Na excretion, but in one hen it was increased by higher doses. Na depletion was not demonstrable, nor any effect on N, Ca and P metabolism.

MCCLENDON, J. F. and GERSHON-COHEN, J. Reduction of dental caries and goiter by crops fertilized with fluorine and iodine. *J. Agric. Food Chem.*, 1955, **3**, 72-73. [Dept. Res. Biochem., Albert Einstein Med. Centre, N. Div., Philadelphia, Pa.]

Two groups of rats were fed from weaning at 22 days till 3 months of age on diets composed of maize grain and roots, camellia leaves and yeast, containing 3.1 and 66.3 p.p.m. of fluorine, respectively. The maize and camellia leaves were grown on soil heavily fertilised with Tennessee brown rock phosphate containing 3.6 per cent. F, 12 tons to the acre. The control diet was obtained by hydroponic culture. The rats fed on the crops with the high F content gained more weight than the controls. The bones were normally calcified, as seen by X-ray examination. The incidence of dental caries was lower. The incisors showed fluorosis.

A similar experiment was made with sunflowers grown on plots iodised with different I compounds. Most of the rats fed on the low-iodine diet developed goitres, which did not occur in rats fed on the plants grown on iodine-fertilised plots.

MUHLER, J. C. and WEDDLE, D. A. Utilizability of fluorine for storage in the rat when administered in milk. *J. Nutrition*, 1955, **55**, 347-352. [Dept. Chem., Indiana Univ., Bloomington.]

In the first experiment weanling rats were given 5 p.p.m. F in a dry diet, in milk or in water; in the second, rats between 55 and 60 days of age had 10 p.p.m. [but 5 p.p.m. stated on p. 348] in milk or in water, and in the third weanling rats had 2 p.p.m. in milk or in water. The total amounts of F ingested in 40 days were 1.64, 6.87

and 1.33 mg. per rat in the 3 groups. Estimations were made of F in one femur and in the remainder of the carcasses.

In the first test F was least readily available from the dry diet and there was evidence, which was not considered significant, that it was retained in greater amount from water than from milk. The second test did not confirm this difference between milk and water groups. In the third test there was a significant difference in retention of F in favour of the water group.

It is concluded that, for the concentration of F required for human consumption, milk would be less suitable as a vehicle than water. The suggested explanation is that at the lower concentration, 2 p.p.m., the Ca and Mg in milk may interfere with the availability of F and that at the higher, 10 p.p.m., there is no such interference.

D. Harvey.

3896

MUHLER, J. C. Retention of fluorine in the skeleton of the rat receiving different levels of fluorine in the diet. *J. Nutrition*, 1954, **54**, 481-490. [Dept. Chem., Univ. Indiana, Bloomington.]

Four diets containing 3.1, 2.2, 1.8 and < 0.1 p.p.m. F were given to groups of rats; the drinking water for the first 3 contained 0.09 and that for the fourth 0.005 p.p.m. F. In all 222 rats were used and the extent of storage of F was measured by estimation of the F content of their femurs after varying periods of feeding.

In both sexes the concentration decreased when a certain age was reached. With 3 p.p.m. F in the diet the age was between 50 and 90 days, with 2.2 p.p.m. about 80 days and with < 0.1 p.p.m. about 50 days. The total F content of the femurs did not decrease. There was a sex difference; the concentration in females was greater than in males after it had begun to fall in both sexes. In a paired-feeding experiment with a diet with 1.8 p.p.m. F, in which the female was fed to appetite and the male was given the same amount of food, the fall in concentration was confirmed at about 70 days, and the sex difference again appeared. It is thought to have been due possibly to differences between the sexes in the rate of skeletal growth.

WALLACE-DURBIN, P. The metabolism of fluorine in the rat using F^{18} as a tracer. *J. Dent. Res.*, 1954, **33**, 789-800. [Div. Med. Phys., Univ. California, Berkeley.]

Young adult and mature female rats were used in studies in which F^{18} was administered by mouth or by intravenous injection in the carrier-free state or with added fluoride carrier.

Disappearance of injected F from the blood was rapid and equilibrium was quickly established

between F^{18} in the blood and in most of the tissues. Fifteen minutes after injection levels in tissues which are highly vascular, liver, spleen and small intestine, were nearly the same as in blood. In all tissues except kidney and salivary gland they remained nearly parallel to the levels in blood. There was some evidence of excretion in faeces. Deposition was mainly in teeth and bones and to a less extent in cartilage; there was no accumulation in the thyroid.

Distribution in soft tissues was not affected by the age of the animal, but the uptake by teeth and bones was less in mature than in young adult rats. It was the same whether the F was given by mouth or by vein.—D. Harvey.

3898

WEDDLE, D. A. and MUHLER, J. C. The effects of inorganic salts on fluorine storage in the rat. *J. Nutrition*, 1954, **54**, 437-444. [Dept. Chem., Indiana Univ., Bloomington.]

About 100 weanling rats were divided into 6 groups, of which one received 2 ml. of aqueous NaF solution containing 1000 μ g. F per ml. daily; for a second group sufficient $CaCl_2$ was added to the fluoride solution to give final concentrations of 1.0, 0.1 and 0.01 per cent. Ca and to make the final F concentration identical with that received by the animals of the first group. A third group received Ca pyrophosphate at a Ca concentration of 0.1 and 0.01 per cent., a fourth group $MgCl_2$ at 1.0, 0.1 and 0.01 per cent. Mg, a fifth group Al chloride at 1.0, 0.1 and 0.01 per cent. Al and the sixth group Al oxide at 0.1 and 0.01 per cent. Al. All the animals received the same stock diet containing 0.5 μ g. F per g. and drinking water containing 0.05 μ g. F per ml. The experimental solutions were all given by stomach tube once daily for 14 days, after which the animals were killed and F was estimated in the right femur and in the remainder of the carcass.

In a second series of experiments 18 rats were divided into 3 groups: the first received a stock diet to which was added sufficient NaF to produce a fluoride concentration of 5 μ g. per g., the second received an identical concentration of F in the drinking water, and the third group had no F supplement and acted as control. After 40 days both experimental groups were estimated to have had identical amounts of F and the animals were killed and analysed as before.

Ca, as $CaCl_2$, decreased F storage in the skeleton even when administered at a concentration of 0.01 per cent.; Ca pyrophosphate and Al oxide did not alter F storage. Mg, as $MgCl_2$, and Al, as chloride, decreased F storage; the effect of Al was more pronounced than that of Mg and both had a more pronounced effect on Ca. In the second series of experiments, when fluoride was added to

the dry diet there was less F in the skeleton than when identical amounts were taken in the drinking water. A maximum of 50 per cent. of the total F ingested was stored in the entire carcass when the F was given in aqueous solution.

MUHLER, J. C. and DAY, H. G. **Effect of pH and state of oxidation of different fluorides in the drinking water on dental caries and fluoride storage in the rat.** *J. Dent. Res.*, 1955, **34**, 68-72. [Dept. Chem., Univ. Indiana, Bloomington.]

In continuation of earlier work (see Abst. 3402, Vol. 24), groups of about 40 weanling rats on a cariogenic diet were given 20 μ g. F as stannous fluoride, stannous chlorofluoride or sodium fluoride in oxygen-free drinking water at pH 3.5 or 5.5, or no supplement.

At pH 5.5 the tin compounds were not more effective than NaF in reducing dental caries. Their activity at pH 3.5 was less in another experiment in which the water contained oxygen.

As was found before, the amount of F stored in the femur was less with the tin compounds than with NaF; it was unaffected by pH.

OKUSHI, I. **Changes of the heart muscle due to chronic fluorosis. 2. Experimental studies on the effects of sodium fluoride upon the heart muscle of a rabbit.** *Shikoku Acta Med.*, 1954, **5**, No. 4, 52-59. [Dept. Int. Med., Sch. Med., Tokushima Univ.] Japanese summary.

Groups of 11, 10, 13 and 3 rabbits were given 10, 30, 50 and 100 mg. NaF per kg. bodyweight daily by mouth; a fifth group of 16 animals received no additional F. The periods of administration of F were from 81 to 135, 14 to 80, 2 to 114 and 3 to 5 days. At the end the rabbits were killed and histological examinations were made of their hearts.

Electrocardiographic changes were depression of ST and inversion of T waves and prolongation of QT interval; histological changes were infiltration of cells, hyperaemia, haemorrhages and thickening of the vessel walls. They are discussed in relation to earlier findings in man (Abst. 2640, Vol. 25).

KONO, K., OKUSHI, I., HIRAO, M., KAWAHARA, H., KAKIHARA, H. and AKAIKE, K. **[The heart changes of growing albino rats fed on varied contents of fluorine.]** *Shikoku Acta Med.*, 1954, **5**, No. 4, 104-107. [Dept. Int. Med., Sch. Med., Tokushima Univ.] In Japanese: English summary.

Vol. 25, No. 3

Growing rats aged between 30 and 50 days were given a diet containing 375, 100, 50, 10 or 5 p.p.m. F as NaF, amounts equivalent, respectively, to between 24.2 and 31.0, 10.7 and 12.2, 5.8 and 6.9, 1.1 and 2.9, and 0.5 and 0.7 mg. per kg. bodyweight. Littermates were kept as controls with no added NaF.

The changes in myocardial fibres of the animals given F were cloudy swelling, vacuolar degeneration, infiltration of round cells and small haemorrhages; their extent corresponded to the level and duration of feeding, but individual differences occurred. These changes in rats were thought to be less severe than those in rabbits similarly treated (preceding Abst.).—D. Harvey.

3902

FLEMING, H. S. and GREENFIELD, V. S. **Changes in the teeth and jaws of neonatal Webster mice after administration of NaF and CaF₂ to the female parent during gestation.** *J. Dent. Res.*, 1954, **33**, 780-788. [Dept. Pathol., Sch. Med., Yale Univ., New Haven, Conn.]

Fluoride was given to mice during pregnancy, in drinking water as NaF in 80 and CaF₂ in 50 and as injections of NaF in 60 and CaF₂ in 55. It was estimated that the intakes by mouth were from 60 to 80 μ g. daily and the amounts injected were 100 μ g. daily, each in terms of NaF or CaF₂. Administration throughout pregnancy often caused resorption of the foetuses; it was, therefore, generally limited to the latter half of gestation. Illustrations typical of the histological changes are reproduced.

Calcification of bone in the jaws of the newborn mice was retarded and there was alteration of the cell structure of the ameloblasts with retardation of maturation of the enamel matrix. The pulp vessels in the teeth appeared hyperaemic. The Ca salt seemed to be more toxic to the foetuses than the Na salt.—D. Harvey.

3903

WYNN, W. and HALDI, J. **Dental caries in the albino rat on fluoridated and distilled water.** *J. Nutrition*, 1955, **55**, 235-240. [Dept. Physiol., Div. Basic Sci. Health Serv., Emory Univ., Emory University, Ga.]

Two diets, one of which readily produced caries (Abst. 2665, Vol. 22) and the other rather less readily, were each given to 30 pairs of littermate rats for 80 days. To accelerate the appearance of caries the salivary glands were removed from all animals (see Abst. 4882, Vol. 23). Of each pair of rats one drank distilled water free from F and the other the same amount of tap water containing between 0.7 and 1.0 p.p.m. F. The amount of F thus given had no effect on the incidence of caries with either diet.—D. Harvey.

3904

RICHARDSON, A. W., MUHLER, J. C. and BISHOP, J. G. The vasodepressor response of fluorine administered orally to dogs. *J. Pharmacol. Exp. Therap.*, 1955, **113**, 200-205. [Dept. Physiol., Sch. Med., Univ. Indiana, Bloomington.]

NaF or SnF₂ was given by stomach tube in amounts of 1 or 5 mg. F to 28 dogs and measurements were made of blood pressure and F content and of pulse pressure, heart rate, and rate of blood flow. After 45 min. the blood pressure had fallen by 3 and 16 per cent. and by 9 and 11 per cent., respectively, for the 1 and 5 mg. doses as Na and Sn salts. Blood F 45 min. after administration of 5 mg. F showed that absorption from NaF was much more rapid than from SnF₂. Changes in pulse pressure, heart rate and rate of blood flow were those expected of a hypotensive agent. For earlier work on intravenous injection of F see Title 2347, Vol. 25.—D. Harvey.

3906

RAY, C. T., THREEFOOT, S. A. and BURCH, G. E. Studies on the excretion of chloride by man with and without congestive heart failure, using long-life radiochloride, Cl³⁶. *J. Lab. Clin. Med.*, 1954, **44**, 663-701. [Dept. Med., Sch. Med., Tulane Univ., New Orleans, La.]

Four subjects with congestive heart failure and 2 controls, with thyrotoxicosis and tuberculous lymphadenitis, respectively, each received intravenously 50 μ Ci. of ³⁶Cl as NaCl. Blood, urine, ascitic and pleural fluids and faeces were collected at intervals for from 30 to 70 days, with frequent blood and urine samples in the first 2 hr.

³⁶Cl appeared in the urine within 7 min. after injection in all subjects and there was no detectable difference between the 2 groups. In the first 90 min. 3 subjects with oedema excreted the smallest amounts of ³⁶Cl, and their clearance rates of ³⁶Cl were lower than those of controls. The fourth subject, with mild heart failure and recovering, had the highest clearance rate of all.

At the end of 30 days 76.3 and 86.8 per cent. of the dose had been recovered from the control subjects; 75.2 and 82.8 per cent. in urine, 1.1 and 4.0 per cent. in faeces. For the 3 patients for

whom the exact dose injected was known, 60.8, 36.8 and 63.7 per cent. had been recovered, 54.7, 19 and 60.3 per cent. in the urine, 6.1, 2.0 and 1.6 per cent. in the faeces; from the second, 15.8 per cent. was in thoracic and abdominal fluid, and for the third, 1.7 per cent. in vomitus and sputum. Apparently little if any ³⁶Cl was permanently bound in the tissues. After 70 days from 95 to 99 per cent. had been recovered from 3 subjects.

The daily chloride balances were studied. The control subjects showed very similar curves of excretion of ³⁵Cl and ³⁶Cl when these were expressed as percentages of the amounts remaining in the body, but the curves of the 4 patients were irregular. The clearances of ³⁵Cl and ³⁶Cl were similar, except for discrepancies which are explained by lags in chloride exchange and sequestration.

Several aspects of chloride metabolism are discussed in the light of these findings.—D. Duncan.

See also Title 4904, Vol. 24.

In 32 healthy young people no significant difference was found in the amount of ⁵⁹Fe absorbed from bread enriched with ferrous sulphate, reduced iron, ferric orthophosphate or sodium ferric pyrophosphate. Of the 2 to 4 mg. ⁵⁹Fe in the test meal 1 to 12 per cent. was absorbed by 28 of the subjects. The other 4 subjects, who absorbed from 26 to 38 per cent. of the ⁵⁹Fe, were thought to have low Fe stores. In 3 subjects with Fe-deficiency anaemia absorption was of the order of 45 to 64 per cent. A supplement of ascorbic acid given with the enriched bread increased absorption of ⁵⁹Fe in normal subjects. The amount of ⁵⁹Fe

N.A. and R., July 1955

absorbed was about the same whether the ^{59}Fe salt was baked into the bread or given with un-enriched bread. Ferrous sulphate was better absorbed when given alone than when given in or with bread.

Methods of synthesising the ^{59}Fe salts are given in an appendix.—F. C. Aitken.

BERTOLANI, F., BENDANDI, A. and SQUADRINI, F. **Ricerche sulla mobilitazione di anormali depositi di ferro nel fegato. [Mobilisation of abnormal deposits of iron in the liver.]** *Arch. Sci. biol., Bologna*, 1955, 39, 1-7. [Ist. Clin. Med. Gen., Univ. Modena.]

A group of 20 rats weighing about 130 g. were fed for 37 days on a diet of whole flour 800 g., lard 200 g. and cod liver oil 15 ml., with a vitamin B complex preparation, and each rat received on the first, eighth and 20th day by intravenous injection 10 mg. Fe as saccharated iron oxide solution. A second group of 20 similar rats received the same diet for 27 days but with 3 per cent. ferric citrate added. Five animals from each group were then bled repeatedly for 4 months, and then they and 5 others from each group, not bled, were killed for estimation of liver Fe. Another 5 of each group had about 65 per cent. of the liver removed and were kept on the same diets for 2 days and then killed for a study of liver regeneration. Eight other rats fed on the diet containing ferrous citrate for from 4 to 8 days before partial

removal of the liver were killed from 48 to 96 hr. after operation.

Both bleeding and partial hepatectomy were followed by reduction in the amount of Fe stored in the liver, especially when the storage resulted from the Fe-rich diet. The reduction in concentration of liver Fe was greatest 72 hr. after partial hepatectomy.

Histologically the distribution of iron deposits after Fe injection was mainly reticulo-endothelial, while that after dietary Fe was parenchymal and especially periportal. Both types were much less after bleeding or partial hepatectomy.

It is concluded that Fe deposited in experimental siderosis can readily be mobilised.—D. Duncan.

[Phosphates and experimental siderosis.]** *Bol. Soc. ital. Biol. sper.*, 1954, 30, 169-170; 170-173; 173-175; 175-178. [Ist. Clin. Med., Univ. Modena.]

Seven groups of rats weighing from 130 to 180 g. were given extra iron in the diet or by intravenous injection, and part of the liver was removed from 2 groups. SH groups were estimated in the liver by the method of Fujita and Numata as previously used (*Bol. Soc. ital. Patol.*, 1953, 3, 65), but results were not consistent.

Rats weighing about 120 g. were given a diet containing ferric citrate. Some were given thyroxine, some had the adrenals removed and were given NaCl or deoxycorticosterone acetate, and some were given adrenocorticotrophic hormone. After about 40 days, Fe was estimated in the liver, spleen and kidneys and a histochemical examination was made. Administration of thyroxine caused a considerable rise in the Fe content of the liver, and adrenocorticotrophic hormone a moderate one, but deoxycorticosterone acetate had little effect. Removal of the adrenals was followed by a decrease.

Fifty-two rats weighing about 120 g. were maintained for 43 days on the diet mentioned above, containing ferric citrate, without addition or with

3 per cent. methionine or glycine or glutamic acid, or 1 per cent. of each or with 6 per cent. of amino-acids obtained from enzymic hydrolysis of casein and fibrin, or of the same hydrolysate subsequently treated with HCl to destroy tryptophan and tyrosine. The Fe content of the liver was higher with all diets containing ferric citrate than without it. Methionine and glutamic acid increased the pathological accumulation of Fe in the liver; glycine by itself had no effect, but with methionine and glutamic acid had some effect in counteracting their action. The enzymic hydrolysate counteracted the deposition of Fe, but its protective action was impaired by acid treatment.

In 2 other experiments administration of sodium phosphate, either by mouth or intramuscularly, tended to counteract the pathological deposition of Fe.—E. M. Hume.

EARL, C. J., MOULTON, M. J. and SILVERSTONE, B. **Metabolism of copper in Wilson's disease and in normal subjects: studies with Cu-64.** *Amer. J. Med.*, 1954, **17**, 205-213. [Dept. Neurol., Harvard Med. Sch., Boston, Mass.]

A solution of $^{64}\text{CuCl}_2$ was given by mouth to 4 control subjects and 5 patients, and intravenously to 2 controls and one patient with Wilson's disease (hepatolenticular degeneration). Radio-activity was estimated in plasma and urine.

The plasma radio-activity when $^{64}\text{CuCl}_2$ was given by mouth rose rapidly to a peak about 1 hr. later in the controls, fell sharply and then more gradually, and in 3 again rose later. The patients with Wilson's disease showed somewhat similar variations except that in 2 there was no secondary rise and 1 had a very slow rate of fall. Plasma radio-activity declined rapidly after intravenous administration in the patient and in the controls. Fractionation of plasma by half saturation with $(\text{NH}_4)_2\text{SO}_4$ showed that in the controls most of the activity in the early samples was in the albumin fraction; after 24 hr. it was mostly in the globulin fraction, with which caeruloplasmin, the copper-containing protein, is precipitated. The patient with Wilson's disease had most activity in the albumin fraction even after 24 hr.

The amount of ^{64}Cu excreted in the urine varied from hour to hour and was unrelated to the plasma concentration. The concentration and rate of excretion were much higher in the patients than in the controls.—A. Hepburn.

WYNNE, K. N. and MCCLYMONT, G. L. **Copper-molybdenum-sulphate interaction, in induction of hypocuprosis.** *Nature*, 1955, **175**, 471-472. [Nutrit. Res. Lab., Vet. Res. Stat., Glenfield, N.S.W.]

Copper deficiency has been diagnosed in sheep on pastures in New South Wales containing 3 to 10 p.p.m. Cu, 3 to 9 p.p.m. Mo and 0.1 to 0.7 per cent. sulphate. Merino sheep in pens were given a diet of wheat chaff 40, wheat 24, oats 30, meal 5, urea 0.75, limestone 0.5 and salt 0.25 parts, with vitamin A and Co, with Cu 6 p.p.m., Mo 0.7 or 5 p.p.m. and sulphate 0.04 or 0.4 per cent. The high-sulphate groups on both Mo intakes showed the most pronounced fall in liver Cu content after 4 months, and their blood Cu rose. Sheep restricted to half the feed intake of the other group on the ration with 5 p.p.m. Mo and 0.4 per cent. sulphate also showed the fall in liver Cu, suggesting that it is the proportions of these constituents which are important and not the absolute intakes.

The levels used in this experiment are closer to those encountered in the field, but otherwise the results agree with those of Dick (Abst. 2518, Vol. 24).—D. Duncan.

OTHER MINERALS

3917

MAHALANOBIS, S. K. and ROY, R. N. **Effect of selenium on haemoglobin level.** *Indian J. Physiol. Allied Sci.*, 1954, **8**, 57-60. [Dept. Physiol., Univ. Coll. Sci., Calcutta.]

In 8 rats which received in the diet 200 mg. selenium per kg. bodyweight for 45 days there were falls in Hb value, red blood cell (RBC) count and weight. Normal values were restored 15 days after withdrawal of Se. Daily intramuscular injections of 0.1 mg. Se for 15 days did not affect Hb and RBC count, but deaths occurred within 2 hr. when the dose was increased to 0.2 mg. Intramuscular injection of CoCl_2 even after injection of Se raised the Hb value and RBC count.

MACHLIN, L. J., PEARSON, P. B. and DENTON, C. A. **The utilization of sulfate sulfur for the synthesis of taurine in the developing chick embryo.** *J. Biol. Chem.*, 1955, **212**, 469-475. [Animal and Poultry Husb. Res. Branch, Agric. Res. Serv., U.S. Dept. Agric., Beltsville, Md.]

The distribution of ^{35}S in eggs during incubation was estimated after injection of $\text{Na}_2^{35}\text{SO}_4$ into the whites. In the developing embryo both sulphate and organic S increased, the latter containing in the day-old chicken 65 per cent. of the dose injected. Chromatographic fractions corresponding to methionine and cystine were inactive. Taurine was crystallised and found to be the radio-active organic substance. It was not bound to protein, but most of the sulphate occurred as a protein complex.—A. Hepburn.

LOWE, I. P. and ROBERTS, E. Incorporation of radioactive sulfate sulfur into taurine and other substances in the chick embryo. *J. Biol. Chem.*, 1955, **212**, 477-483. [Wernse Lab. Cancer Res., Sch. Med., Washington Univ., St. Louis, Mo.]

Taurine and unknown radio-active substances were identified chromatographically in extracts of chick embryos 30 min. after injection of sulphate labelled with ^{35}S . Methionine, cystine and glutathione, free or in the form of protein, were not

active even after 24 hr. Autoradiographs of leg bones from embryos showed activity in areas corresponding to cartilage after 30 min. Incubation of homogenates of embryos with pyruvate, acetate and ^{35}S -sulphate produced several active substances, but not taurine. Coenzyme A, adenosinetriphosphate and diphosphopyridine nucleotide added to homogenates significantly increased the amount of radio-activity in the largest unidentified spot on the chromatograms.

ACID BASE EQUILIBRIUM

3920

GRIBBEL, W. Die diätetische und balneologische Beeinflussbarkeit des Säure-Basen-Haushalts als Möglichkeit unspezifischer Therapie. [Dietetic and balneological modification of acid base equilibrium as a possible non-specific treatment.] *Ztschr. ges. exp. Med.*, 1954-55, **125**, 289-304. [Hautklin., Univ. Freiburg i. Br.]

Of the 7 experiments described, 3, in which the author served as subject, were studies of the effect of diet on acid base equilibrium, as indicated by the acidity quotient of the urine (titratable H ions $\times 100$ /titratable OH ions) and a corresponding quotient in which ammonia excretion is taken into account. The results are shown graphically. The treatments were: (1) 13 days of a uniform strongly acid-producing diet, combined in the second week with special baths; (2) after an intervening day of ordinary diet, 6 days of strongly alkaline diet; (3) 4 days of acid-producing diet less rigorous than before.

The shift to the acid side as a result of the acid-producing diet was gradual; after the first week there was little further change. The curves illustrate the predominant effect on the acidity quotient of secretion of HCl by the stomach. After the long period of acid-producing diet, it took 5 days of alkaline diet for large amounts of base to be excreted. The results of the third experiment were like those of the first, but slighter. The other 4 experiments were on the effect of different special baths on acid-base equilibrium.

Acid-producing and alkaline diets in alternate periods of about 6 days are suggested as unspecific treatment for certain skin disorders.

SCHWAB, M., KOCH, R., KOCH, K. E., GÖLTNER, E. and RIGGERT, H. Der Einfluss der Ammoniumchlorid-Acidose auf Gesamtwasser, extra- und intracelluläres Flüssigkeitsvolumen und extracelluläre Elektrolyte. [Effect of ammonium

chloride acidosis on total water, extracellular and intracellular fluid volume and extracellular electrolytes.] *Arch. exp. Pathol. Pharmacol.*, 1954, **223**, 425-442. [Med. Klin., Univ. Göttingen.]

Eleven women were given 10 g. NH_4Cl on 3 successive days between the 2 periods of 3 days on which studies were made; 8 controls received no drug between the 2 periods of investigation. In the subjects receiving NH_4Cl bodyweight fell by 1.1 kg., mean total water by 1.25 litre to 30.09 litres and extracellular fluid by 1.25 to 8.33 litres, while intracellular fluid volume remained constant at 21.8 litres. Thus the loss of bodyweight and total water was due solely to diminution in volume of extracellular fluid. A diminution of 251.4 m. equiv. in the amount of Na in the extracellular fluid is explained by the Na content of the excreted fluid, and by increased Na excretion for the neutralisation of the extra chloride excreted. The data indicate that the loss of base is the primary result of taking NH_4Cl , with increased water excretion as a consequence. The tendency to low-chloride alkalosis resulting from the use of a mercury diuretic can be averted by giving NH_4Cl also.—M. B. Richards.

COOKE, R. E., SEGAR, W. E., REED, C., ETZWILER, D. D., VITA, M., BRUSLOW, S. and DARROW, D. C. The role of potassium in the prevention of alkalosis. *Amer. J. Med.*, 1954, **17**, 180-195. [Dept. Paediat., Sch. Med., Yale Univ., New Haven, Conn.]

Groups of rats on a low-electrolyte diet were given drinking water containing a large concentration of NaHCO_3 and different amounts of K and Cl. Alkalosis developed only in rats with inadequate intakes of K as shown by low muscle K. Less K was required to prevent alkalosis when Cl intake was moderate than when Cl intake was restricted, but when K intake was restricted increase of Cl intake did not prevent alkalosis.

Injection of 15 mM NaHCO_3 per kg. bodyweight into normal and K-deficient rats produced alkalosis in the latter within 12 hr. The normal rats excreted Na and K, but no Cl, in the 12 hr. The K-deficient rats excreted less Na, no K and 1 m. equiv. Cl per kg. bodyweight.

Alkalosis with low blood Cl in K-deficient rats was corrected by injection of KHCO_3 . In these

animals serum bicarbonate fell to normal and serum Cl rose to normal. There was no change in muscle Cl. There was relatively little increase in bicarbonate excretion. Cation was excreted with organic anion, a large part of which was citrate.—F. C. Aitken.

BENTLEY, P. J. Some aspects of the water metabolism of an Australian marsupial *Setonix brachyurus*. *J. Physiol.*, 1955, 127, 1-10. [Dept. Zool., Univ. W. Australia.]

A large population of the small kangaroo *Setonix brachyurus* lives on the island of Rottnest, off Western Australia, where there is much salt or brackish water but only one perennial source of fresh water. In summer it is hot and dry.

The kidney is of primitive mammalian type, with small glomerular volume and high tubular weight relative to bodyweight. Animals caught in winter excreted urine at about 25 ml. per hr., with mean
